The addition of the grounds of the Queen's Cottage at Kew to the Royal Gardens is not, in the opinion of Mr. W. H. Hudson, likely to prove an unmixed benefit, and his position as an ornithologist entitles the views to which he may give expression to careful consideration. These grounds form one of the three nearly perfect fragments of unspoilt Nature and harbours of refuge of all wild creatures which exist on the borders of the metropolis, and Mr. Hudson states that in them he has counted forty three species of birds that breed annually. These include the pheasant, partridge, carrion crow, jay, green woodpecker, wry neck, nuthatch, nightingale, and other shy birds that have become rare in the neighbourhood of London. Whilst he has counted forty-three species, he believes that a full list would number forty-seven species, and it is due to this sanctuary, where the birds breed unmolested, that so many species are to be seen and heard at Kew. Mr. Hudson believes that a grave mistake will be made if the visitors are to have unrestricted liberty in the use of the grounds, and suggests that they should be confined to the walks and green drives. It is no small boon, he says, and properly so, to the visitors from London—the tired workers with brain or hand in search of refreshment to body or mind—to see its masses of verdure and shade, old ivy-grown trees, unkept bramble, furze, and holly bushes, and to hear the enlivening sounds of wild bird and animal life. There has been no obstruction to sight of any description between the gardens to which the visitors have access and the grounds, which were private only in a restricted sense, and the public so far as seeing and hearing go, have always been in the enjoyment of this open space. Mr. Hudson submits that he does not urge the importance of maintaining this spot as a sanctuary for wild life, so much in the interest of the ornithologist, the artist, and the lover of the picturesque, as in that of the myriads of workers, who, being bound to London, have but few opportunities for obtaining a glimpse of unadulterated Nature. The authorities are urged to hand down this gift of the Queen to posterity as nearly as possible in the condition in which it has been received, and this, he contends, can only be done by imposing some restrictions upon visitors. Anticipating the contention that the dwellers in the metropolis are in want of more open spaces, therefore of this one, and that to deprive them of the opportunity to roam at will among the trees, or to sit on the grass, would be to take away the value of the gift, it is pointed out that these grounds form an infinitesimal portion of the six thousand acres to which the public have free access southwest of the metropolis. There is much in the views expressed by this distinguished ornithologist that deserves attention, for it is in the highest degree desirable that where possible all that remains of unadulterated Nature near London should be preserved. We, however, do not share in his apprehensions as to the effect the admission of the public will have upon the birds and animals that have hitherto found a safe retreat within their boundaries, for the Queen's Cottage is situate in the most remote corner of the gardens, which comparatively few visitors explore during the early spring months.

THE INDEBTEDNESS OF ARCHITECTURE TO THE GARDEN.

It is said that the idea of the Corinthian column in architecture was suggested by a sight of the leaves of Acanthus Ispinosus growing about a pot. The acanthus is an ancient plant, for it was known both to the Greeks and Romans, who employed it for decorative purposes; and on one occasion the leaves of this plant having entwined themselves in a graceful way about some support standing by them, suggested to Callimachus the Corinthian capital. It was probably A. mollis which suggested the design of the capital, as both Greeks and Romans made use of this species, forming garlands of its leaves, with which they clothed their buildings, their furniture, and even their clothing. Virgil narrates that the acanthus formed the basis of a design embroidered on the mantle of Helen of Troy; and tells us that the handles of Alcimedon's cup were enwreathed with what he elsewhere terms the "Smiling acanthus." Whether the tradition connected with this plant be true or not, it is scarcely necessary to inquire; certain it is that architecture owes much of its beauty, much of its perfection, to flowers, foliage, and trees. Nature in the garden, in the park, and in the wide expanse of country scenery affords one of the best assistant schools of pure taste; not only to the architect in his outline, and in his enrichment, but to artists connected with almost every branch of manufacture in which embellishment is demanded. The history of the origin of the Corinthian order, which might possibly be contrived to give an interest to the invention, though so often repeated, and so well known, may, nevertheless, be here told once more as a pleasing anecdote of ancient manners. A young maiden of Corinth having died her mother or nurse collected in a basket the toys which she was fond of while alive, and carried them to her grave, where she left the basket covered with a tile, to preserve it contents from the weather. The basket, it is said, happened to be set upon a plant of acanthus. The plant thus being depressed in the middle, its leaves and stalks spread outwards, and grew up around the sides of the basket till they were bent down by the tile which lay projecting over its top. At that time Callimachus, the sculptor, chanced to pass by the grave, and being pleased with the agreeable appearance of the foliage and novelty of the form, he converted it to the purposes of architecture; and having made some columns of a more delicate proportion than had been used before, he adopted the basket and leaves of the acanthus for the capital, and thus established the symmetry and ornaments of the Corinthian order. It is by no means impossible that architecture may have owed the origin of the arch, pointed and circular, to the natural outlines of trees. The wooded avenue, and rows of forest trees not unfrequently represent arches of the most magnificent character, the contemplation of which can never fail to interest and gratify the cultivated mind.

FRUIT AND VEGETABLE IMPORTS.

THE Board of Trade returns for March are better than were those for the first two months of the year, but they again show a falling off in the exports of British and Irish produce and manufactures, the aggregate value of the decrease being £813,408. There is, on the other hand, a material increase in the value of imports, and a small increase in that of the exports of foreign and colonial merchandise. The increases and decreases of the produce in which we are specially interested are about equally balanced, and we have again to record a large drop in the import of apples, and a material augmentation in the supplies of potatos. The imports of apples amounted to 160,779 bushels of the value of £51,778, against 618,219 bushels of the value of £152,978 in the corresponding month of last year, There was also a considerable drop in the imports of grapes, for during the month we only received 1,649 bushels as compared with 3,205 bushels last year, the value being £3,445 and £5,991 respectively. Pears, on the other hand, show an increase, for 3,153 bushels were imported, against 1,796 bushels last year and 124 bushels in 1896, but there was a material drop in relative values, more especially when compared with the imports in the year last named, when they were returned as worth twenty shillings per bushel. Plums were imported in much larger quantities than in the corresponding month of any previous year, the aggregate imports amounting to 90 bushels, against six bushels in March 1897. It is of interest to observe that with the augmentation in quantity there has been an enlargement in relative value, for while the six bushels are returned as of the value of £18, or £3 per bushel, that of the 90 bushels is entered at £408, or considerably over £4 per bushel. Unenumerated fruits continue to increase, and the quantities received aggregated 68,701 bushels of the value of £35,849. Immense quantities of potatos were again received, the total for the month being 635,872 cwt., against 45,203 cwt. received last year. Germany sent us 321,310 cwt., and France 86,448 cwt., but from the Channel Islands we only received 782 cwt. Onions were received in smaller quantities than in the corresponding month of the two preceding years, but it is satisfactory to observe that there was a material increase in values. Butter, bacon, cheese, eggs, and other minor products of the farm, continue to be received from abroad in enormous quantities, as indicated by the fact that the value of the latter, imported last month was of the value of £1,510,589.

Ghent Quinquennial Horticultural Exhibition.—As we are going to press our special correspondent cables that the preparations for the great exhibition which opens at Ghent on Saturday are well advanced, and that there can now be no doubt, as suggested in our issue of the 9th inst., that the gathering will be the most important of the magnificent exhibitions that have been held under the auspices of the Royal Agricultural and Botanical Society of Ghent. Already a considerable number of the members of the jury have assembled in the city and are to be found exploring the numerous commercial establishments in its vicinity, or inspecting the many objects of interest other than those relating to horticulture. The jury consists of two hundred and eleven members, and comprises the most distinguished horticulturists in Europe. According to our Belgian contemporary, *La Semaine Horticole*, the members of the jury include thirty British, fifty-four Belgian, sixty-seven French, twenty-five German, sixteen Dutch, six Italian, four Russian, four Swiss, three Luxembourg, and two Sweedish horticulturists, with delegates from Austria, Brazil, Spain, and Japan. The programme arranged for the period over which the exhibition extends, is full and well devised. The members of the jury will assemble at the Casino where the exhibition will be held, at 9 a.m. on Friday the 15th inst., and the judging will be proceeded with shortly after that hour. At the luncheon to the jury, on the completion of the judging on that day, the Veitch medals conferred upon Comte de Kerchove, M. Ed. André, and M. Latour Marliac by the Veitch Memorial trustees, will be presented. On Saturday His Majesty the King of the Belgians, will visit the Casino at 8 a.m. for the purpose of a private view and meeting the jury, and at 10 a.m. he will formally announce the opening of the exhibition. On the evening of the same day an International Raout will be held under the auspices of the Chambre Syndicale des Horticulteurs Belges at 8 p.m., at the Société Union, Place d'Armes, Ghent, and for this gathering evening dress is prescribed. A concert will be given at noon in the Place d'Armes on Sunday the 17th inst., and in the evening the jury will be entertained at a banquet in the salon of the Grand Theatre, at which several of the Ministers of State will be present. It is anticipated that the King of the Belgians will give a garden party at Laeken on the 17th inst., to which the diplomatic body and the members of the jury will be invited. Monday, the 18th inst., is an open day, but on Tuesday, the 19th inst., there will be an excursion to Brussels, and the members of the party will visit the glass houses in the gardens of the King's residence at Laeken. The members of the jury will have free admission to the Botanic Garden, Hotel de Ville, Belfry, the ruins of the Abbey of St. Bavon, and the museums of the city of Ghent. They will also have admission to the Comtesse de [illegible] winter garden, at Ghent, from 18th to 24th inst.; and they will have access to the Concord and Union Clubs, and the rooms of the Société Royale des Melomanes, during the time the exhibition is open. A full and special report of the Ghent Exhibition will appear in our next issue.

Boxes of Flowers from the Riviera have, until the commencement of the present month, been dispatched during the winter to friends at home at a very cheap rate. Thousands of such boxes, not exceeding three-quarters of a pound, were sent weekly as "samples of no value" at the rate of about 3½d. each, much to the pleasure of those who could not leave this country for the more favoured health resort. On April 1, however, orders were issued from the G.P.O. that all such boxes were to be refused admission into England, and returned to the senders. Whatever the legal rights of the Post Office authorities to stop such parcels, it seems an extremely harsh proceeding on their part to exercise their authority without due notice, and before the season of sending flowers from France and Italy to Britain was at an end. Unless alterations are made in the tariff flowers costing 3½d for postage home will in future cost 1s. 4d. per parcels post.

Open Spaces in London continue to receive the close attention of the Metropolitan Public Gardens Association, and at the monthly meeting held the other day it was announced that, as the result of the representation of the association, the Home Secretary had refused to sanction the Cross Bones Burial Ground, Southwark, being built upon. It was also reported that progress had been made in the laying out of several grounds, and it was stated that Charles Square, Hoxton, had been commenced, and that trees had been planted in the new riverside ground at Putney. It was agreed, if its maintenance were secured, and if funds were forthcoming, to lay out the churchyard of St. Mary, Plaistow, at a cost of about £300. Amongst many other matters which engaged the attention of the meeting may be mentioned Ham-common and Lammas Lands, Bridgewater Square, the "Postmen's Park," Pymme's Park, Edmonton, and some vacant land at New Cross.

The Sources of Commercial India Rubber will be fully explained by Dr. D. Morris, C.M.G., Assistant Director of the Royal Gardens, Kew, in two Cantor lectures to be delivered before the Society of Arts, John Street, Adelphi, on April 18 and 25. The lectures commence at 8 o'clock.

Royal Sovereign Strawberries were selling for 7s. 6d. per basket of eighteen fruits in the leading West-end fruiterers' shops a few days ago. At the same time, home-grown green peas and French beans were realising extremely high prices, while large bunches of giant asparagus sold for a guinea each. Not a few of the market gardeners who grow largely under glass have been making handsome profits upon early green pea and French bean culture, as the season has been a good one for those growers outside the metropolitan fog area.

A New Cactus Society, to be known as the Bath and West of England Cactus Society, is being formed for the promotion of the cultivation of cacti and other succulents. This new body will be affiliated with the National Cactus Society, and it proposes to hold an exhibition in connection with the Bath Rose Show on June 23 next.

Memorial to the late M. Jean Linden.—Under the presidency of Comte Oswald de Kerchove de Denterghem, a committee has been formed to consider in what manner a most fitting memorial can be raised to the late M. Jean Linden, as a recognition of the services he rendered to horticultural and botanical science. The committee consists of such well-known gentlemen as MM. le Comte de Bousies, de Middeleer, Dutrieu de Terdonck, Kegeljan, Lubbers, Massange de Louvrex, Baron Osy de Zeegwart, and Warocque. M. Kegeljan is treasurer and M. Lubbers, secretary of the Société Royale de Flore de Bruxelles, is secretary. The co-operation of all botanists and horticulturists, both professional and amateur, both in Belgium and other countries, is desired so that the memorial may be of an international character.

A Botanic Garden at Nantes is to be established immediately and [illegible] on the lines of the Royal Gardens, Kew. A rich citizen of Nantes is incurring the initial expense, and it is proposed to cultivate here such plants as are likely to prove of service in the French colonies.

The Apricot Crop.—Our coadjutor, Mr. A. W. Ward, Stoke Edith Park, writes: In spite of the untoward weather that prevailed more or less throughout the month of March, apricots have passed through the ordeal remarkably well. Although as much as 14 degrees of frost was registered on one occasion, the [illegible] sustained no harm, they being well sheltered by Frigi Domo blinds, while the [illegible] broke the force of the bitter cold north-east winds which blew so persistently during the past month. But little rain fell during March, and the heavy snow storms which swept over various parts of the country affected this district to a slight degree only. What snow fell could not reach the blossoms as the blinds were kept drawn so long as the storm lasted. They were thus kept dry, and the sharp frost which succeeded the storm the next morning left them uninjured. The blossoming has been one of great profusion, both spurs and young wood being covered with flowers, which were strong, bold, and well developed. The weather was too cold for the bees to put in but an occasional appearance to assist in the setting of the blooms; all the same a heavy crop has been secured, and quite equal to the phenomenal one of 1896. Protection is still accorded the trees at night and will be for some few weeks longer, until a sufficient quantity of foliage has developed and become hardened enough to protect the fruits. The latter are now swelling apace, and in the course of a week or ten days the first thinning will be done, when all that are badly placed will be removed, and the twins, [illegible], and clusters of fruits thinned down.

A Memorial to Marcello Malpighi, the celebrated botanist and biologist, has just been completed. It is a volume filled with information concerning a great scientist and philosopher who lived and worked during the latter half of the seventeenth century,and as a memorial it will be more widely appreciated than the fine bronze statue erected to Malpighi at Crevalore last autumn. This memorial volume contains contributions by Professors Atti, Virchow, Haeckel, De Michelis, Todaro, de Giovanni, Weiss, Kölliker, Romiti, Eternod, Cattaneo, Perroncito, and Pizzoli. These deal with the life of Malpighi or his work in biology, pathology, histology, comparative anatomy, and in connection with the silkworm. The comparative merits of Malpighi and Nathaniel Grew are discussed by Professor Strasburger, especially in connection with their views upon the anatomy of plants. Professor Morini deals in detail with the botanical studies of Malpighi, and shows the condition of botanical science ere Malpighi commenced his studies. Of special interest to us is the account of Malpighi's relations with the Royal Society, presented by Professor Michael Foster; this contains forty-two letters that passed between Malpighi and the Royal Society. The work, printed in Italian, concludes with a bibliography and an account of medals struck in honour of Marcello Malpighi.

Flowers in New York at Eastertide are sold in enormous quantities for church, home, and personal decoration, and it has been estimated that the city and suburbs expend at least a million dollars during Holy week upon flowers, foliage, and growing plants. The most popular flowers are the pure white blooms of Lilium longiflorum Harrisi, and the big spathes of Richardia æthiopica; lily of the valley, azaleas, and violets are in great request, the latter being scarcely produced in sufficient quantity to meet the immense demand. Roses on long stems are in great demand at Eastertide, and the varieties most required this season have been American Beauty, President Carnot, Bridesmaid, General Jacqueminot, Ulrich Brunner, Catherine Mermet, and Mrs. Grant. Carnations, tulips, hyacinths, daffodils and jonquils, sprays of forsythia, staphylea, deutzia, smilax, asparagus, and fern fronds are all present in enormous quantities, and find a ready sale at moderate prices, for the days of extravagant profits are over.

Vanda Miss Joaquim, the interesting and beautiful hybrid, raised artificially, between V. teres and V. Hookeriana is admirably figured in the current double number of the *Lindenia.* Cattleya Mendeli var. Empress Queen is finely figured in the same issue, and is noted for the large and dark apex of the lip. Other orchids pourtrayed are Oncidium Batemannianum, a lovely species often met with in gardens under the name of O. Saintlegerianum; Odontoglossum Thibaultianum, no doubt a natural hybrid between O. crispum and O. odoratum; Saccolabium giganteum Petotianum, a beautiful albino variety; Cattleya Hardyana Reginæ, dedicated to the Queen of the Belgians; Cymbidium pendulum, a somewhat uncommon plant, with depending racemes of white and purple flowers; and Lælio-cattleya Pallas inversa, the reverse cross to the original hybrid; this was raised by Mons. Mantin, the original by Messrs. J. Veitch and Sons.

Dr. R. Hamilton Ramsey, the genial and hard-working president of the Torquay Gardeners' Association, was recently presented, on behalf of a hundred and thirty-three members of the association, with a magnificently framed and richly illuminated address, as a token of their personal esteem and regard, and in acknowledgment and appreciation of the invaluable services rendered by him to the association as its president. The presentation was made at the sixth annual meeting.

The Colony of Newfoundland is now very largely in the hands of one man, Mr. William Reid, the son of a famous Canadian contractor, and himself a great contractor. When constructing a railway for the colony Mr. Reid was paid fifteen thousand dollars per mile, and no less than two and a half million acres of land, with the right to select the land himself. Mr. Reid now owns gigantic coal fields, dry dock, telegraph system, a great part of the railway, a small fleet of steamers, and an electric railway; with all these in good working order, he has now time to turn attention to his enormous forests on the land already referred to, for these, as lumber and pulp mean a huge fortune in themselves.

Brown Turkey Figs of high quality and good size were submitted to the Fruit and Vegetable Committee of the R.H.S. on April 12 last by Mr. J. F. McLeod, gardener to J. Pierpont Morgan, Esq., Dover House, Roehampton. About three dozen examples in prime condition were staged, and these were culled from a tree that covers a space six feet by eighteen feet, and has a crop of four hundred and seventy fruits all of fair average size. Mr. McLeod is as capable a fruit grower as he is a plantsman, and that is saying a good deal.

New Park for Lee.—We recently stated that the Earl of Northbrook and Viscount Baring had offered to present to the public, in commemoration of the Diamond Jubilee of her Majesty the Queen, a piece of land nearly seven acres in extent in Bromley Road, Lee, for the purpose of a recreation ground. Later advices show that the only conditions attached to the gift are that the ground should be taken over by the Council and laid out and properly maintained by it as a recreation ground, and that the costs of Lord Northbrook's solicitor and surveyor should be borne by the Council. Building operations were going on in the district, and there was a Board School close by. In the circumstances the London County Council Parks Committee did not hesitate to suggest that the Council should undertake the charge of the land on behalf of the public. It was estimated that the value of the land to be presented to the Council was £4,125, and that the solicitor's and surveyor's charges would therefore be about forty guineas and twenty-five guineas respectively. There might, however, be some other slight expense, and they therefore asked for a vote of £100 in order to cover all possible outgoings. They estimated the cost of laying out the land, including fencing, seats, and watch box, at £1,000, and the annual cost for maintenance at £200.

NEW PLANTS AND FLOWERS.

Eulophiella Peetersiana.

A magnificent orchid, the spike carrying over two dozen flowers and buds; it is from three to four feet long, and each flower measures three and three quarter inches across. The segments are equal, spreading, rounded at the apices, broad, and of a rich but soft purplish-rose colour; the tips of the sepals have a crimson flush at their centres. Lip white inside and whitish underneath, the side lobes rosy at the outer tips, and the front lobe also coloured soft purplish rose. In the throat are six long lines of dull brownish yellow, terminating in several tooth-like prominences at the base of the apical lobe. This is a Madagascar orchid discovered by M. Hamelin, and to Sir Trevor Lawrence belongs the honour of first flowering it in cultivation. F.C.C., R.H.S., April 12. Mr. W. H. White, orchid grower to Sir Trevor Lawrence, Bart.. Burford Lodge, Dorking

Cypripedium Olenus magnificum.

A superb cypripede, and, no doubt, the grandest of the hybrids in which C. bellatulum has been a parent. It is the result of crossing C. bellatulum with C. ciliolare. The flowers measure five inches across. The dorsal sepal is hooded, orbicular, pointed, white-ground, but this almost obliterated, especially in the centre and base, by the intense claret-purple veins and shading. The broad petals have rounded apices; the ground colour is white, tinged with rose, but this is only noticeable towards the apex owing to the shading, spotting, and veining of claret-purple, the latter colour almost covers the basal half, and is very bright and polished. Foliage, strong, light green, mottled and tesselated with dark green. F.C.C., R.H.S., April 12. Mr. W. H. White, orchid grower to Sir Trevor Lawrence, Bart., Dorking.

Phalænopsis Stuartiano-Manni.

An interesting hybrid between P. Stuartiana and P. Manni. The flowers of the latter have been enlarged, and the segments broadened by the influence of the former, and the green colour has been lightened considerably. The sepals and petals are about an inch long, palest green, dotted with brown; lip brown with a white tip; side lobes small, white edged, and lined inside with rich red brown. A.M., R.H.S., April 12. Messrs. J. Veitch and Sons, Chelsea.

Epidendrum elegantulum leuchochilum.

An albino form of the typical hybrid between E. Endresio-Wallisi and E. Wallisi. The sepals and petals are pale creamy green, and the lip is purest white, with a tiny golden disk. A.M., R.H.S., April 12. Messrs. J. Veitch and Sons, Chelsea.

Masdevallia ventriculata var. longicaudata.

A tiny orchid to have such a long name. It is a small grower, and has dull crimson flowers, tubular, and with three long greenish tails. B.C., R.H.S., April 12. Mr. W. H. White, Burford Lodge Gardens.

Dendrobium Aspasia var. Langleyensis.

A lovely dendrobe, with yellow sepals and petals, and rich golden centre to the lip. The sepals and petals are half an inch broad, and of the palest nankeen yellow. Lip, rich golden-tinted orange with red-brown blotches at the base. A.M., R.H.S., April 12. Messrs. J. Veitch and Sons, Chelsea.

Odontoglossum Wilckeanum Pitt's var.

A splendid odontoglot, with flowers three and a half inches across, yellow, with crimson-chocolate spots and blotches. The sepals are broad, but acutely pointed; the ground colour is yellow, and on this are some very large crimson-chocolate blotches; the petals are pale yellow, and the markings smaller and a little brighter; the margins of the petals are fringed. Lip palest yellow, with a red-brown blotch. F.C.C., R.H.S., April 12. Mr. H. T. Pitt, Stamford Hill.

Phalænopsis Schroderæ.

A very pretty phalænopsis, with palest rose flowers and brighter rose lip. This is the result of a cross between P. leucorrhoda and P. intermedia Portei. The sepals are nearly white, but the petals have a rose tinge. The side lobes of the lip are spotted with brown at the base, and veined with rose at the apex; the front lobe has a greenish-yellow tinge at the base, but down the centre are veins of deepest rose. A.M., R.H.S., April 12. Messrs. Low and Co., Bush Hill Park, Enfield.

Daffodils.

Lady Helen Vincent.—A fine Ajax form, with sulphur yellow and spreading perianth, and rich yellow corona, long and waved at the mouth. A.M., R.H.S., April 12. Messrs. Barr and Son, Covent Garden

Homer is a lovely form of the poeticus race, with very broad pure white segments, and an orange crown edged with deep scarlet. F.C.C., R.H.S., April 12. Rev. G. Engleheart.

Oriflamme.—A somewhat small-crowned form, with fine orange corona and spreading creamy segments; this is an incomparabilis form. A.M., R.H.S., April 12. Rev. G. Engleheart.

White Queen has a fairly large trumpet, very broad and prettily frilled at the mouth; the colour is pale yellow at opening, fading to rich cream colour. Perianth spreading and segments broad, French white in colour. F.C.C., R.H.S., April 12. Rev. G. Engleheart.

Lucifer.—A lovely narciss that suggests Sir Watkin, but is more refined. The spreading segments are pale sulphur, shading to cream; trumpet short, richest orange, waved at the mouth. A.M., R.H.S., April 12. Rev. G. Engleheart.

Lady Margaret Boscawen.—This is a noble bicolor, with very broad and spreading perianth of a French white shade. Trumpet clear, golden colour. F.C.C., R.H.S., April 12. Rev. G. Engleheart, Andoversford.

Dracæna aureo-striata.

A handsome dracæna in the way of D. Lindeni, the broad recurving leaves having numerous long bands of yellow with other bands pale of green and broad ones of deep but bright green. The yellow colour fades slightly as the leaves age, but they still retain their beauty. A.M., R.H.S., April 12. Messrs. Hugh Low and Co., Bush Hill Park, Enfield.

Hippeastrum Daones.

A handsome form with broad substantial segments that have irregular white margins and bases, but are otherwise coloured rich scarlet with deeper veins; a beautiful variety. A.M., R.H.S., April 12. Messrs. J. Veitch and Sons, Chelsea.

Camellias.

Mrs. J. Buchanan is a beautiful semi-double camellia, white ground with rich scarlet and crimson stripes and specks.

Pride of Waltham, a charming flesh-pink camellia of large size and very double; the petals are pointed and the veins of a deep rose shade.

Duchess of Teck is a bright rose pink camellia of good shape and with faint red veins along the margins of the segments. A.M., R.H.S. to each, April 12. Messrs. W. Paul and Son, Waltham Cross.

FAILURE OF FLOWER CROP OF THE ISLANDS OF SCILLY.

NEVER since the commencement of the culture of narcissus for cut flowers by the Scillonians has the crop been so light as this season. There are many theories about the phenomenal failure, and some people are pessimistic enough to believe that the culture of flowers in the Scilly Islands is doomed, concluding the soil or bulbs are entirely exhausted; others think that a change of culture is imperative, otherwise the flower crop will always be light in future. Without, however, ignoring the great benefit narcissus would derive through a change of soil and rotation of crops, I may, perhaps, venture to say that the direct cause of this season's failure is undoubtedly climatic influence. The winter of 1897 was mild, though dry, and what with an exceptionally dry spring and early summer, together with heavy March gales, early maturity, and consequently weakening of bulbs, resulted, so that I never have seen smaller and poorer bulbs than last summer. In dry exposed places, of weak-growing sorts, such as Narcissus poeticus ornatus or incomparabilis, the last year's flowering bulbs have entirely disappeared, leaving only the non-flowering offsets struggling on for existence. On the other hand, where properly sheltered from gales and sea-spray, and in a deeper and more retentive soil, the slight crop has been less apparent this season in Scilly; but, of course, here, as in agriculture, with the best of soils, unless well-managed the crop is often poor in the best of seasons.

Owing to long connection with the firm of Mr. Ware, of Tottenham, who has done much to increase the flower trade of Scilly, I can speak with experience, and I must say that I have seen very few places where less trouble is taken with flower culture than in Scilly, and the treatment is often most injudicious. The bulbs are often ploughed out and again ploughed in—at least, it is called ploughing; scratching would be a better term, for the soil is not moved to a greater depth than four or five inches, the sub-soil being hard. As for cleaning; well, this is done by many growers not more than once a year, and should the weeds grow too freely, they are simply mowed down, even when the leaves are still green. As a trial only, I saw clover sown on the beds which would have to be cut long before the leaves of narcissus had turned yellow; I don't suppose the same grower would like to do this with his potatos, which would almost be the same; in the one case we have the bulb for next year's flower, and in the other hand the tuber for food. Strong growing Narcissus Tazetta, or polyanthus forms, like Scilly White, Soleil d'Or, and Grand Monarque, are often left in the same piece of ground for four to six years, and if lifted are mostly replanted in the same ground. The newer hybrids of Ajax, and the Medio coronatæ, these should certainly never be left longer than two to three years; in some cases only for one year, and then be planted in well-prepared ground, which had at least a year's change, with early potatos or another crop.

Owing to the somewhat shallow soil, which is, however, exceptionally good in some localities certain sorts cannot be grown at all to be profitable these should have long been discarded for sorts more adapted to the islands; but one still finds the old common Pheasant's-eye narcissus, Biflorus, Stella, Major with, others grown in localities where they have not produced a crop, ever so light, for years. There are some growers in Scilly who have, with a less heavy crop of flowers this season in comparison to last year's abundance of flowers, nothing to complain of, especially as prices were better; but these were invariably those who take greater trouble with their culture than the majority, but even these would not favourably compare with the industrious French flower-grower of the South of France. With such a matchless climate as that of Scilly all that is wanted is shelter against gales, strong growing sorts of narcissus (early as well as late flowering), and a change of ground, with a certain amount of labour to keep the beds free from weed; I feel well assured that a little more labour bestowed will greatly help to avert another failure like the present one, brought about largely though it be by unfavourable climatic conditions. There is still another matter I wish to draw attention to, and that is the careless way some have of packing flowers when not perfectly dry, or by leaving injured blooms with the perfect flowers; the bulk realising often on this account very poor prices, so poor that I have known cases where the price obtained was not sufficient to cover cost of carriage. The latter is very heavy, but in spite of this Scilly can always hold its own on account of a favourable climate. To sum up, the Scillonians should use more labour and cultivate better, change crops frequently, grow suitable varieties, and pack the flowers more carefully. G. REUTHE.

I have just noticed your article upon the daffodils of the Scilly Isles in the issue of the 2nd inst. and thought that perhaps a few remarks from this district might be of interest to your readers. Firstly, I am rather doubtful as to the failure of the Scilly crop of bloom being due to faulty cultivation, though unable to speak from personal experience. At the last meeting of the R.H.S. I was talking to Messrs. Barr's salesman (Mr. Logan) who said that he had never seen such foliage in his life as he had seen this season on the farms of the Scilly Islands; he also said that one grower had learnt how to grow the variety Henry Irving in a perfectly healthy manner, and now had a stock of some tens of thousands. This man at any rate has got a long way ahead of most cultivators.

I am inclined to think that the season has had much more to do with the failure of crop than improper cultivation; for this reason, namely the complaint of poor blooms, or little of it, seems to be very general. From Lincolnshire, Hampshire, and our own neighbourhood one hears bad reports, especially with regard to the early kinds.

Our own stock certainly looks far below the average; neither foliage nor buds look really promising. This is the more noticeable in the [illegible] kinds, the later ones, such as Empress, Emperor, Bicolor, Grandee, [illegible] look about as strong as usual in foliage, but the buds do not give [illegible] the numerous blooms we are favoured sometimes with. My own [illegible] that a very mild winter is bad for the daffodil, the buds become excited into growth too early, and the blooms have not time to develop. Certainly we never had finer blooms than after the severe winter of 1894-95. In that year (1895) the very first bloom to open was on N. minor, on March 25, and we had no quantity of bloom open until as late as April 14, yet when they did come out they were extremely fine. Of course "one swallow does not make a summer," and one season will not prove a theory. I am only comparing two seasons which I have in my mind. It would be interesting if some of your readers in other parts of the country would say how the season is treating their daffodils. The late gales and snowstorms have knocked all the life out of early blooms, the first flowers of Golden Spur, Queen Bess, Mrs. Thompson, &c., were made into pulp. I hope we may have a very favourable ending to the season after such a bad opening.

Chilwell Nurseries, Notts. J. DUNCAN PEARSON.

GARDENERS' ROYAL BENEVOLENT INSTITUTION

"VICTORIAN ERA FUND."

YOUR readers will doubtless remember that this fund was established last year to commemorate the completion of the sixtieth year of her Majesty's beneficent reign. They also will recollect that its object is to temporarily assist unsuccessful candidates, whilst awaiting election, who have been (or their husbands) subscribers to or life members of the institution. The total amount received up to December 31 has been invested, and the committee are glad to be able to announce that the income derivable therefrom this year will enable them to distribute the sum of £106 10s., the first half of which was sent on April 1 to eighteen unsuccessful candidates as follows, and has been divided at the rate of 15s. for each year they (or their husbands) had subscribed:—

	Years self or husband subscribed.	Amount sent April 1, 1898. £	s.	d.
Byran, Andrew ...	13	4	17	6
Nixon, Francis ...	13	4	17	6
Plevy, James ...	12	4	10	0
Staples, George ...	11	4	2	6
Wood, Caroline ...	11	4	2	6
Gibbons, John ...	10	3	15	0
Watt, James ...	10	3	15	0
Hackwell, Elizabeth	9	3	7	6
Wills, George ...	9	3	7	6
Barnfield, Alfred	8	3	0	0
Hatch, Annie ...	8	3	0	0
Mitchell, Lucy ...	7	2	12	6
Shearn, Joseph ...	7	2	12	6
Lee, Alexander ...	5	1	17	6
Evans, Thomas ...	4	1	10	0
Gould, William ...	2	0	15	0
Thomas, William	2	0	15	0
Woodward, Emma	1	0	7	6

From the above it will be seen that the aggregate number of years of subscriptions is one hundred and forty-two, which at 15s. for each year gives a [illegible] of £106 10s., the first instalment of which, as already stated, was sent on April 1 last and the remainder will be sent on October 1 next. The Committee are very anxious to bring up the total amount of this fund to £5,000, to do which they require a sum of £925; and I should like to draw attention to the generous offer made by N. N. Sherwood, Esq. (trustee), to contribute £50, provided the amount required be raised, in response to which the following gentlemen have each kindly promised a similar sum: Arthur W. Sutton, Esq., Reading; Leonard Sutton, Esq., Reading; Harry J. Veitch, Esq. (treasurer); and several smaller contributions have already been received. The Committee sincerely hope that before the close of the year they may be able to announee that the balance to make up the £5,000 has been received. They trust, therefore, that every well-wisher of the institution will note that the "Victorian Era Fund" is still open, and that donations to it will be most gratefully received. The committee also desire again to emphasise the notice which has already appeared in your columns and elsewhere that this fund is intended for the benefit of those only who have subscribed to the institution. GEORGE S. INGRAM, *Secretary.*

AVERAGE LIFE OF A POTATO.

WITH regard to the opinion of Mr. Fidler, which appeared in the GARDENERS' MAGAZINE of March 26, respecting the average life of the potato, which, he says, would be twelve years, I cannot quite agree with him. In the first place we will take the Ashleaf Kidney, which cannot be beaten for earliness, productiveness, and quality. This potato has been cultivated for over sixty years. I tried last year twenty different sorts of potatos, besides eight varieties [illegible] saved seedlings, which promised well for two seasons, but did not give [illegible] satisfaction of the old variety Ashleaf and Gloster Kidney. In the [illegible] I find nothing to come up to the old Irish potato, the Flounder, either [illegible] or quantity; this potato has been grown for many years, is one of the [illegible] and cooks well when quite young. I grew a better crop last year from the [illegible] named three varieties than I have for many years, and my opinion is that [illegible] fully cultivated they will go on as they have done for any number of years. [illegible] we must not pass by the old Scotch Champion, for it is one of the [illegible] potatos of the very best cooking quality, and very productive; [illegible] variety, and as good a cropper now as ever it has been. I find nothing [illegible] crop variety to equal the Magnum Bonum, sent out by Messrs. [illegible] in the year 1876; it cannot be surpassed for late keeping, is very [illegible] disease-resisting potato, and as vigorous a grower now as when [illegible] introduced.

Then we have the Bruce, a splendid potato for main crop and disease resisting; the quality all that can be wished for, and again this is a very old variety. I grow the varieties that answer my purpose the best. I want both quality and quantity, for I need annually from twenty-six to thirty tons, so I have found [illegible] by experience the best croppers. I do not, however, decry the later introduced varieties sent out. Mr. Fidler opines the average life of a potato is twelve years, and after that age a variety loses vigour, no matter how well grown or how carefully the seed is changed. In my opinion, when potatos are well ripened and properly stored during winter, the life of the potato is of much longer [illegible] and I for one do not believe potatos deteriorate. T. DAVI

The Gardens, Castle Hall.

Spontaneous Hybrids of Hardy Plants.

IN a garden like that at Edge Hall, where hardy plants are allowed to shed their seed and the seedlings are only weeded up when they become so thick or so large as to be obstructive, it is natural that many accidental or spontaneous hybrids should be produced between species having close affinity. But plants are curiously capricious in this matter; for we find that many which are closely allied both in appearance and habit, never produce a cross, whilst there are others in the same genus which cross so readily that the seed ripened in this garden can never be depended upon to come true. For instance in the genus Dianthus, D. alpinus and D. neglectus flowering together on the same rockery, do not mix; whilst D. cæsius and D. superbus, and some others are always being transformed. Again I have never seen a cross between Scilla sibirica and S. bifolia, which flower and seed by hundreds in the same border; but S. bifolia crosses abundantly with Chionodoxa Luciliæ. In others, as aquilegia, polemonium, verbascum, the tendency to cross seems general. As regards the fertility of hybrids it is perhaps imprudent to dogmatize; though many are, as far as my experience goes, invariably barren, polemonium, verbascum, campanula, papaver, belonging to this class, whilst others are more or less sparingly fertile, though never constant, either producing an ever-varying progeny, or reverting to one or perhaps both of the parents.

These hybrids of hardy plants generally have the merit of a prolonged flowering season, and, in many cases, of greater vigour of growth and facility of increase by division, than either parent, though it might be too much to assert that this vigour lasts indefinitely, or that they have a duration of existence to be compared to that of a species. It would be difficult to prove this, because similar hybrids are probably produced repeatedly, and duration of life only comes into the question where both parents are perennial; for, as far as I have observed, when the cross is between a perennial and a biennial or annual the plant always follows the shorter-lived parent.

It is impossible in a short notice to speak of all the hybrids I have noticed, but I give particulars of a few of them. All the perennial species of polemonium seem to cross when grown near together. Perhaps the most remarkable fact about them is the readiness with which P. flavum becomes impregnated with the pollen of P. cœruleum, and the exactness with which the seed reproduces the pollen parent, both with blue and with white flowers. The type of P. cœruleum always has what is called an ascending growth, whilst the hybrid has divaricate stalks; but the most obvious and certain distinction is the profuse seeding of the type, and the sterility of the hybrid. Still, the characters so nearly resemble those of the pollen parent that if I had not repeatedly satisfied myself that the seed was produced by P. flavum, I should have thought it incredible. P. reptans, P. humile, and the variety commonly called in gardens P. Richardsoni, all intercross, and some of the results are very neat and distinct border plants. To turn now to verbascum, the readiness with which the Mulleins all cross is well known, and some of the hybrids of biennial kinds are very beautiful, the various colours of V. phœniceum being imparted to the tall branching habit of such biennial species as V. Blattaria and V. Lychnitis, but these are only lucky accidents, which cannot be artificially produced with any certainty as to the result. However, crosses between V. phœniceum and V. nigrum produce true biennials, varying widely in colour, and often having great merit, as they send up a succession of profusely flowering spikes, and may easily be perpetuated by dividing the root into lengths; still, their duration is not for many years.

Poppies sometimes produce interesting hybrids, not only the allied Papaver orientale and P. bracteatum, which if grown from seed ripened in the same garden produce an indiscriminate and intermediate but fertile offspring—or P. nudicaule, P. alpinum, and pyrenaicum, which also assimilate, and are perhaps only varieties of one type, so their crosses are fertile—but also such distinct kinds as the tiny P. caucasicum, which has more than once in my garden produced a cross with P. Rhœas, to die of course at the end of its first flowering, and never producing a seed. But I have a very good perennial hybrid poppy not produced in my garden, although raised there, from seed given me of P. rupifragum, fertilised with pollen of P. orientale. It is intermediate in character, very ornamental, and flowery, being absolutely sterile, but increased slowly by division. Before dismissing poppies I should like to say a word about the very distinct poppy known in gardens as P. umbrosum, from the Caucasus, its botanical name is P. commutatum, and it is now considered a variety of P. Rhœas, but though I have for some years grown it in the same bed with the many coloured P. Rhœas, the two forms continue distinct, and I have never been able to observe any intermediate characters.

Heuchera sanguinea has produced two distinct hybrids in Edge Garden, of both of which it is inferred to be the seed parent, from the fact that the conjectured pollen parents grew at a distance. One is obviously a cross with H. cylindrica, a species having rather large pale-green flowers. This hybrid has pink flowers, not without a suspicion of green; the spikes are produced plentifully all through summer and until late in autumn; the habit is good and intermediate. The other has also pink flowers, but smaller, and the habit of the plant is more diffuse; it was probably from the pollen of H. hispida, or one of the kindred dark-leaved species. It resembles closely what I have seen offered in nurseries by the name of H. brizoides. Both these hybrids are sparingly fertile, and their seeds have come up, but have not yet flowered. The giant Spiræa kamtschatica, which resembles a giant meadow sweet, eight feet high, seems to behave like a plant which produces no pollen in Edge Garden. I have examined the dry plumes without being able to find any seed; but nearly every year two or three seedlings come up near it which have produced pale-pink flowers, the stature being hardly half that of the parent; they seem to be intermediate with S. venusta, and are graceful plants, superior to S. kamtschatica.

Other hybrids of which I have established a stock are Aster Thomsoni with A. amellus, and A. Thomsoni with A. pyrenæus, both of merit, both on account of their habit and elegance, and their flowering season, which lasts from early summer to late in autumn. Both are entirely barren, though I dare not assert that hybrids of asters, which come abundantly in the garden are always barren. Columbines are plants of which every species seems ready to cross with any other in the genus, and the crosses are all fertile. Their flowers are supplied with pollen by the bees as soon as they open, so that no species in the garden can be trusted to reproduce itself, and they undergo from generation to generation endless changes. If, however, the best species, like A. cærulea, are not frequently supplied, the stock has a tendency to deteriorate, and to be merged into the strongest kinds, chiefly the old world A. vulgaris. By eradicating the inferior flowers as soon as they show, and selecting the finest for seed, a good strain is kept up, but the same plant will give seed which produces both stubby short spurred and fine long-spurred flowers. There is no space here to speak at length of hybrid primroses, and the alpine primroses are not happy in the soil and atmosphere of this garden, so get little attention, but many of the genus cross readily; the wild yellow auricula, and the self-purple kinds, probably P. viscosa, cross readily, producing every variety of border auricula. P. rosea and P. denticulata have also crossed, but the mixture was only fit for the rubbish heap. I only mention one more hybrid in conclusion, a very pretty and elegant plant, between Ranunculus amplexicaulis and R. gramineus. The large flower, of citron colour, and the leaf and habit being in all respects half way between the two. It is unfortunately of delicate growth, and hardly seems likely to produce an established stock.

Edge Hall, Malpas. C. WOLLEY DOD.

Potting v. Planting of Arum Lilies.

THE system of growing arums in pots the year round finds favour with many who grow large quantities, and who require spathes at certain seasons, commencing as early as possible. For many years we planted out our arums, repotting them in the early autumn, and this system I have advised in these pages for the production of especially fine spathes. Needing a great many more plants than previously for decorative purposes, and these in large batches, we have for the past two years followed a different course of culture, growing arums always in pots, and treating them more like bulbs than otherwise. The season for resting arums will soon be at hand, so that my note will apply at this date. We usually rest our plants from May to early July, and this is an important part of their culture. The arums will have ceased to flower by the early part of May, and it is advisable to rest them at that season if early winter flowers are desired; by feeding and abundant supplies of moisture arums may be had in bloom at midsummer, but I think at that season, with a wealth of other flowers, they are unnecessary, while they are of great value at Christmas and Easter. It is to the production of winter spathes that my note refers.

From the end of April or early in May for about six weeks or two months our arums are placed in the open close together, much in the same way one would treat pelargoniums after flowering, and treated thus they lose many of the outside leaves. They are kept quite dry until potting time, and then the plants are shaken clear of the old soil and placed in pots; the largest roots will need eight-inch pots, as the growths are nearly as thick as one's wrist; there is the advantage in growing the plants singly that they are then most useful for decoration, and can be used to better advantage. The smaller plants go into smaller pots down to five-inch sizes. I need not dilate upon composts, as nothing new can be said, but it is well to pot firmly to obtain strong, sturdy foliage from the start, as thick, leathery leaves are as important as spathes for decoration. After repotting it is important to water carefully until new roots are plentiful; and the plants well repay cold frame shelter in rainy seasons, and growth is soon vigorous, and the plants should stand on a warm border or be exposed to full sunshine, so that by the middle of September they will be ready for housing. I have potted up much earlier than advised, after a much shorter rest, and plunged the pots up to their rims in an open border; this plan may with advantage be carried out by those who object to severe drying off. There is no difficulty in obtaining plenty of spathes for Christmas by the culture advised above, and this means much to many growers. From the time the plants are housed liquid manure may be given freely, as the pots will be full of roots, and the flower stems advancing.

Take now the case of plants put out in borders in May or June after flowering; of course it is necessary to divide if the plants are to occupy medium-sized pots when lifted, as they increase so rapidly that the smaller growth greatly robs the flowering plants. Potting up being done at the usual time, it is impossible to lift without breaking some roots, and there is thus a check; indeed, I have seen plants flag badly, for in some cases the ball of earth falls away from the roots, and for a time the plants are busy making new roots, and so flowering is retarded. I admit large individual spathes may be obtained from plants treated thus, and to many this may be an important point, but of course each one must study his own wants. On the score of general utility, I am strongly in favour of retaining the plants in pots all the year round, and drying off if large quantities of flowers are needed. There is also less labour needed for this system, and to many this is a consideration; the one potting up suffices, whereas quite as much time is taken in planting, and potting up has still to be done.

Syon Gardens. G. WYTHES.

MANDERSTON, DUNS.

THIS fine estate is the country seat of Sir James Miller, Bart., and is picturesquely situated about two miles from the small town of Duns, and the same distance from the station of Edrom, in Berwickshire, on the North British Railway. On the morning of my visit to the gardens of this establishment the walk from Duns was a most enjoyable one, along the well-protected and tree-lined road. Arriving at the lodge, Mr. Sharp, the gardener, was soon found, and he very kindly pointed out the objects of interest. As soon as one enters the gates the tidiness and general well-cared-for appearance of the place attracts notice: then, also, everything seems in the right place, and the good taste of the proprietor is well displayed.

The glasshouses are situated to the north of the mansion in the large, walled-in kitchen garden. They face south, and consist of a long range containing both plant and fruit houses. Entering by the stove end attention is drawn to a superb specimen of Polypodium subauriculatum suspended from the centre of a dome; this plant carries about a hundred fronds varying from twelve to fifteen feet in length, the stretch across the pinnæ being more than eighteen inches. Its receptacle is a wooden basket about two feet six inches in diameter, and it certainly is a wonderfully well-grown specimen. Other occupants of this house are useful palms, dracænas, and a fine lot of Anthurium Scherzerianum and its varieties, all bearing plenty of spathes. In the peach and nectarine house adjoining a good set was evident; the trees are grown upon the spur system now seldom adopted, and for some reasons scarcely to be commended. Figs covered the back wall, and a large number of pots of iris, ixias, Gladiolus The Bride, were being brought on for conservatory decorations. The vines in the next house were Muscats, and gave evidence of good bearing. The borders have lately been remade by Mr. Sharp. The conservatory, which forms the centre of the range, is a tall structure, the centre artistically planted upon a raised rockwork, palms, ferns and flowering plants giving it a very pleasing appearance. At one end is arranged a waterfall with a pool below, upon the surface of which the shadows of the surrounding plants are thrown. Against the roof are Cobæa scandens variegata, heliotrope, Plumbago capensis, and many other plants, while the side stages are filled with pots of liliums, cyclamen, richardias, azaleas, rhododendrons, &c., and the effect of these in conjunction with the greenery of the centre is very effective. Another peach-house gave promise of a good stock of fruit, the trees here being trained to the trellis both in the front and along the back wall.

The other end of the range contains an intermediate house. The centrepiece of this house is a huge example of Ficus elastica which is bearing fruit. Other occupants are gloxinias, Euphorbia jacquinæflora, ferns, &c., all making a very considerable display. Leaving this range of houses the kitchen garden is entered, and here everything was ready for cropping. Well-filled herbaceous borders edge the walks, and there was an abundance of crocuses, scillas, primulas, &c., in flower. A walk from the mansion bounded by a well-trimmed hedge of conifers leads through an arch and beaten wrought-iron gate into this garden, a sundial finding a place in the centre in close proximity to the range of houses. A large quantity of cut flowers are required here, and in the outer garden are frames of violets from which Mr. Sharp has been cutting nearly all the winter. Passing through some small pits filled with eucharis, crotons, and other plants requisite for the decoration of the house, besides a batch of Richardia Elliotiana, Vanda teres, and some phalænopsis, over a tank, we come to the orchid houses proper. These are span-roofed and built of teak which is plainly varnished. The warm house is filled principally with cypripediums, calanthes, and vandas, and of the first genus several good plants were in flower: C. Chamberlainianum, C. hirsutissimum, C. Exul, and Dendrobium densiflorum, were in evidence, as also a good plant of a Bromeliad—Tillandsia Regneli. In the well-filled cattleya house some good specimens of cattleyas and lælias were in flower, as also was a fine lot of Dendrobium nobile, D. Wardianum, and Cœlogyne cristata alba. A monster specimen of Epidendrum prismatocarpum, four feet or more through occupies a prominent position opposite the door. Of odontoglossums there were good examples in flower of O. Andersonianum, O. triumphans, O. Halli, O. crispum, &c. Wooden lath blinds are in use here and spoken very highly of.

In the garden are a few large oaks, elms, and limes, dotted about the north front, which is now being relevelled. Leading from the garden to the house is an ornamental piece of rockwork through the end of which runs a little stream. Here are many alpine and herbaceous plants and ferns which appear to enjoy their positions. To the south side of the house the ground slopes to a large sheet of water surrounded by a wood through which walks are cut. A bridge of stone spans a small stream and leads to one of the lodges, and along this road tree felling is being conducted to give space for good growth to those left. Although rather exposed to the winds from some directions, some good views are to be obtained of the surrounding districts from Manderston, and I was loth to leave this beautiful estate of Sir J. Miller.

H.

At Brooke House, Isle of Wight, the conservatory and greenhouses, under the capable management of Mr. W. Tribbick, contain some very interesting and well-grown plants. A large collection of Eucharis amazonica is in fine health. In the orchid department are some fine specimens of Dendrobium Paxtoni, and D. fimbriatum. The cypripediums in variety, promise a good show of bloom. The large collection of seedling amaryllis in a house adjoining the orchid department, is exceptionally fine; and elsewhere huge plants of cliveas, arums, and [illegible], are all gay with bloom, whilst there are two especially noteworthy plants, namely, Iris fimbriata, with eleven large spikes of bloom, and Iris Robinsoniana—the Wedding Flower. There are many other things of interest to the lovers of horticulture, says our Isle of Wight correspondent, at this charming garden.

VEGETABLES FOR EXHIBITION.

PARSNIP.

FOR some reason the parsnip (*Peucedanum sativum*) is not held in such high esteem as many other vegetables. One often hears the remark; "I like any kind of vegetables except parsnips." Nevertheless it is considered a most wholesome and nutritious article of food, and when well cooked it is much prized by many during the winter months. Anyone who owns a garden may cultivate them for ordinary use with very little trouble. It is a free-growing plant, is subject to few diseases or garden pests, and is extremely hardy. Indeed, after the roots have been subjected to severe frosts the flavour is much improved. A light sandy loam is unquestionably the favourite and most suitable soil for parsnips, but I have never seen a failure on any kind of land when properly treated. The ground should be deeply and thoroughly trenched during the autumn (certainly before Christmas), but not manured. A piece of ground previously occupied with celery is preferable to any other. The ground should be forked over and broken as fine as possible by the end of January or beginning of February, after which the seed should be sown at the very first opportunity, as in all stages the parsnip is perfectly hardy and a long season of growth is necessary. Drills should be drawn one and a half inches in depth and eighteen inches asunder. The seed should be sown thinly, pressed in, and levelled down finely with the wooden rake. Neat alleys should be thrown out on either side of the bed, and the whole should be finished off and left in a tidy manner. As soon as the seedlings are in the rough leaf thin them to one foot apart, and if the surface be stirred frequently nothing further will be required till growth is completed. Parsnips are much the best when left in the ground to be taken up as required, but it is as well to have a few in readiness in case of a long and severe spell of frost, or it will be found very difficult to lift them when the ground is hard. By the beginning of March the remainder should be lifted and stored under the north wall in sand or ashes, or the roots will commence to grow again, in which event they will be of little use.

Only a favoured few possessing an ideal soil for parsnips will be able to produce the fine clean-looking specimens often seen at our autumn shows, without a certain amount of care and trouble. But an enthusiastic exhibitor will not mind this, providing he can meet with success; and I am certain, from personal experience, that the very finest of roots may be grown on any soil if the cultivator will follow out the advice here given. As for beet-root and carrots holes must be bored, but these will require to be thoroughly made, and a depth of five feet will ensure this. Use a mixture of loam, road grit, and thoroughly decayed leaf soil in equal proportions, adding one peck of wood ashes to every barrow-load. The whole should be thoroughly mixed and passed through a quarter-inch sieve, and should be used as dry as possible. It should be pressed firmly into the holes, which must be twenty inches apart, and two feet from row to row. A small hole one and a half inches in depth should be made to receive the seed, in which four or five should be placed. These should at once be covered with fine road sand. Thin the seedlings to one at each station, and once a week, at least, the plants should be dusted over with soot, and the Dutch hoe used frequently. This is all that is required, and the cultivator may rest assured that when the time comes for lifting he will be rewarded with fine exhibition specimens from a small number of plants without digging over a great portion or possibly the whole of the permanent bed. In my opinion parsnips ought never to be shown before the end of August or beginning of September, but for October or November shows I consider them a most important dish in a collection of vegetables. The specimens should be of medium size, long and tapering from the top to the tip of the root without any sign of coarseness or canker, with the skin clean and white. Parsnips ought never to be dug up for exhibition till the day previous, or much of their freshness will be lost. They should be thoroughly soaked in cold water and carefully sponged but not rubbed, all the small rootlets should be removed with a knife and the leaves cut off to within three inches of the crown. Six is generally the number shown, and the whole should be arranged on a carpet of parsley in a pyramid, of course choosing a faultless specimen for the top. In close competition, however, each root will be examined, and rightly so; but nevertheless it is quite lawful for an exhibitor to present his produce to the judges and public in the best and most pleasing way he can, and arrangement, in my opinion, ought always to be taken into consideration. The Student, Hollow Crown, and Sutton's Tender and True, are all first-rate kinds for any purpose.

E. BECKETT.

Aldenham House Gardens.

WHITE TURKEYS.

THIS beautiful breed is probably more common in the south of Europe than elsewhere. At all our first-class shows a few are to be met with, but they lack the size of Bronze American and Cambridge Bronze. Those who breed them declare that the flesh is the finest of all in flavour, and I recently met a lady who breeds both bronze and white turkeys, and she declares that her husband, a well-known Midland baronet, will not have the former, and can at once distinguish [illegible] the table. This may be partly predilection, but he evidently knows the difference, and is very strong in his preference. A good white turkey is very handsome, and he has all the qualities of his race. Personally, I believe that the better quality is scarcely due so much to breed as to size, for the big birds are coarser in flesh, and lack the fine flavour which characterises small or medium-size turkeys. It would hardly do to apply this theory all round, for then we should have to alter many ideas and aims, but in poultry it is true. The biggest fowls are never the best, and frequently the largest eggs lack that flavour which is found in smaller ones. Weight, therefore, should only have its due influence.

T. B.

LANDSCAPE GARDENING.

Formation of Ground, and Levelling.

After a few general remarks on the importance of plan and system, Mr. Milner advised in his third lecture making a plan of the ground as it is. For this purpose the Ordnance Survey maps proved very helpful, and these might be divided into sections by lines, and so enlarged as to clearly indicate the physical characteristics and surface formation, artistic trees, buildings, rising and falling of the ground, the site of the house, terrace, pleasure grounds, stables, kitchen gardens, &c. The first two points insisted on by Mr. Milner after the choice of the site for house and gardens, were to husband the surface soil for future use; and to make a good solid approach, notably and preferably the back road, to form a useful road for the heavy cartage incidental to building. Plans should also be detailed showing the intended levels of drives and other parts. Numbered pegs should be put in at a minimum distance of one hundred feet apart, and the gradient line should be marked on the plan section to give the depth of cutting and filling, and the position of each peg. When the levels are settled, the drains for roads, walks, &c., can be laid, and if only surface water is to be carried, three-inch pipes are sufficient for two hundred yards, but for longer distances four-inch pipes are needed. On level roads or steep gradients, the gully holes should be twenty-five yards apart, but on a slight incline fifty yards apart. They should be more frequent on walks, as the gradients are often steeper and the gravel finer. The gratings for gully holes on roads should be nine inches, and on walks seven inches. Outlet pipes from gully holes should be placed at least six inches from the bottom to allow for deposit, which should be frequently removed. In forming roads and walks at least six inches of broken bricks, stones, coarse gravel or well-burnt ballast should be spread over the bottom; four inches will suffice for walks. Over this put a coating of stone that has been broken to pass through an inch riddle, and then of fine gravel three inches thick on drives, and two inches on walks, should be spread. A drive fourteen feet wide should have a fall of three inches from centre to sides, and a walk of six feet two inches fall.

Turf edging should rise one inch above the rolled surface of the road or walks. Turf, especially, that on slopes should have nine inches in depth of uniformly good soil under it to prevent scorching and irregularity of growth. As to the formation of lawns there is no better way than laying them with turfs three feet long and one foot wide and one inch deep, or sowing them with forty-five pounds of mixed grass seeds per acre. It speaks volumes for the soundness of the late Mr. Robert Thompson's receipt in his "Gardeners' Assistant" to find this still valued by Mr. Milner. Certain general principles were referred to as to curved lines whether of surface, walks, or roads, and the general rule laid down that the curves should be set out with broad sweeping lines the chord of which should be so great that each sweep should be hidden from the succeeding bend. A multiplication of meaningless curves on walks should be avoided, as should be the creation of the wriggling serpentine lines so often seen in little gardens.

Planting.

Planting, in landscape gardening, has a wide and special meaning. It includes far more than preparing the soil for the plants, or placing the plants skilfully in the ground. Mr. Milner said that as a skeleton must be clothed with living flesh to be a thing of beauty, so the undulations or main features of the ground need to be covered by verdant grass, with its delicious expression of restful quietude; and thereon Nature lavishes her infinite variety in form, height, colour, and contrast. The gradations of the sky line, the fine irregularities of line where the lower verge of foliage touches lawn or grass, the emphasis of sunshine and of shadow, have to be considered as well as trees and plants. These form our landscape, and practically these are the chief points to be settled before we plant. One place needs shelters, a second concealment, a third opening to reveal a distant prospect. Rising ground may apparently be raised, if we cover it with wood, but the trees should be tallest as they reach the summit; the outlines of groups in a park should not be regular, nor in a succession of easy sweeps, or form a serpentine line. They should have strong prominences marked by detached trees that stand out boldly in the group, and they should present deep recesses. In plantations near the eye lights and shadows are more apparent than on distant groups, and the effects are stronger, therefore dark foliage planted in a near recess makes it appear deeper still. White foliage or blossoms seem to be nearer the spectator than they really are. Objects become fainter in effect as they retire from the eye, so detached clumps, or a single tree of lighter green, will therefore seem to be further off than an equidistant plant of darker hue. A regulated gradation of one tint to another will apparently add to the length of a continuous patch, according as the gradation commences with foliage of light or dark green. When a long continuous line of boundary or other planting cannot well be broken, for sheltering or other reasons, a pleasing variation may be given by placing light green plants of graduated tints at certain positions in its course, as the effect is to give the idea of distance at those points; this idea of expanse will be still more promoted if the sky line of the tree tops is lowered with a gentle curve, lowest where there is the lightest shade of green.

Among the dark foliaged trees may be named the oak, chestnut, beech, elm, Austrian pine, spruce, cedar of Lebanon, hemlock, fir, yew, and holly. Among the lighter greens—Plane, birch, ash, acacia, lime, poplar, willow. laburnum, larch, Abies concolor, Pinus insignis, Abies Douglasi, and Cedrus Deodara. Among red-greens are varieties of maples, the American oak, and purple beech. Among white-greens—Buckthorns and poplars. Mr. Milner at the close of his lecture, illustrated the grouping of trees in relation to their character, and colour, as well as the furnishing of villa gardens, &c., with illustrations on the black board. He also briefly referred to the effect of judicious pruning in relation to the planting and furnishing of landscapes, noticing the Japanese mode of dwarfing plants—keeping a century-old tree down to three inches—and some spruces that he had seen in East Anglia a few feet high and a hundred years old. Some details of his method of transplanting large trees, with lists of trees and shrubs for different soils and sites, concluded an informing lecture. All ground for planting should be trenched at least two feet deep, and in making new gardens all good earth from foundations of buildings, roads, &c., should be stored for forming raised banks, or deepening surface tilths.

With a staff of thirty men as many as twenty trees whose stems average one foot in diameter at the ground level, with a height of thirty to forty feet, have been safely removed to new positions at an average distance of one hundred yards in one day. The trees were prepared on the previous day. Those most suitable for removal are horse chestnuts, sycamores, maples, limes, beeches, service trees, and mountain ash. Open a trench five or six feet distance from the stem, severing the larger roots and winding the smaller round the ball of the tree. At a depth of three or four feet dig nearer the stem, shaping the ball like an inverted cone, leaving a base of earth two feet in diameter under the stem. Bind ball and roots firmly round with matting, and then place thick planks on each side of the central support. Pass good ropes two-thirds of the way up the stem of the tree and pull one of these in the direction of the main plank, and draw the tree over to one side. Place two or three six-foot planks under. Pull the tree over on the opposite direction and repeat the operation. The tree has thus a platform of planking resting on the two bottom ones, or sliding planks on wheels, the cross planks forming a carriage slide. Place the sliding planks in the line to be traversed, and also at the easiest way out. The cross planks should be bound together and a piece of matting placed over the stem. Pass a strong rope over the stem and let it cross the ball diagonally. Carry each end with a half-hitch over the stage of cross planks, and deliver an end of the rope to men on each side of the tree. These, ten or twenty in number, take the two ends of the rope and are ready to start. Planks are, meanwhile, laid from those under the tree to the required distance, care being taken that each succeeding plank end is placed a distance of six inches under the preceding one. These planks are then wetted or smeared with clay if the way is uphill. Two men hold guide ropes to steady the tree, and the others drag the tree to its place. Arrived there, remove the ropes, planks, and matting; place the roots on the site in about two feet of good soil, then ram the other soil firmly round the roots. For smaller trees, not exceeding six inches in diameter and weighing about a ton, a small sledge is more convenient. If many roots have been removed the leaf area of the tree should be reduced about one-fourth.

Mr. Milner concluded his lecture on planting with lists of plants for different soils and aspects of which it may be useful to name a few in each division. For shady places or undergrowth—Aucubas, berberis, yew, evergreen privet, laurel, holly, St. John's Wort, vincas, abies, blackthorns, and hornbeam. Chalky soils—Elder, ribes, thorns, beech, box, cotoneasters, yew, poplars, St. John's Wort, Prunus Pissardi, guelder rose, and periwinkle. Peaty soils—Rhododendrons, azaleas, andromedas, heaths, willows, birch, hemlock, spruce, white cedar, and kalmias. Exposed situations or near the sea—Pinus pinaster, P. austriaca, P. maritima, Abies cephalonica, poplars, sycamore, wych elm, thujopsis, cupressus, juniper, euonymus, white spanish and crimson broom. Near towns or in smoky districts—Austrian pinus, service trees, birch, almond, crabs, planes, chestnuts, willows, berberis, deutzias, laurestinus, evergreen laurel, privet, weigela, euonymus, hollies, and lilacs of sorts.

D. T. F.

THE PEACH.

The cultivated peach is a tree that will not successfully withstand either excessive heat or cold; Spain, Italy, Greece, Persia, and countries enjoying similar climates to these seem best suited for its culture. It will not thrive in a torrid climate owing to its requirement of an annual rest; nor in a very cold climate, for here the soil is too cold for the roots in winter, unless the peach is grafted on to some hardier stock such as the plum or almond. The almond is the favourite stock with most gardeners in this country. Peaches requires at least the protection of a wall in England, and some consider a broad coping is also necessary, but this all depends on the situation. The trees flower rather early, generally at the end of March, but blossoms will stand a large amount of cold so long as frost is kept from them, and they are dry; but excessive heat on the other hand proves very injurious. Seedlings are readily produced, but budding and grafting are the general means employed for propagation. We must, however, have seedlings ere we have new varieties, and seedlings also provide stocks, indeed, a stone sown in the autumn will produce a shoot fit for budding in the following autumn with proper care. Peaches do very well on their own roots indoors; but unless the climate and situation are very favourable, when grown outdoors, they, in a few seasons, become weak, the leaves become tinged with yellow, and the tree is soon useless, probably because the soil has been too wet or cold for the tender roots of the peach, whereas those of the almond or plum being more hardy would stand the unfavourable conditions better.

A south or a south-west aspect, with a well drained border, suits peaches, but if the subsoil is wet and the border insufficiently drained, the tree will take up more moisture than is needful, and the result will be rank growth that will fail to ripen properly. On the other hand it should not be very dry and sandy, or during the hot weather the tree will suffer from drought unless a large amount of labour is expended in watering. The trees not only require moisture for their growth, but also sufficient to replace that given off by the leaves during the time of bright sunshine or dry winds. If the roots are not supplied with sufficient moisture to meet these wants the tree must consequently suffer, for so long as the roots contain any moisture the leaves will draw from them until eventually exhaustion and shrivelling occur. In hot dry weather there is also that little pest red spider to be guarded against, and it can only be kept in check by a regular application of water on both sides of the foliage every day. Peaches will not support a good crop of fruit if in a poor and sandy soil, nor will they do so in a heavy clay; the most suitable mixture for a peach border is good turfy loam mixed with some dry cow manure and a good supply of lime siftings. Such a compost can be afterwards enriched by a top dressing of bone meal. It is an excellent plan to keep the surface of the border covered with a layer of stable litter, for this keeps out the frost in winter and prevents excessive heat from drying up the soil in summer. The trees are very apt to gum, especially if they grow with excessive vigour during the summer, so as to necessitate a hard pruning in the following spring; this can, of course, be avoided by careful summer pruning.

Earwigs are very destructive to the fruits, and are best trapped by placing pieces of broad-bean stalk about the tree and emptying them into some hot water every morning. Fruit should be fully exposed to the sun, especially as they near the ripening stage. When gathering the fruit it should be taken in the middle of the hand with the soft part of the fingers and thumb well behind it. In this way the most delicate fruit may be pulled, with a due amount of care, without risk of injury, as when ripe it readily parts from the stem.

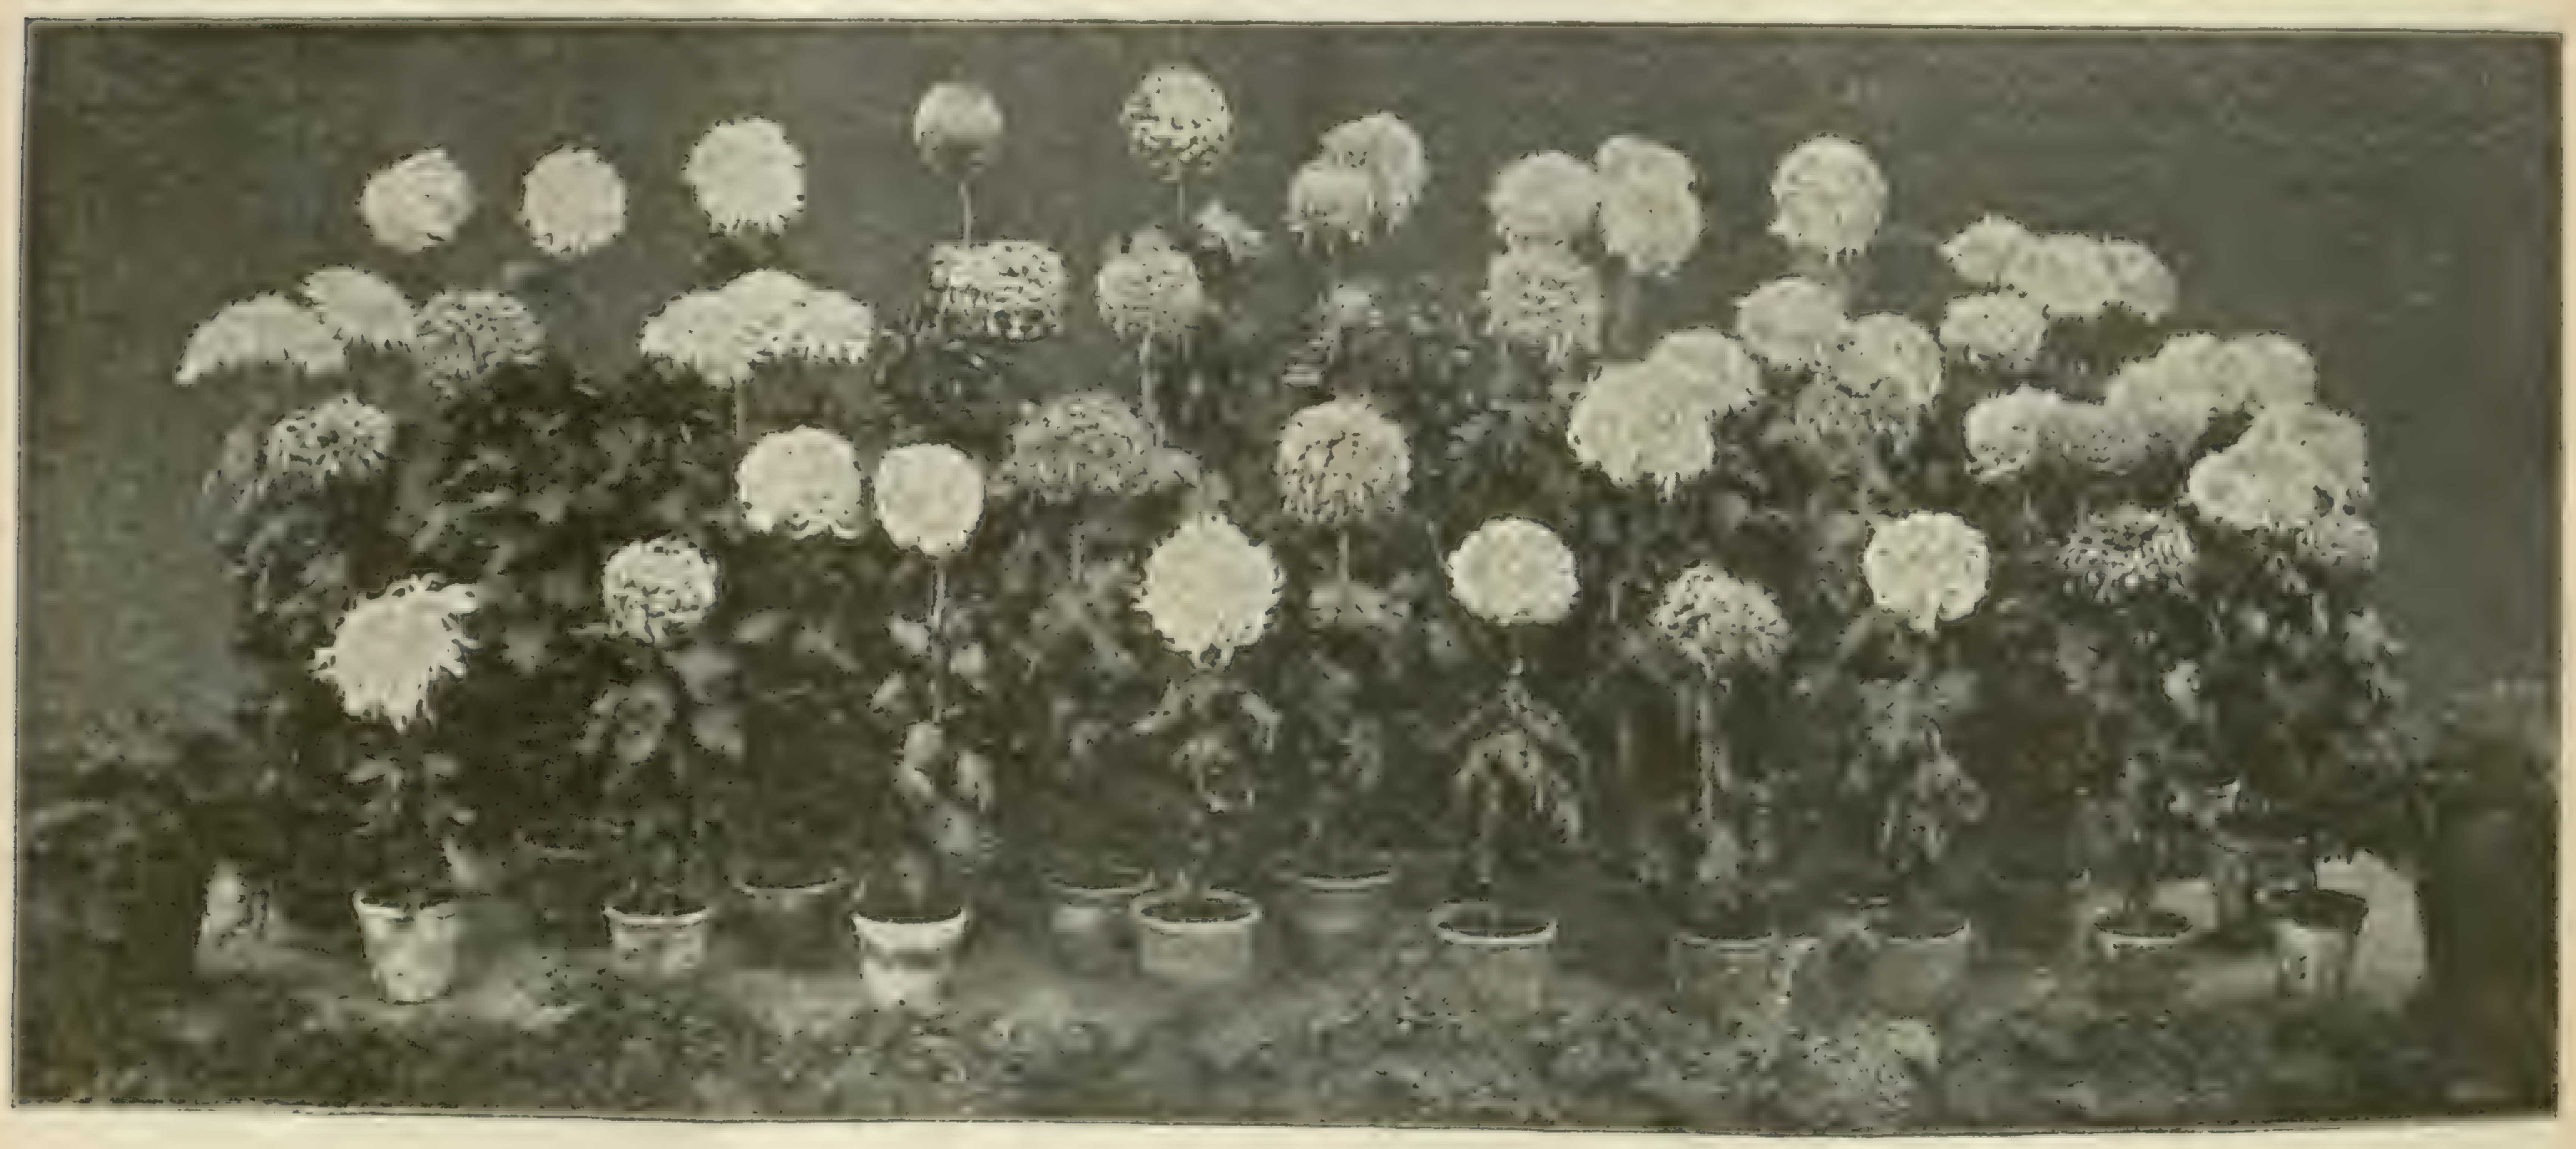
DWARFED CHRYSANTHEMUMS.

As the remarks in the Gardeners' Magazine in November last, descriptive of the plants then in bloom here, appear to have created some interest among cultivators of the Autumn Queen, I am induced to refer to the subject. For grouping, either for competition or for home decoration in conservatories, rooms, &c., this system of late cuttings is invaluable, and I feel certain there are many gardeners who, if they once tried it, would be more than pleased with the result. I may at once say I do not claim it to be a new system, for it has been practised in France, and discussion on the same was held in Lyons in 1896. With the remark not long since made that there was not much in the system I entirely agree, but to how many other methods might not this apply with equal force?

It is about four years since I first grew a few dozen chrysanthemums from late-struck cuttings, and was so pleased with the result that each year since I have increased the number of plants grown, and also tried many more varieties. For some years previous I had practised what is known as the cutting-down system, and to me this always seemed a most barbarous one. Cuttings were struck in December and plants grown on until the beginning of June; then the plants were cut down and labour was thrown away; then when the time for blooming came *how jew* produced blooms fit for cutting for exhibition as such; but by striking late some of the finest blooms I have ever seen have been produced, and during the past four years many have been exhibited on winning stands in strong competition, a result I have never seen from cut-down plants. Should anyone want to grow exhibition blooms alone, not caring for grouping, &c., I do not recommend them to try this system alone, but, as before stated, when both are required, I know of no system to equal this, for by it you can have plants in forty-eight and thirty-two sized pots, carrying from one to three blooms, the stems ranging in height from one to three feet, and with foliage to the rim of pot; such plants are invaluable.



DWARFED CHRYSANTHEMUMS AT FOXBURY.

I will as briefly as possible explain my practice, also give a list of varieties I have found to do best under it. There is another advantage however, I might just mention, that is, late-struck plants seldom throw up suckers until late in the autumn, and generally these are much stronger than from older plants; as every cultivator knows, many varieties begin to throw up suckers early in August, and these having to be continually taken off, it happens that when the time comes for taking cuttings, these are often drawn and weak. Then also you can store many more six-inch pots in a given space than the ordinary nine or ten inch ones, and this is a consideration where a large collection is grown. As many plants and varieties as I think I shall require are kept as cool and hardy as possible, giving sufficient protection in severe weather to keep them alive; this last season many have been standing at the foot of a wall, out of doors, as we have had so little frost, and they have needed scarcely any protection at any time. Had the weather been very severe, I would have plunged the pots in ashes, and covered the tops with a mat or litter. About May 18 or 20 we begin to take cuttings, putting each cutting singly in a thumb pot; the pots are then placed in a frame on a spent hotbed, where there is a very slight bottom heat. In about eight or ten days some will be rooted, when they are at once removed to a cold frame, and gradually hardened off; if left only two days after rooted they become drawn, therefore it is necessary to look over them every day until all are rooted. As soon as the plants are ready they are shifted into sixty-sized pots, and stood in an open position, and when these pots are full of roots we give a shift into forty-eight or thirty-two sized pots, according to variety and strength of the plant. During the remainder of the summer they require similar treatment to that accorded other chrysanthemums, care being taken not to let them become dry, for being in such small pots they require feeding, little and often being the safest plan. Some varieties will show a bud shortly after the cuttings are rooted. Such must be pinched off, and as the plants break from one to three shoots should be left as the cultivator deems fit. Of course when one shoot only is left, the bloom will be finer than if three are left, some varieties, viz., Souvenir de Petite Amie, Louise, Phœbus, W. Trelase, W. H. Lincoln, Boule de Or (Calvat's), Elsie Teichman, Viviand Morel, C. Davies, and several others will give good blooms, and make pretty plants when three shoots are left. Some varieties will grow from ten inches to two feet before showing a bud, and if this shows after August 1 it should be secured, as it is by these plants extra fine blooms are produced.

The following varieties I have found do well under this system of culture: Japanese—Col. Smith, one bloom, generally grows two feet high; Vivand Morel, Lady Hanham, and C. Davis, one to three blooms; Emily Silsbury, one to three; Lady Byron, Melano, Matthew Hodgson, Mr. A. G. Hubbuck, Oceana, W. Wright, Woods Pit, Mr. Gus Henry, Modesto, Sunstone, Hairy Wonder, C. Shrimpton, Duke of York, and E. Molyneux, one bloom each; Golden Gate, Etoile de Lyon, and John Shrimpton, one to three; H. L. Sunderbruck, Kentish White, Lady Randolph, Madame Carnot, Golden ditto, Mutual Friend, Miss E. Addison, and Miss M. Blenkiron, one each; Mrs. C. E. Shea, this variety when half expanded looked most promising, and some blooms were over a foot across, but before the centre developed the outer petals were past, therefore I shall not again try more than one or two plants of this variety. Mrs. C. H. Payne, very good, one bloom; Mrs. H. F. Druet is very pretty and distinct, one bloom; M. Chenon de Leche, very fine and dwarf, one bloom; Niveus, very good, one; Phœbus, one to three blooms; Pride of Madford, one; Reine d'Angleterre, one; Lady E. Saunders, very good, one; and Australian Gold, one. The foregoing have all done well. I have tried many other sorts, and some have been equal to the above, but others not so good; these named may be relied on. There are two other varieties, viz., Mrs. H. Weeks and Mrs. C. Blick, when grown on single stem, with their fine large foliage drooping over the pots, and monster blooms above, have only to be seen to be admired, but there is this difference with these two: cuttings should be put in by the end of March; confine them to one shoot, and taking the first bud that shows, as for the best bloom of Mrs. H. Weeks I had the bud was taken July 27. Others taken August 1 and later were not so good. Mrs. Blick may be taken a little later, but I like to obtain buds of this before August 20. Plants of these two varieties treated as above produced some of the finest blooms I saw last season.

The following incurved varieties I have found do well, but I restrict them to one bloom, with the exception of Mrs. Rundle and her sports, on which I have three: Sir T. Lawrence, Duchess of Fife, D. B. Crane, C. H. Curtis, the best of all grown this way, Bonnie Dundee, C. B. Whitnall, R. Petfield, G. Haigh, Mrs. R. C. Kingston, Harold Wells, Lyne jun., Mr. J. Murray, M. P. Martignac, Ernest Cannell, Major Bonnafon, Baron Hirsch, Mrs. G. Rundle, Mr. G. Glenny, and Mrs. Dixon. The last three are very pretty, producing three good blooms in a six-inch pot, and never growing more than three feet.

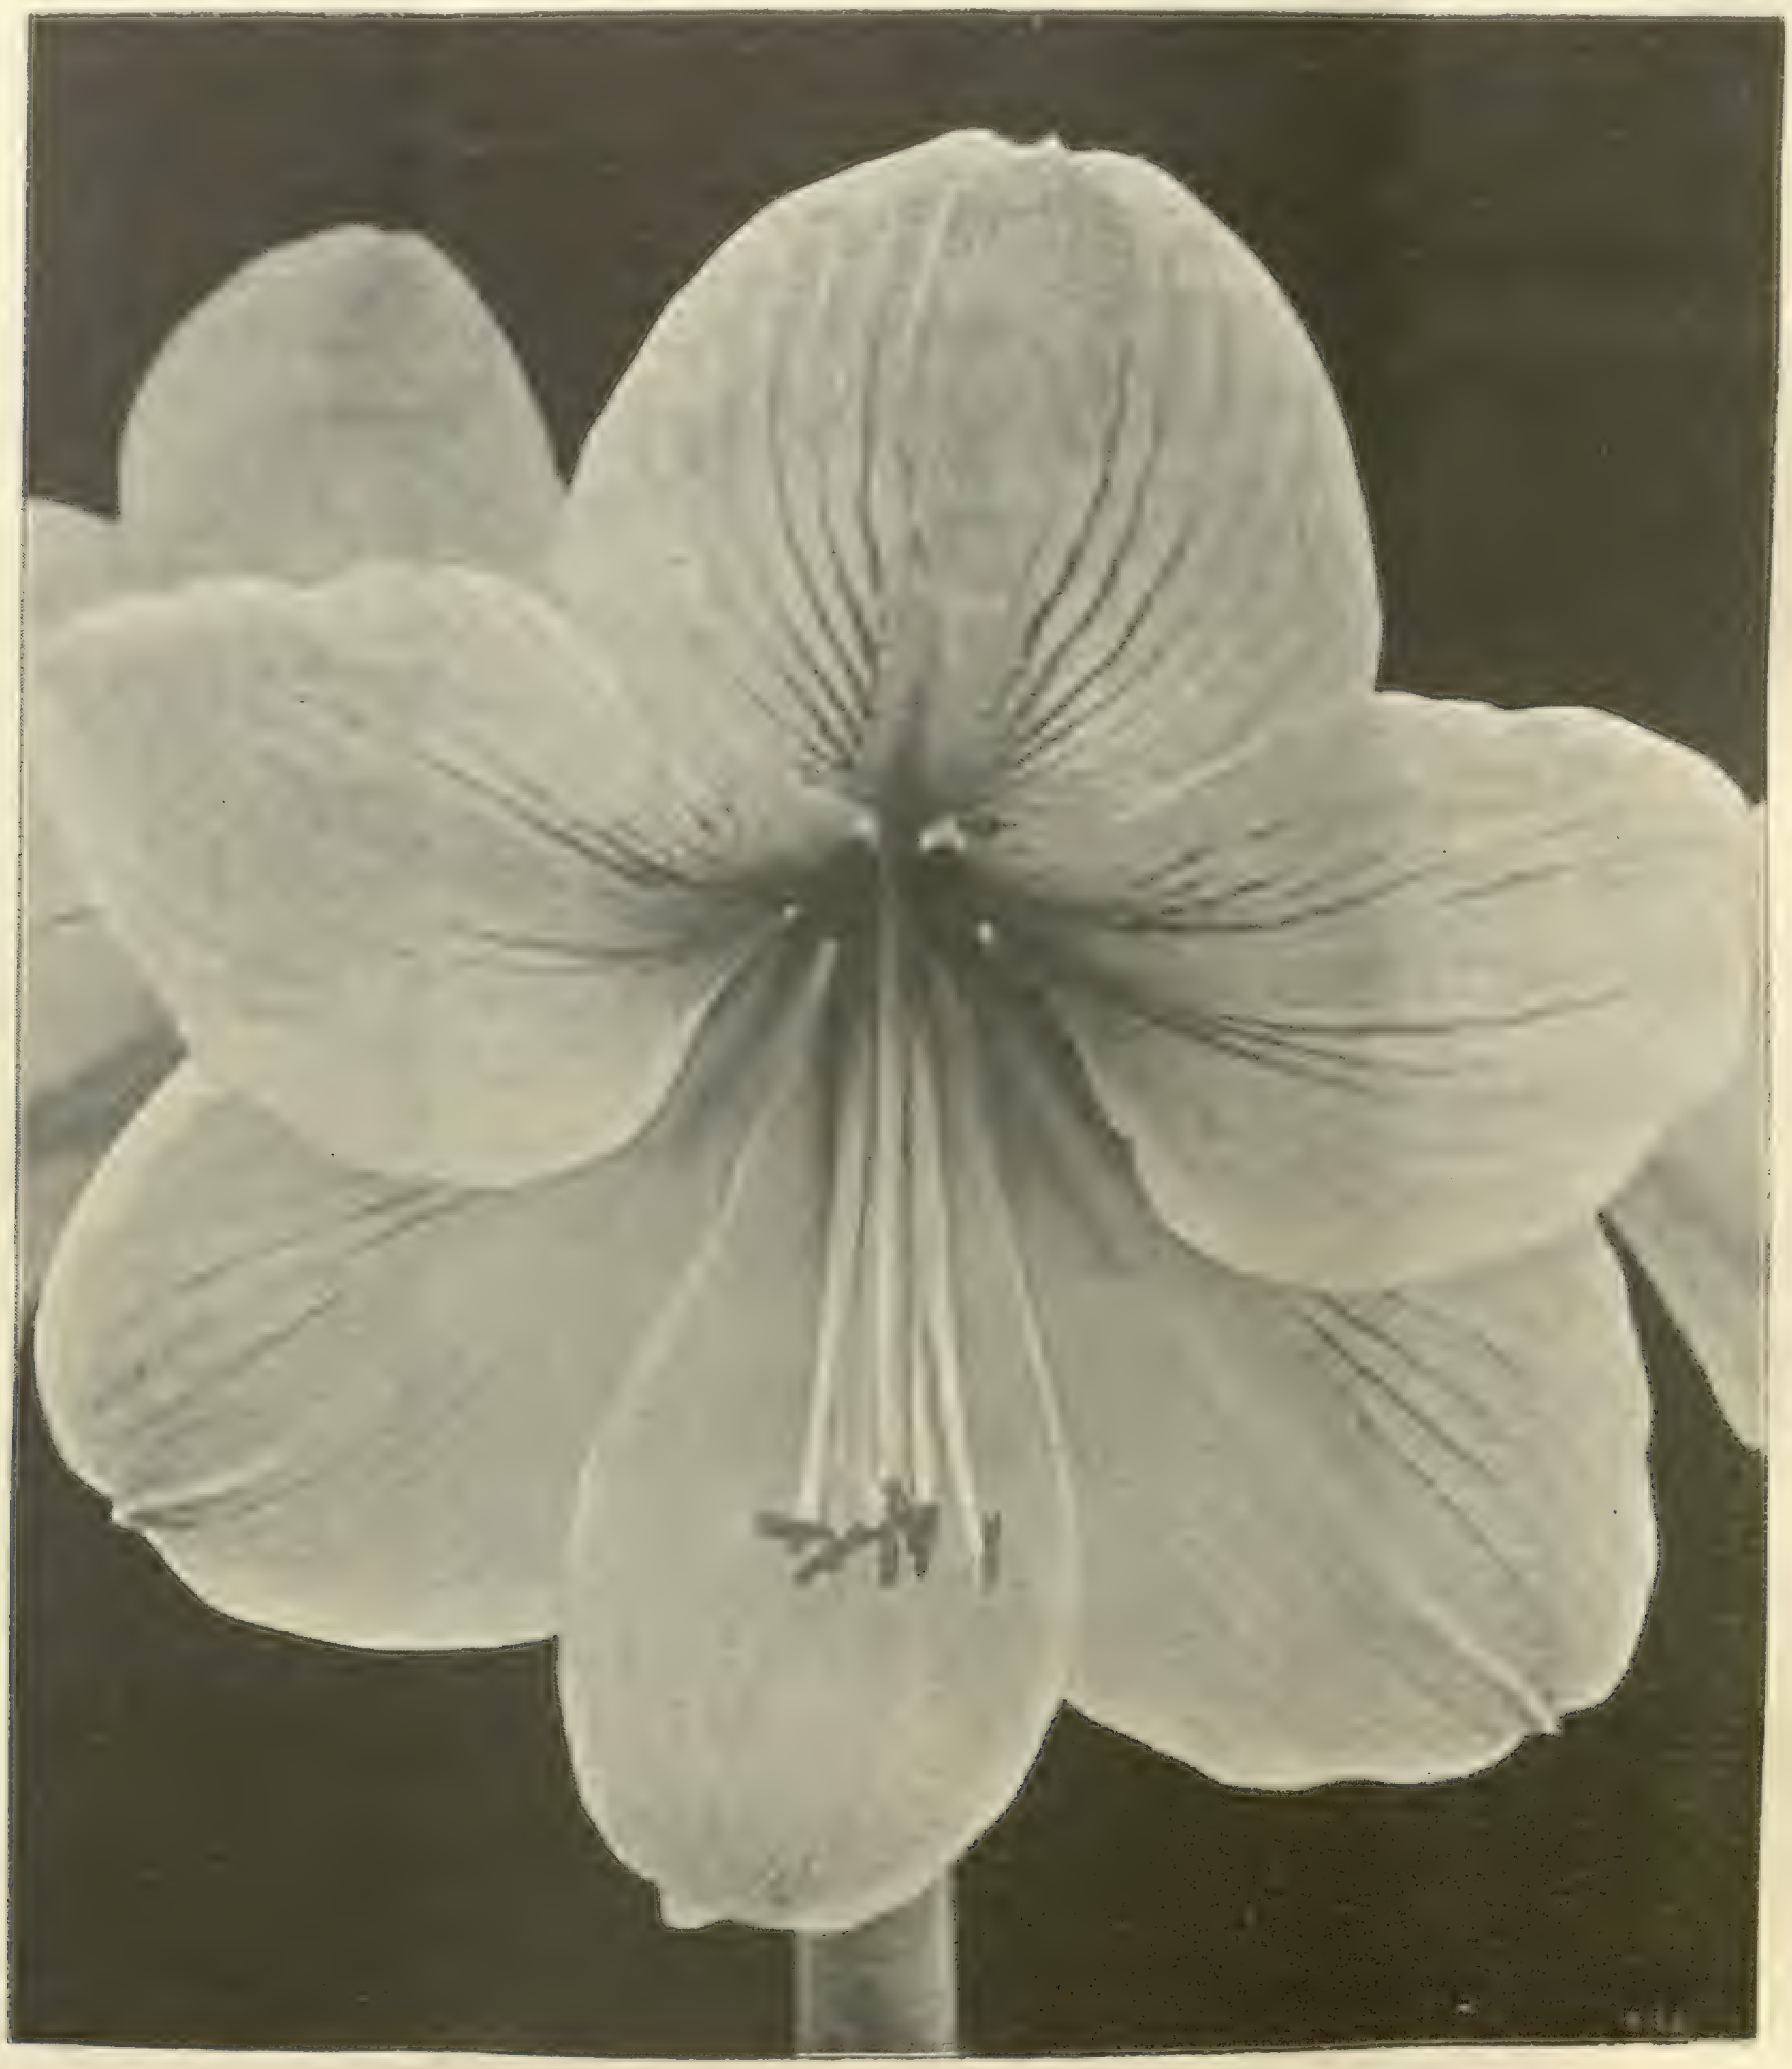
J. Lyne.

Foxbury Gardens.

Farm Labour in Queensland.—We learn from the Emigrants' Information Office, Westminster, that in the agricultural districts of Queensland there is a demand for good ploughmen and farm hands. The sugar industry is in a prosperous condition, and there are excellent openings for farmers with a little capital, after they have acquired some experience of the country. Miners and mechanics are in demand at some other of the Australian colonies, and in Canada.

HIPPEASTRUM MRS. GEORGE GORDON.

Among the seedling hippeastrums flowering for the first time in 1897 at the Chelsea nursery of Messrs. J. Veitch and Sons there were a number of particularly beautiful forms, especially attractive by reason of the great breadth of their segments, the rounded outline of the flower, purity of the white ground colour, and general robustness. At the head of these fine light varieties came the variety now illustrated, and named Mrs. George Gordon. With the exception of a few crimson and rosy crimson veins and pencillings, the variety is wholly white, and so it follows closely the almost pure white Iphis. A bloom of Mrs. George Gordon measures seven and a half inches across, and three or four flowers are produced on a spike. Seedlings from this variety have been obtained already, so that the extreme beauty of form will, it is hoped, be perpetuated. As stated in our report of the Chelsea exhibition, hippeastrum Mrs. George Gordon is again this year one of the very finest of the light varieties.



HIPPEASTRUM MRS. GEORGE GORDON. (Flowers white and crimson.)

GOOD STRAWBERRIES FOR FORCING.

A short time ago, in these columns I saw a solitary note condemning Strawberry Royal Sovereign, and thought the writer a bold man. We have just gathered one crop of strawberries of this variety; three hundred plants were started at the end of December for hard forcing, and I am more pleased with the behaviour of Royal Sovereign than in previous years, as few plants have failed. The percentage of fruit per per plant has been larger than from other varieties. For many years we relied upon Vicomtesse Hericart de Thury for first supplies, and, as regards flavour, it has few equals; but in our sunless locality we always experienced a difficulty in persuading the flower trusses to extend beyond the leaves, and another point was the smallness of the fruit. Royal Sovereign produces flower-trusses so freely that it needs support even in February, and the fruits are all one can desire, equal in size to ordinary summer fruits from open beds, while the quality is really excellent for strawberries at the season named. Quality in forced fruits of any kind is a debateable point, but in March a strawberry that is firm, large, and good, even if it is a little acid, cannot be much condemned.

Taking an interest in these fruits I recently made it my business to interview one of our largest Covent Garden salesmen as to the strawberries sent him, and I found Royal Sovereigns a long way ahead of all others, and I was not at all surprised considesing it produces so few small fruits, carries well, and is of a bright, fresh colour. This variety, being grown so readily, has, however, brought down the prices. From the private grower's point of view I have found Royal Sovereign a grand variety for forcing, and it can be grown with the certainty of a crop. At the present moment we have, in various stages, close on two thousand pot plants of this variety, and it is a great favourite for large gathering in the open early in the season; probably we have close upon five thousand fruiting plants this season: this shows it is appreciated. I know of no other variety so reliable for first supplies if grown well.

Another really excellent forcing strawberry is La Grosse Sucree. This produces beautiful fruits, and what is better, forces freely; for many years this was our March and April strawberry, but this year we gave Royal Sovereign a trial and we were not disappointed. La Grosse Sucree in the open is not so vigorous in our soil as the newer variety, but for forcing we still grow it by the thousand, and like it for its fine setting property, splendid dark-red points, its quality and shape. For later supplies, so far, we have found it difficult to beat the well-known but good President. I am aware it has a tendency to mildew, but taken in time mildew is easily kept down; and this variety is of first-rate quality, packs well, and will hang for days in a cool, dry house without loss of flavour. For cropping in the open as a midseason variety it is one of the best. For many years we grew several varieties for forcing from February to June, but the above kinds have proved so reliable that we grow them only.

G. Wythes.

WORK FOR THE WEEK.

COOL ORCHIDS.

CŒLOGYNE cristata and its varieties are usuallv grown in the intermediate house, but amateurs who have not this accommodation will find this beautiful orchid grow satisfactorily under cool treatment; no collection, however small, is complete without it, for it is certainly one of the best winter-flowering orchids we have, and deserves every care and attention that can be possibly given. Small plants, when grown in baskets suspended from the roof, and well established, flower freely, but old established clumps when properly treated flower much more abundantly; these specimens should not be disturbed unless they have overgrown their receptacles, or it is desirable to increase the stock, as it thrives best when a mass of bulbs. Plants that are in a good healthy condition soon overgrow the receptacles in which they are cultivated, and having no material to root in the bulbs soon decrease in size, and therefore cannot produce strong flower spikes; in such cases the leading pieces around the plants may be cut off and made up into small compact specimens. It is now a good time to attend to such matters, if necessary. Pans of a suitable size should be filled to within two inches of the rim with clean drainage, over which place a good layer of rough moss; the compost should consist of lumpy peat and fresh moss, with a little fibrous yellow loam and finely-broken crocks intermixed. After repotting, cœlogynes require careful treatment, as any root disturbance usually causes the pseudo-bulbs to shrivel slightly; do not deluge the plants with water in order to plump up the bulbs, but stand them in a shady position, syringe overhead, and damp between the pots. When well rooted in the compost and growing freely, an abundant supply of water should be given and more light afforded without exposure to bright sunshine; they will then make strong healthy plants.

Oncidiums are favourites with most lovers of orchids, and of the cool species there are many of remarkable beauty and distinctness. Such species as O. crispum, O. curtum, O. cuculatum, O. prætextum, O. candidium, O. Marshallianum, O. Gardnerianum, O. Phalænopsis, O. Forbsei, O. concolor, &c., may be grown in company with the masdevallias or odontoglossums, and are best grown suspended from the roof in well-drained pans or baskets; only a thin layer of material should be used, as these plants dislike a large quantity of moisture-holding material about the roots. They require a liberal supply of water during the growing season, but after growth is completed only sufficient should be given to keep the bulbs plump and firm. Numerous importations of these species takes place at the present season, and when the plants reach the grower they are sometimes very much shrivelled owing to their long journey, but it is not a good practice to pot these up in such a condition. After they have been thoroughly cleaned and all decayed roots and bulbs cut away, they should be laid on the stage in the cool-house, over a thin layer of sphagnum, occasionally spraying them over on fine days; this will help to plump up the bulb, and new growths will push out, from which roots will soon appear. When this stage is reached potting up in suitable sized pans, in a compost of equal parts of peat and moss, may be performed; keep the atmosphere nice and moist around them and water carefully.

We often have very changeable weather during this month, and constant watchfulness is necessary; shading should be used freely, and air should be given in accordance with the outside conditions. A regular supply of moisture must now be kept up by thoroughly damping the paths, stages, and other surfaces at least two or three times daily; very little heat from the hot-water pipes will now be wanted unless the nights be cold. as is sometimes the case. when a little should be given in order that ventilation may be maintained, for cool orchids do not like a stagnant atmosphere.—E. SHILL, *New Hall Hey Gardens.*

STOVE PLANTS.

DURING April is a suitable time for propagating Reinwardtia tetragyna, one of our most showy winter-flowering intermediate-house plants; its flowers are yellow, about an inch in diameter, and though the individual flowers do not last long they open in such quick succession that the plants are literally covered with bright yellow for several weeks during the dull winter months Though the old plants may be cut back and grown on a second season, by far the best results are obtained from those raised by cuttings inserted in April. For cuttings choose the strongest points of the old plants, insert singly in thumb pots of sandy soil and plunge in the propagating case; when rooted put into three-and-a-half-inch pots, and again later into six-inch pots, in which they will flower. A suitable compost consists of two parts loam, one part peat, with leafsoil, sand, and a little well-decayed manure, pinch frequently during growth to produce compact specimens, and as they are subject to red spider the syringe must be frequently employed to keep it in check. During the latter part of July and through August the plants may be grown in a cold frame where they will receive plenty of air and sunshine to ripen their shoots. Tops of dræcenas, crotons, and dieffenbachias which were notched and mossed a few weeks ago may be cut away, if the roots are showing, and potted into five or six inch pots, being careful not to break the rootlets during the process; when potted plunge in slight bottom heat and keep well shaded until established. Eyes of dræcenas inserted in pans early in the year will now have made growths of from three to four inches high; instead of potting these with the old piece of stem attached, cut the growth away with a sharp knife and insert in a thumb pot, as by this method better plants are obtained. Prick off gloxinias, Cyperus alternifolius, Isolepis gracilis, gomphrenas, Saintpaulia ionantha, Didymocarpus malayanus, and other subjects before they become drawn in the seed pots, using light sandy soil containing plenty of leafsoil, as there is nothing better than the latter to encourage root action in small seedlings. Asclepias curassavica, though seldom seen, is worthy of extended cultivation; it is generally afforded greenhouse treatment, but better results will be obtained if it is grown in an intermediate or stove house. We have a large batch which have been flowering for many weeks; they have had a night temperature of 60 degrees all winter, with 5 degrees rise by day. If seed is sown or cuttings inserted at the present time they will produce useful plants for the coming winter; six-inch pots are a suitable size to flower them in, the compost consisting of loam, leafsoil, well-decayed manure and sand.

Climbers in the stove will require frequent attention in the matter of regulating and tying-in the growths, as it is of importance that these should not become too thick on the roof and unduly shade the plants below; attend to this matter at least once weekly, cutting out superfluous shoots, and in the case of stephanotis, clerodendrons, dipladenias, and aristolochias give timely attention to tying before the shoots twine themselves round the wires. Aristolochia gigas, though not exactly a desirable plant to grow on account of the disagreeable odour of its flowers, is still sometimes grown owing to its gigantic size and quaint form. If allowed to grow at will it is apt to drop its flowers, and to obviate this each shoot should be pinched when it shows a flower bud, and thus a crop of flowers will be obtained. Cuttings of Scutellaria mocciniana, if not already put in, should be inserted at once in sandy loam. All cuttings as they fill their pots with roots should be potted on before they suffer, or they may receive a check from which they may never thoroughly recover. Attend closely to shading, especially when a bright day follows two or three dull ones. Afford air moderately on hot sunny days, avoiding draughts. Close early to run the temperature up to 85 or 90 degrees, at the same time giving the plants a good syringing and damping well among the pots, on paths and walls. The night temperature of the stove to be maintained at 70 to 75 degrees by fire heat; intermediate house, 60 degrees by night and 65 by day.—J. TUNNINGTON, *Ripley Castle Gardens.*

KITCHEN GARDEN.

PEAS for main crop may now be sown, choosing such varieties as Danby Stratagem, Veitch's Main Crop, Invincible, or Superabundant, any and all of which are first-class kinds. In some districts where the soil is light and poor, and where the rainfall during the summer months is slight, special care must be taken in the cultivation of this crop. The ground should have been dug in the autumn that the soil may have settled down to conserve the moisture. In sowing make the drills rather deeper now than in the earlier part of the year, and plant rather than sow the seeds. Where tall growing kinds are grown, these should be allowed a greater space than the dwarf or medium ones, as more moisture will be needed for their support. There are from eight hundred to a thousand peas in a pint of seed, therefore if a double line be planted, placing the seeds about three inches apart, half a pint will be sufficient to plant a row twenty yards long. As soon as the early varieties commence flowering give them a slight dressing of sulphate of ammonia, and if the weather be dry a gentle sprinkling of water to dissolve it. Make a sowing of Dwarf French Beans in a warm sheltered border where the plants can be afforded protection in case of frost. There are so many good varieties to chose from that it is difficult to say which is best, but as most gardeners have their own particular fancies I must leave them to choose. Prolific Negro is a favourite here for a first sowing. Another sowing should also be made of broad beans, such as Masterpiece Longpod or Green Giant. Carrots in some gardens form an important crop. On light hot gravelly soil they are difficult to grow unless special prepartions are made for them, but on some soils fine clean roots may be produced without any difficulty. It is far preferable to make small sowings at intervals of three weeks or so till the first week in June, than to sow a lot thus early in the season, as the roots under good cultivation become coarse and overgrown, necessitating lifting too early in the autumn. In all private gardens it should be the aim to have tender succulent roots instead of those large specimens so often seen.

Brussels sprouts, savoys, borecole, and some of the early brocccli should be sown where not already done, but it is far better to defer the sowing of these for a few days than to have the plants overcrowded in the seed beds. Dwarf stocky plants always give the finest results, so for this reason sow thinly and plant early. Turnips may now be sown with little risk of their running to seed, but no more should be put in at one time than will afford a supply until the next sowing is ready. As the ground becomes cleared of broccoli it should be dug in readiness for another crop. Where land is plentiful and there is no necessity for over cropping, it may be reserved for runner beans or celery, but where space is limited late potatos may be planted. As the frames become cleared of potatos, French beans and other crops, they may be planted with vegetable marrows, cucumbers, tomatos, &c. The latter are always useful later in the season. Pot on capsicums and other tender plants before the pots become crowded with roots, and pay special attention to all small plants that they do not suffer for want of water. There are so many things needing attention now that a little neglect is apt to throw one back for a considerable time. All vegetables under glass must be allowed abundance of air on all favourable occasions and the syringe should be brought into play where red spider makes its appearance. Do not neglect the sowing of small salads, as these will be in greater request as the weather becomes warmer; though growth is made much more quickly there is a greater danger of the supplies running short on account of the salading so soon becoming unfit for use.—H. C. PRINSEP, *Buxted Park Gardens.*

FRUITS UNDER GLASS.

PLANTED-OUT figs which were started early in the year will now be taking their final swelling, and will be ripening in the course of a few days. I usually have the first dishes of brown Turkey about the 25th of April, and just previous to their ripening I have the borders thoroughly soaked throughout with liquid manure, heated to about 90 degrees. The borders at this stage cannot have too much water, as the strain of a heavy crop during the next few weeks will be [illegible] for, in addition to the ripening crop, the second crop will be showing on the new wood. I lay especial emphasis on the timing of the heavy watering [illegible] recommended, as I have repeatedly found that, when given at the right period, it influences greatly the size of the individual fruits, and vastly increases their value for home use or for sale. Particular attention must also be paid to such trees in the matter of syringing, and I recommend that they should be heavily syringed morning and afternoon, to remove every vestige of red spider previous to ripening the fruit, as it will only be possible to give occasional syringings from that time until the crop is removed, and, if spider is in evidence previously, the second crop and the leaves will be stunted and disfigured. Keep up a brisk growing temperature, ventilate early, and increase the ventilation gradually, so as to reach the maximum about eleven a.m.; shut up and syringe soon after two o'clock. I should have mentioned that when the liquid manure given the borders is strongly impregnated with ammonia, in which stable drainings, for instance, are especially rich, air should be left on the house until the sun goes down, and put on again before [illegible] the next morning, as the fig leaves are very liable to scorching under the influence of an atmosphere heavily charged with ammonia. Pot trees which have been divested of their crop should not be neglected. All small growths, except [illegible] wanted for the production of branches, should be cleaned out to prevent the crowding of the better wood. The pots should be turned round once a week so that each side of the tree may have the benefit of full sunlight.

Strawberries ripened after this date will be better flavoured than the earlier ones, still, to have them at their best, one or two precautions are necessary; and, in addition to keeping the plants well apart, and close to the glass, a great improvement in flavour may be brought about by withholding water for several hours before gathering. The early morning is the best time to gather, as the [illegible] are then cool, and they may be kept in good condition for several hours if [illegible] thinly in boxes lined with cotton wool, on which have been spread a few [illegible] other soft leaves. Where the fruits have to be packed and sent away by [illegible] rail, it is necessary to pack them in strong shallow boxes holding one layer [illegible] and each fruit should be enclosed in a spinach leaf of suitable size before placing in the box. Firm packing, without undue squeezing should be the aim. After a trial of many kinds of leaves, their own included, for packing strawberries, I have found none to equal spinach, which are of a cool nature, and of good substance, and I recommend their use to those who have never tried them; they should only be allowed to become slightly flagged before use, as, if left too [illegible] difficult to handle. Routine work among strawberries will consist in setting the flowers when they open, giving the plants with swelling fruits plenty of liquid manure till colouring commences, after which clear water only is advisable, thinning to the requisite number of the best formed fruits, and in hurrying on later batches as fast as room can be found for them. Before being placed in the forcing house the plants should be dipped in some approved insecticide, and for that purpose I have been using this year, for the first time, the X.-L. All insecticide, with which I am greatly pleased. The latest batches should now be removed to cold frames where possible, as they will then commence to grow gently, and will require very little more than cool-house treatment to ripen their fruits, just in advance of the earliest outdoors. The possessors of well-stocked, cool and orchard houses will have reason to congratulate themselves on their possession this year. The night frosts have been severe here for the time of year, and prolonged, and much of the blossom on wall plum trees, &c., has been killed; very few nights have passed lately without a register of ten or twelve degrees of frost, and this, succeeded by bright sunny days, is too much for such tender blossoms. The trees under glass should be kept as cool as may be, and well aired. They will require but little other attention just now, except to see that they do not become dry at the roots, and to keep down insect pests.—J. C. TALLACK, *Livermere Park Gardens.*

HOME-GROWN APPLES.

It is very satisfactory to be able to record the advance that home-grown apples appear to have made in public favour during the past season, as in quite remote parts of the country they have been offered for sale alongside those of foreign growth, and in every instance that has come within my notice they have stood the test well, and have been much appreciated by purchasers.

An acquaintance of mine in this county who supplies large quantities of fruit over a widely extended district, was last autumn bewailing the unsatisfactory condition in which the American apples were arriving; and he had just cause for complaint, for of several barrels opened at one time not one proved to be of good quality throughout, and some of them contained fruit that was decidedly inferior both in size and quality, and being badly bruised through faulty packing, much of it could hardly be disposed of at a profitable rate. I had often previously advised him to give English-grown fruit a trial, but to no purpose, as he considered that the American article had got such a firm hold of the market that any of the home-growth, however fine it might be, could not successfully compete against it. On this occasion, however, the circumstances already related favoured a trial of the latter being carried out, and an order was eventually sent to a Herefordshire grower for a small quantity of the best market apple then in season, leaving the choice of the variety entirely to himself.

In response to the order, a very fine sample of Blenheim Pippin was received; these were well-selected, and the packing of them so well done that scarcely a fruit was marked, and when exposed for sale they quickly drew the attention of customers; and although the price was at first thought to be rather high, this objection was soon overcome, as the quality either for dessert or culinary use was all that could be desired, and the fruit, owing to its soundnes, could be kept a considerable time without deterioration. The first consignment was disposed of in a short time, and other orders were dispatched at intervals throughout the season—as long as the variety was obtainable. The vendor has since expressed himself as well satisfied with the results of the venture, as the fruit in every instance arrived in excellent condition, and the demand for it increased as its merits became more known, and customers were willing to pay a good price for a good article. He intends in future to increase this branch of his trade.

This is only one case where preference for home-grown *versus* foreign apples has been shown; but as it occurred in a district where for many years the latter have furnished the principal supply, I thought it worthy of mention, as it proves that if fruiterers could be induced to invest in good apples of home-growth the public are willing to purchase the same, and would thereby promote the development of a profitable home industry. In this part of Scotland there are not at present any orchards for supplying the wants of the population, and it is only in years when the fruit crop is very abundant that apples grown in private gardens are obtainable, and only then for a very short time in the gathering season. The supply from this source consists principally of sorts that quickly deteriorate after reaching maturity, or of those not worth storing. Fruit of this description commands a ready sale, and at a price frequently as high as can be obtained for the best samples in a fruit-producing county at that season. To aid in the better distribution of home-grown apples some method is needed whereby the producer and retailer, or even the consumer, may become better acquainted with each other, as at present very few of the most constant readers of horticultural literature could, I fear, give the necessary information to an inquirer to enable him to apply direct to the grower for a supply of fruit. If the system of advertising so largely carried out in all matters connected with the garden was applied to fruit also, not only in the horticultural papers, but in the pages of local newspapers as well, giving the price and description of the different varieties as they came in season, it would greatly tend to open up a profitable trade to the benefit of all concerned.

Galloway House, Wigtownshire. JAMES DAY.

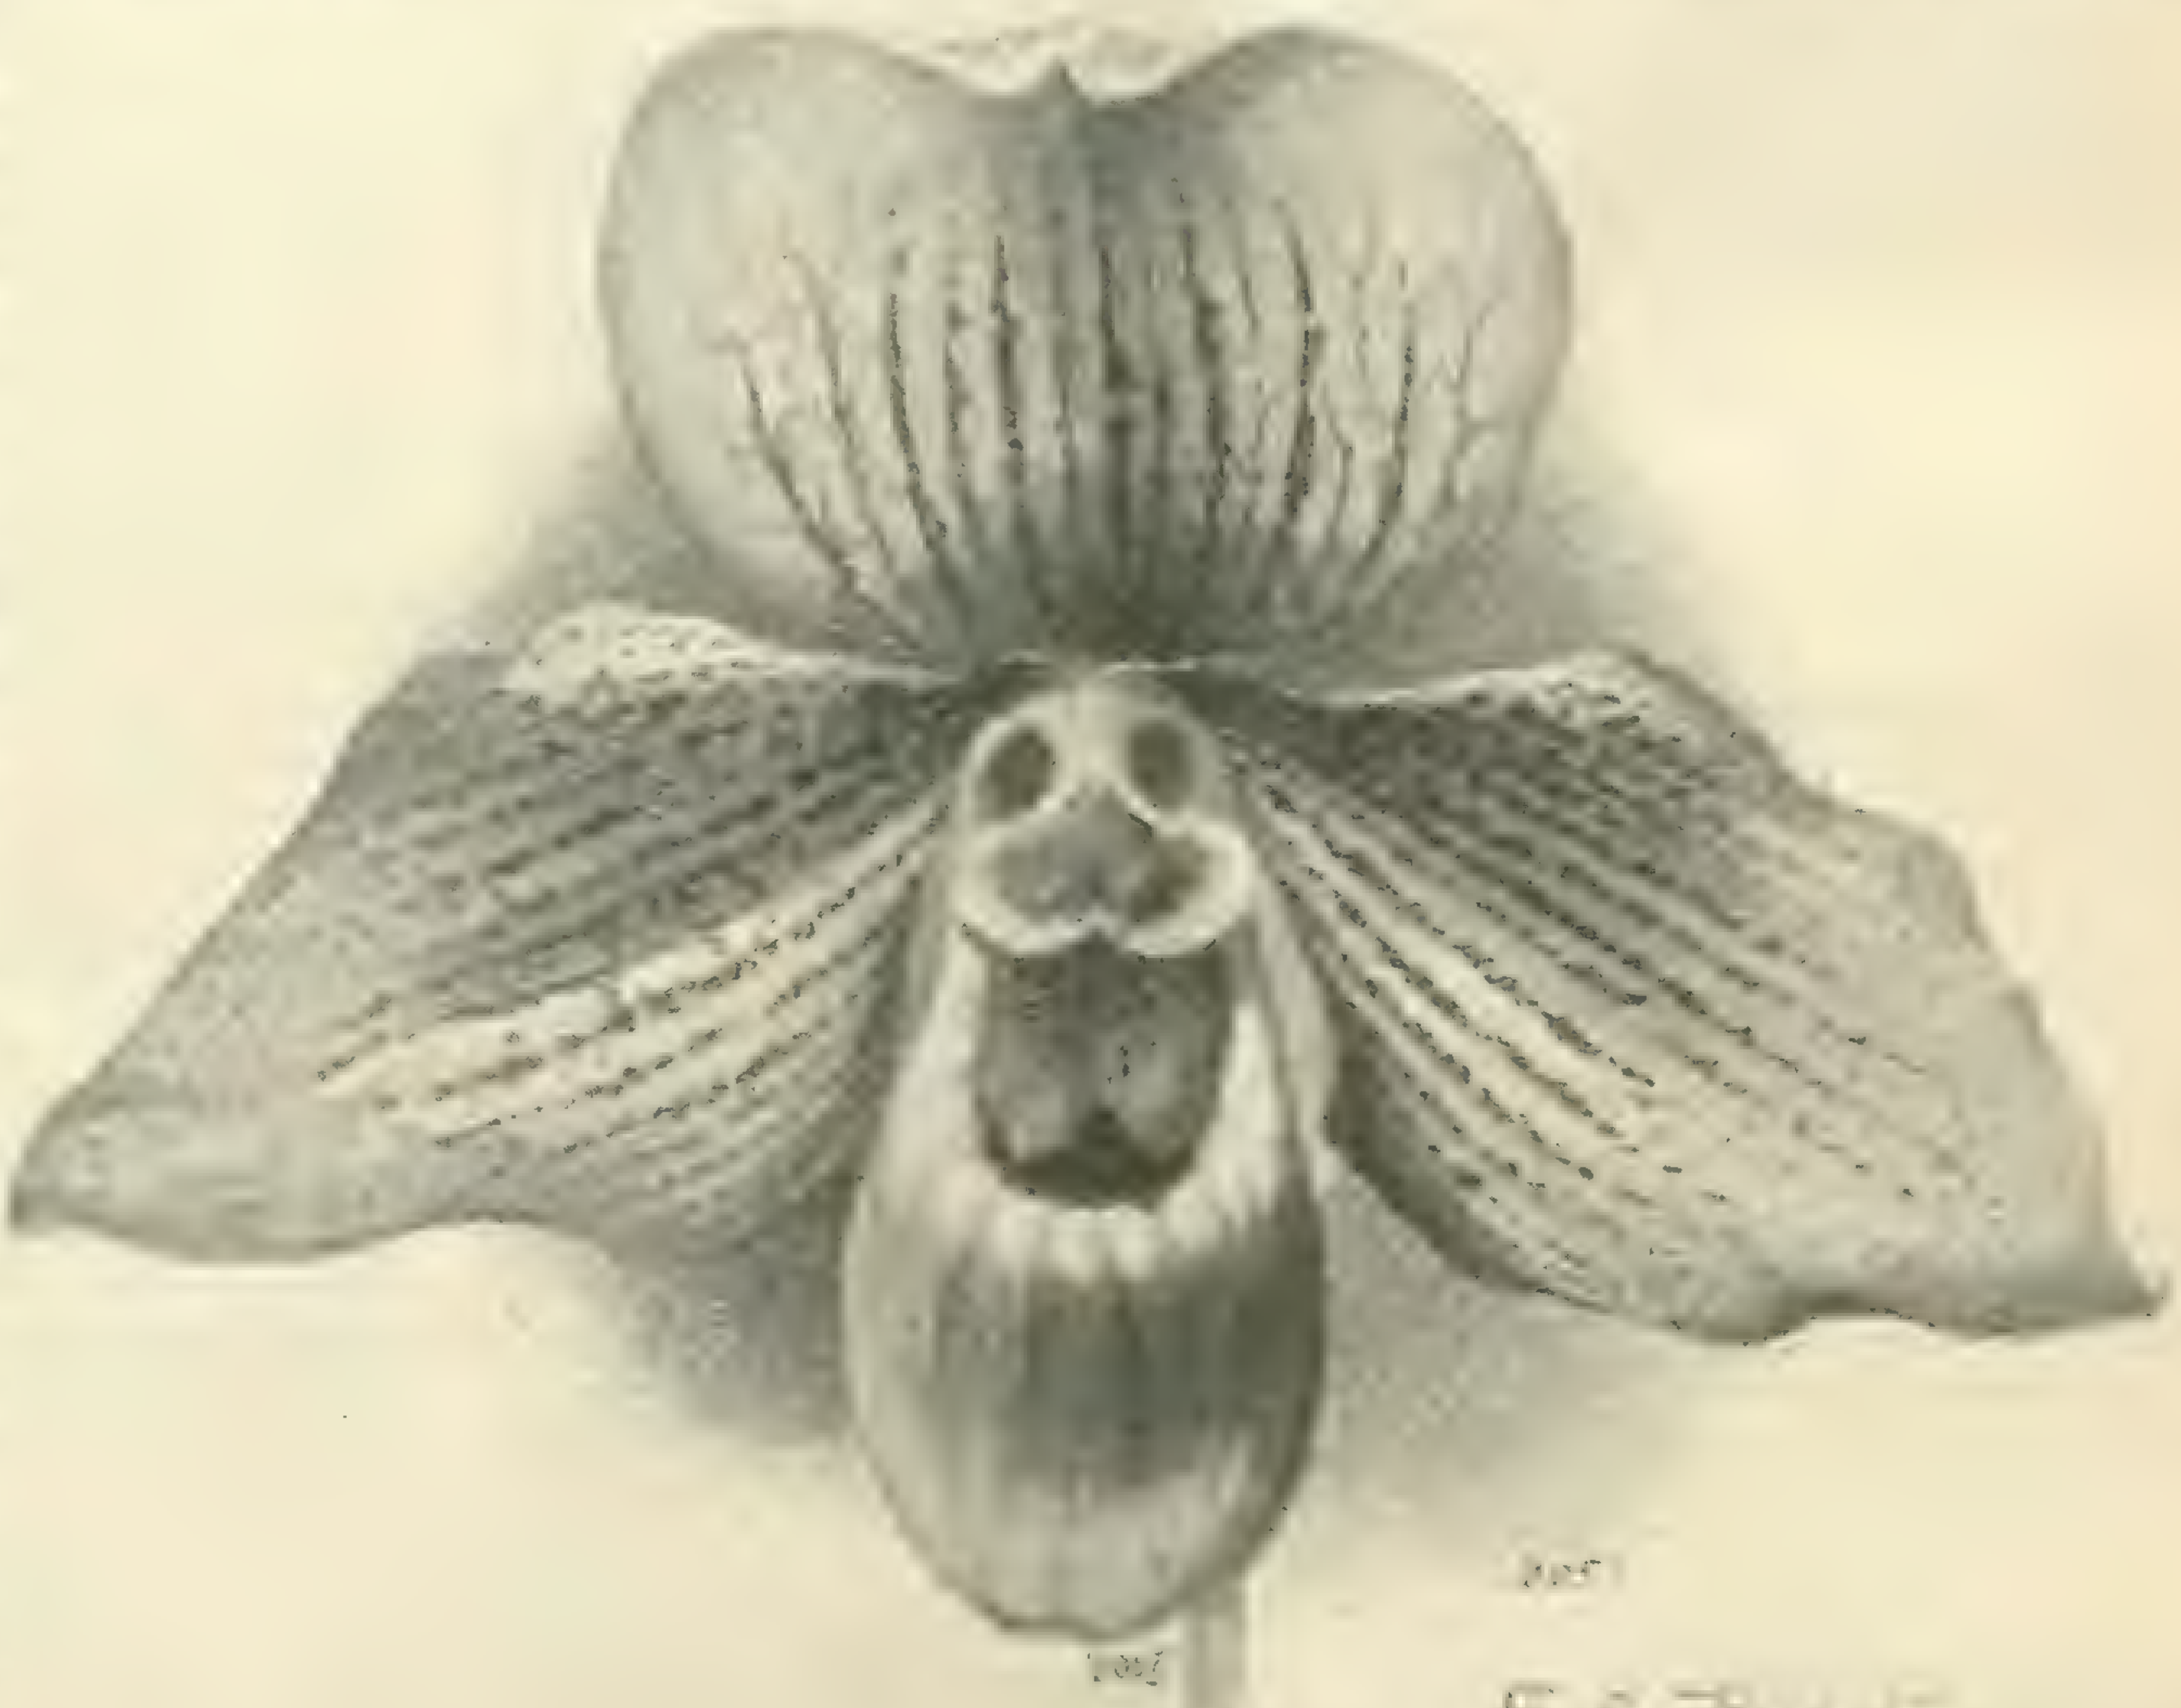
NOTES ON ORCHIDS.

ONCIDIUM SARCODES.

UNDOUBTEDLY this is one of the most useful and easily managed of oncidiums. Like some other species it appreciates more warmth during the winter months than is afforded the majority of odontoglossums, while at the same time it needs to be always kept moist, though little water is needed during the season of comparative rest. The bright yellow flowers, heavily spotted and blotched with red-brown, are borne in long, slender, and graceful branching spikes, the latter varying from three to five feet in length. These need to be supported, but their beauty is altogether spoiled when several spikes are wound round a balloon trellis or one made of stout stakes. Select a few tough osier stems, or similar green sticks, and place one to each spike varying the length and stoutness according to the weight to be supported. If the specimen is to stand in a conservatory, or elsewhere where it has to face a certain direction, then the spikes should be disposed so as to droop gracefully in a half circle. If standing alone, then the spikes may depend all round. The use of tough and somewhat pliable stakes is a great advantage for this and other long-spiked orchids, as it prevents stiffness of appearance, and the green bark is not so prominent as green paint on deal stakes. Oncidium sarcodes was first received in England by the Royal Horticultural Society in 1849. C.

CYPRIPEDIUM F. S. ~~AMES.~~ Roberts.

This is a new cypripedium which has a general resemblance to C. Cowleyanum, and like it was probably raised by crossing C. niveum with C. Curtisi. In the case of the hybrid in question the pollen parentage has not been recorded. When Cypripedium F. S. Ames was exhibited by Messrs. Hugh Low and Co., Clapton, on January 11, at the Drill Hall, it was the chief attraction in their group. The flower is of good size, as will be seen by the accompanying illustration. The large and rounded dorsal sepal is white shaded at the base with rose, and also heavily veined and lined with deep rose. The broad sepals stand out boldly, and have reflexing tips; in colour they are similar to the dorsal sepal, with additional spottings and dots of deep purple. The lip betrays the influence of C. niveum by its shape and rounded opening; it is large and fully pouched, rose-coloured, veined with dark rose or even a purple flush; base white. Measured across the fully expanded petals the flower has a breadth of four and three-quarter inches. Cypripedium F. S. Ames is a welcome addition to the hybrids of C. niveum.—C. K.



CYPRIPEDIUM ~~F. S.~~ AMES. See p. 256.

CATTLEYA SCHILLERIANA.

This orchid appears to be flowering earlier than usual in the majority of establishments. It varies considerably in colour, but in the more recent importations there has been a large percentage of fine forms. Many will remember the magnificent C. Schilleriana Hardy's var. shown at the Temple Show, in 1897, by F. Hardy, Esq., Tyntesfield, Ashton-on-Mersey; this superb orchid was figured in the GARDENERS' MAGAZINE on that occasion on p. 311, May 29, 1897. Reichenbach named the species after Consul Schiller, in whose collection, at Hamburg, it first flowered in 1857. Two years later a much different type was sent to Kew by the Messrs. Backhouse of York, and this Sir W. Hooker named C. Schilleriana concolor. The species comes from Brazil, and bears some considerable resemblance to C. Acklandiæ, but has darker and rounder leaves. Judging from appearances there are grounds for the belief that C. Schilleriana is a natural hybrid between C. Acklandiæ and C. guttata. Some difficulty is sometimes experienced in keeping the flowers fresh for any time, but this may be managed by placing the flowering plant in a drier atmosphere than it previously experienced. Do not, however, allow the flowers to stay on the plant until they fade; a fortnight is quite long enough, then cut them and stand in a tube of water. H. C.

THE BEST GUIDE to the garden for the whole year is the "Gardening Year Book," containing practical articles on the cultivation of Flowers, Fruit, Vegetables, &c. Price 1s. "Gardeners Magazine" Office, 4, Ave Maria Lane, London.—[ADVT.]

HUMUS IN ITS RELATION TO SOIL FERTILITY.

The term humus is applied to a large class of compounds derived from the decay of former animal and plant life. The animal and vegetable materials (organic matter) undergo decomposition in the soil, the final result of which is the disappearance of these substances, leaving only a few gases and a small amount of mineral matter. When the organic matter is in its intermediate stages of decomposition, and mixed with the soil, it is known as humus. Opinion as to the fertilising value of humus has swung, pendulum-like, from one extreme to the other. The alchemists taught that the spirits left the decaying animal and vegetable matters and entered plants. By many of the earlier chemists, humus was considered as supplying the larger part of the materials necessary for the development of the crop, but when the combined labours of De Saussure, Boussingault, Dumas, and Liebig demonstrated that the air supplied plants most of their food, particularly that part which was supposed to come from humus, scientists, as a rule, assigned a low value to humus. From the very earliest times, however, farmers have assigned a very high value to humus as a factor of soil fertility, and this belief was strengthened by the observed facts that soils rich in humus were, as a rule, highly productive, and that such materials as animal excrement or barnyard manure, which supplied the soil with an abundance of humus, possessed a marked fertilising power. Although many of the old theories which were supposed to account for the value of humus are no longer tenable, recent experiments have shown that there are sound scientific reasons for ascribing to humus a high value as a factor of soil fertility, and have demonstrated that "farmers are wholly right in attaching great importance to the preservation of humus in their soils." As the account by Prof. H. Snyder, B. Sc., Minnesota University, given in the Year Book of the U. S. Department of Agriculture will show, humus performs a number of different functions in the soil which are of the highest importance in crop production. It influences the temperature, tilth, permeability, absorptive power, weight, and colour of soils, and directly or indirectly controls to a high degree their supply of water, nitrogen, phosphoric acid, and potash.

Loss of Soil Humus and Decline in Fertility.

A virgin soil or one recently cleared may show a high state of productiveness for a number of years after it is brought under cultivation. Gradually, however, a decline in fertility is observed, which is slight at first, but more marked after a lapse of fifteen or twenty years. Experiments have shown that the decline in fertility is not entirely a result of the removal from the soil of the essential fertilising elements—nitrogen, phosphoric acid, potash, or lime—but is due in many cases to getting the land out of condition through a loss of humus. Experiments conducted by the Minnesota Agricultural Experiment Station on different types of soils worn by continuous grain cropping have shown that when a fertiliser was used containing nitrogen, phosphoric acid, potash, or lime, or when any one of these materials was applied alone, there was "in no case an increase of over three bushels per acre of wheat and two of flax. * * * With soils that have been cropped for twenty years, the largest increase was four bushels per acre." The difference between the grain-producing power of new soils and of worn soils of the same original character was about fifteen bushels per acre. These results, as well as many others which could be quoted, make it clear that the decline in fertility of the soils was not entirely due to a loss of the essential elements of fertility, and that we must seek the cause elsewhere.

The most important difference, physical or chemical, between the composition of old, worn soils and new soils of the same character is in the amount of humus which is presents. That the loss of humus is an important factor in the decline of fertility is also indicated by the fact that with methods of farming in which grasses form an important part in the rotation, especially those that leave a large residue of roots and culms, the decline in productive power is much slower than when crops like wheat, cotton, or potatos, which leave little residue in the soil, are grown continuously. Under grass and similar crops the soil humus increases from year to year, while the continuous culture of grain, cotton, or potatos gradually reduces the original stock of humus. Grass and grain crops in rotation result in alternately increasing and decreasing the humus of the soil and keep the land in a higher state of productiveness, although more nitrogen, phosphoric acid, and potash is removed from the soil than when grain, cotton, or corn is raised continuously. In no case, however, do those systems of farming which return humus-forming materials to the soil reduce the land to so low a state of productiveness as do those systems in which there is a continual loss of humus from the soil. Agriculturally considered, the two most important points regarding the composition of humus are (1) the presence of nitrogen as a constant constituent, and (2) the chemical union of the humus with potash, lime, and phosphoric acid, forming humates.

Nitrogen in Humus.

Humus, as ordinarily obtained from the soil, contains from 3 to 12 per cent. of nitrogen. According to Professor Hilgard, the soils from arid regions are poor in humus, containing from 1 to 2 per cent., but this humus is correspondingly rich in nitrogen, in many cases containing 14 per cent. In many of the prairie regions the soil contains about 5 per cent. of humus, and this humus contains about 10 per cent. of nitrogen. Since, therefore, nitrogen is one of the prominent constituents of humus, it is easily understood how a loss of humus has also resulted in a loss of nitrogen. This decline in the nitrogen content of the soil is one of the most serious results of the loss of humus from the soil. A virgin soil containing 4 per cent. of true humus and 0.35 per cent. of nitrogen will after twenty years of grain cropping show about 2·5 per cent. of humus and 0·2 per cent. of nitrogen. In the twenty years, therefore, there has been a loss of 1·5 per cent. of humus, equivalent to about 3,500 pounds per acre, and 0·15 to 0·2 per cent. of nitrogen, which is equivalent to 3,000 to 5,000 pounds of nitrogen per acre. Since fifty pounds per year of nitrogen is a large quantity for any ordinary grain crop to remove, the twenty crops have at the most removed nine hundred pounds of nitrogen. At least 2,500 pounds have, therefore, been lost by the decomposition of the humus, the nitrogen being lost either in the free state or in the drainage waters. For every pound of nitrogen removed in the crops during the twenty years of cultivation there has been an additional loss of three or four pounds of nitrogen from the soil by the decomposition of the humus.

We know that most if not all of the changes that organic matter undergoes are the result of the action of microscopic organisms. Such changes as nitrification, or the transformation of organic nitrogen into nitrates and its opposite denitrification, or the reduction of nitrates to the gaseous nitrogen, besides many others which might be mentioned, are illustrations of the work of these minute organisms. Humus furnishes a medium peculiarly adapted to the activity of these organisms. The decomposition of humus, by which it loses its nitrogen, is due chiefly to the combined action of the organisms of nitrification and denitrification. The nitrifying organism feeds upon the humus, breaking down its organic nitrogenous constituents and producing nitrates which may be washed out in the drainage, and the denitrifying organism completes the work by feeding on the nitrates, producing free nitrogen gas, which escapes into the air. Nitri[illegible] is one of the most important natural provisions for rendering the inert [illegible] of the soil available to plants, and a certain amount of it is necessary [illegible] growth, but it can be readily seen that under injudicious management [illegible] tion of the soil it may work a positive injury by causing unnecessary waste of [illegible] nitrogen, or, in case of rich soils, it may supply the growing crop with [illegible] much nitrate and thus produce a rank growth of straw and leaves.

Bare summer fallowing is widely practised, and has been very beneficial [illegible] the succeeding crop by increasing the available nitrogen of the soil, but frequently more nitrogen is rendered available than is necessary for the following crop, and whatever the crop is unable to utilise is lost by leaching or else escapes into the air. The available nitrogen is thus increased, while the total nitrogen is greatly decreased. Experiments at the Minnesota Agricultural Experiment Station indicated that one year of fallowing caused a gain of 0·0022 per cent. of available nitrogen and a loss of 0·0114 per cent. of total nitrogen in a soil containing originally 0·1536 per cent. of total nitrogen and 0·0002 per cent. of available nitrogen. For every pound of nitrogen rendered available by the [illegible] treatment there was a loss of over five pounds of nitrogen from the soil. Bare summer fallowing is, therefore, only temporarily beneficial at the expense of the total humus and nitrogen of the soil. When a soil is poor in humus and nitrogen the loss of nitrogen is much smaller, but even then it is doubtful whether bare summer fallowing is a wise practice. In no case should summer fallowing be practised on a new soil. Autumn cultivation keeps the humus and nitrogen of the soil in better condition than late spring. Nitrification goes on in the soil until quite late in the fall, and in the south the process goes on the entire year. The change is most rapid near the surface, where there is plenty of oxygen from the air. In early fall ploughing the available nitrogen formed from the humus is near the surface, where it does the sprouting seeds and the young crops the most good. With late spring ploughing this available nitrogen is ploughed under, and inert organic nitrogen is brought to the surface. In old soils the process of nitrification does not go on rapidly enough to furnish available nitrogen to the crop. In a new soil the process of nitrification is liable to go on too rapidly. Deep ploughing and thorough cultivation aid in nitrification. Hence the longer the soil is cultivated, the deeper and more thorough must be its preparation. Ploughing must be done at the right time, preferably in the fall, so as not to interfere with next year's water supply. The application of lime and wood ashes aids in the reduction of nitrogen of humus to available forms and prevents the formation of sour [illegible]. Good drainage is also necessary to nitrification in the soil. In water-logged soils the humus does not decompose normally, but peat is produced on account of the absence of oxygen. We thus see that nitrification, although sometimes a serious source of loss, may be largely controlled by the management of the soil.

Another source of loss of humus in the prairie and forest regions is the frequent burning over of the land. Soils covered with pine, in which sand largely predominates, frequently lose half or three-quarters their total nitrogen when visited by forest fires. The sand, being of an open and porous nature, aids in the [illegible] complete combustion of the humus. In the timbered regions of the North-west the great forest fires of 1894 resulted in the average destruction of 1,500 pounds of humus nitrogen per acre, to say nothing of the nitrogen lost in the burning of the timber. Analyses of soils, before and after the fire, made by the Minnesota Agricultural Experiment Station showed a loss in some cases of 2,500 pounds per acre of nitrogen, equivalent to a loss of 75 per cent. of the total amount in the soil. The prairie fires have not been so destructive upon the humus as the forest fires, because the burning has been confined more to the surface. An average prairie fire, however, will remove more nitrogen from the soil than five [illegible] crops of wheat.

Mineral Matter in Humus.

Besides being a great reservoir of nitrogen, humus is an indirect means of supplying the plants with other fertilising constituents. Humus as it occurs in the soil is combined with potash, lime, phosphoric acid, and other compounds which are essential as plant food. The decaying animal and vegetable matters form various organic acids, which combine with the potash, lime, iron, and alumina, as well as with other elements, and form a series of compounds known as humates, of which but little is definitely known. By some, the potash, lime, and other mineral constituents of the humus are regarded as simply associated with the humus and not organically combined with it, but there are a number of facts which indicate that the union is chemical and not simply mechanical. The mineral matter combined with the humus is characteristically rich in phosphoric acid and potash, two compounds which are of great value agriculturally. The mineral matter combined with the humus from different soil types, however, is not always of the same nature, and the amount of plant food thus combined with humus has not been extensively investigated. In the case of rich prairie soils over 1,500 pounds of phosphoric acid and 1,000 pounds of potash per acre to the depth of one foot have been found to be in combination with the humus. In the case of soils poor in humus and worn by cropping, the amount may be reduced to 100 pounds per acre. The average of analyses of the mineral matter of the humus from [illegible] productive prairie soils yielding 25 per cent. of humates showed 7.50 per cent. of potash and 12.37 per cent of phosphoric acid. In these soils, which were well supplied with humus, 1,500 pounds of phosphoric acid per acre out of a total of 8,750 was combined with humus, and 1,000 pounds of potash out of a total of 12,250 pounds. According to Hilgard, the amount of phosphoric acid [illegible] found associated with humus varies from 0.1 to 0.5 of the total amount in the soil, indicating in many cases the amount of this element available to plants.

Value of Humates as Plant Food.

The value of these various forms of humates as plant food has been the subject of extensive investigations and many of these experiments indicate that the humates, when acted upon by the proper micro-organisms, are very valuable forms of plant food. At the Minnesota Agricultural Experiment Station oats and [illegible] have been successfully grown when the only forms of mineral food were [illegible] potash, lime, magnesia, iron, and humic phosphate and sulphate. [illegible] material obtained from rich prairie soil was mixed with pure sand, which [illegible] practically no plant food, and gypsum was added to prevent the formation of [illegible] humus. The mixture was watered with leachings from a fertile field, [illegible] introduce the organisms which usually carry on the work of humus decomposition. Oats seeded in the soil thus prepared finally produced fertile seeds, the [illegible] plants containing fifty times more potash than was in the seeds sown, and [illegible] sixty times more phosphoric acid. The only source from which the plants [illegible] obtain these substances was the humates added to the soil. In experiments [illegible] which the soil leachings were omitted the oat plants made only feeble [illegible] growth, plainly showing that unless the potash, phosphoric acid, &c., [illegible] with the humus is set free by the action of the micro-organisms the plant is [illegible] to use them. There are a number of facts in field practice which also [illegible] plants are capable of feeding on humates. The roots of plants, particularly [illegible] of grains, will always be found clustering around any decaying vegetable [illegible] that may happen to be present in the soil. When wheat or oats follow a corn crop the roots of the grain will be found in many cases to completely incase any decaying pieces of cornstalks that are present. The cornstalks are not rich in plant food, but they decay in the soil and combine with the soil potash, phosphates, &c., forming humates which the grain feeds upon. Large piles of sawdust many feet in height and circumference are frequently left around sawmills, or the sawdust is used for filling in low places. The sawdust is very slow in decomposing, but in time it is covered with vegetation which must obtain most if not all of its mineral food in the form of humates.

Means of Increasing the Humates of the Soil.

Inasmuch as both experiments and observations in the field appear to strongly indicate that plants have the power of feeding upon humates, it becomes important to determine to what extent the addition of animal and vegetable matters to the soil is capable of affecting the amount of available plant food.

Experiments conducted at the Minnesota Agricultural Experiment Station have an important bearing upon this question. To a box holding one hundred pounds of loamy soil twenty pounds of cow manure was added. The contents of the box were kept moist and well mixed. At the end of twelve months the amount of mineral matter combined with the humus was determined, and the amount found compared with that originally in the box. Another box containing an equal amount of the same soil to which no manure was added was treated in the same manner. In the first case the mineral matter originally present in the manure was deducted, as well as the amount which was only soluble in the solutions used in the analysis. The results were as follows :—

Increase of Humates in the Soil due to Applications of Manure.

	Total humates in 100 pounds of original soil.	Total at the end of 12 months in manured box	Gain of humates from soil through manure.	Total humates at the end of 12 months, no manure.	Loss when no manure was added.
	Grams.	*Grams.*	*Grams.*	*Grams.*	*Grams.*
Potash	7.25	9.14	1.89	6.92	0.33
Soda	7.84	10.11	2.27	7.50	.34
Iron	2.44	4.13	1.69	2.46	—
Magnesia	.35	.54	.19	.27	.08
Alumina	2.96	4 64	1.68	2.75	.21
Phosphoric acid	11.97	13.99	2.02	11.50	.47

As will be seen, the cow manure increased the amount of mineral matter combined with the humus to the extent of fifteen to twenty-five per cent. of the original amount present in the soil. In addition to adding new elements of fertility to the soil, it has also resulted in changing a part of the potash, magnesias and phosphoric acid, as well as other solid elements, into forms more valuable as plant food. The manure, therefore, not only has a direct fertilising value, but is also useful in making the inert plant food of the soil more available. A number of facts in field practice also point to the same conclusion. It is well known that barnyard manure is among the most lasting in effect of any of the fertilisers which can be applied. This is undoubtedly due to the power which the manure possesses of uniting with the soil potash, phosphoric acid, &c., to produce humates.

It has been frequently observed that when potatos are cultivated on new prairie land for three or four years in succession, both the yield and the size of the potatos decrease. When the land is seeded to a grass crop, the sod ploughed under, and potatos again planted, the yield and size of the potatos are often nearly the same as when the land was new. This result has been attained without the addition of any manure to the land except the vegetable matter in the sod which has furnished materials for the formation of humates. In the same way, wheat grown continuously on prairie soil will gradually decline in yield, but if grass is alternated with the wheat, nearly the original yields are restored. Besides performing the useful functions just discussed, which are essentially chemical in character, humus profoundly modifies the physical properties of soils. This influence is most marked in relation to the water content and temperature of the soil.

(To be continued.)

ROSE SHOW FIXTURES IN 1898.

June 15 (Wednesday).—*York.
,, 16 (Thursday).—Colchester.
,, 23 (Thursday).—Bath (N.R.S.).
,, 25 (Saturday).—Windsor.
,, 28 (Tuesday).—†Southampton, Sutton, and Westminster (R.H.S.).

,, 26 (Tuesday).—Tibshelf.

* Shows lasting three days. † Shows lasting two days.

The next list of fixtures will appear early in May. In the meantime I shall be glad to receive the dates of any rose shows (or other horticultural exhibitions where roses form a leading feature) for insertion in that list.

Rosebank, Berkhamsted, Herts. EDWARD MAWLEY.

SENTENCED TO DEATH.—These are the most terribly significant three words we have in the English language. Thousands of wretched creatures, whose lives have become forfeited to the outraged laws of their country, have heard them pronounced with feelings of sickening terror. The man who has neglected the most simple laws of health feels that all is indeed lost, when the dread sentence is pronounced by the doctor, who has used all his medical skill upon him in vain. In the latter case, however, the door of hope has been opened, through the medium of Holloway's Pills and Ointment. They have effected a cure at the last moment, as thousands of testimonials, being constantly received, will prove.—[Advt.]

EXHIBITIONS AND MEETINGS.

ROYAL HORTICULTURAL SOCIETY, April 12.

NOTWITHSTANDING the rough weather and the date of exhibition falling next to Easter Monday, there was a first-rate show on the above occasion at the Drill Hall. Daffodils were naturally very plentiful, so also were forced plants, roses, and orchids. Fruit and vegetables made up a very small show.

FLORAL COMMITTEE.

There was a splendid display before this body, and it was remarkable for variety and extent. Cinerarias, daffodils, ferns, and roses were very prominent.

Pot roses were staged by Messrs. Paul and Son, Cheshunt, and made a good display ; among the most notable varieties were Madame Hoste, Rev. Allan Cheales, Antoine Revoire, a beautiful rose, La France, Innocente Pirola, Captain Hayward, Madame Chedane Guinoisseau, Bacchus, and Catherine Mermet. Mr. H. B. May, Edmonton, made a pretty exhibit of spiræas, hydrangeas, and Crimson Rambler roses, grandly flowered, set amid well-grown pterises and maidenhair ferns ; a few clematis were included. Cinerarias from Messrs. J. Carter and Co. were bright, fragrant, and well grown ; the heads and flowers were both large, and the specimens were not too stiff in general appearance, but showy and pleasing both to gardener and florist.

Ferns in considerable variety were staged in fine condition by Messrs. J. Hill and Co., Edmonton ; maidenhair ferns were well represented, so were aspleniums and pteris ; the gymnogrammas excited a great deal of attention. Mr. W. Kemp, the Gunyah, Barnes, put up a group of Azalea indica in considerable variety ; the plants were small but freely flowered and fine for conservatory decoration ; Apollyon, white ; Theodore Reimers, purplish-rose ; and La Victoria, salmon-red, were three distinct varieties. The whole group was edged with fragrant lily of the valley. A group of light and elegant cinerarias, hybrid forms between the garden or florist's cineraria and C. cruenta, came from Messrs. J. Veitch and Sons, Chelsea ; the deep blue and the lilac forms were exceedingly pretty and effective. The same firm showed Azalea obtusa alba, a dwarf white-flowered form, Rhododendron racemosum, Deutzia Lemoinei, and Azalea carminata splendens. Streptocarpuses in variety were shown by Messrs. J. Laing and Sons, Forest Hill. the flowers were of an immense size and borne freely on erect stems ; the deep purple and blue varieties were especially attractive, but all were good. Mr. Miller, gardener to Lord Foley, Ruxley Lodge, Esher showed a splendid lot of Marie Louise violets and a few bunches of Leedsi and Ajax daffodils. Messrs. W. Paul and Son, Waltham Cross, once again showed camellias, thus proving that these handsome plants and flowers are available over a long season.

Mr. H. Walters, gardener to Lord Gerrard, Eastwell Park, Kent, staged three dozen splendid blooms of Maréchal Niel roses and a few blooms of other sorts. Mr. C. Turner, Slough, showed three baskets of Nepeta glechoma variegata ; this makes an extremely elegant basket plant, the slender growths and prettily-variegated foliage depending gracefully. Mr. R. Brown, gardener to F. Barry, Esq., Windsor, sent several dozens of camellia flowers that had been produced on unprotected trees. Forced laburnums, deutzias, and Staphylea colchica made up a fine and showy group from Messrs. W. Cutbush and Son, Highgate. Messrs. Sutton and Sons, Reading, made a pretty exhibit of cinerarias ; these were tall-growing forms obtained by crossing the florist's form with C. cruenta or vice versa. The spreading heads of flowers are large and graceful, fine for grouping or for conservatory decoration, and in a variety of colours from palest lilac to deepest purple-blue. These forms vary in height from two to four feet and are extremely useful.

Roses in quantity came from Mr. W. Rumsey, Joynings Nursery, Waltham Cross ; Maréchal Niel, Mrs. Rumsey, Niphetos, Ethel Brownlow, Reine Marie Henriette, and Safrano were the varieties most extensively staged ; the blooms were much admired and their fragrance appreciated. A magnificent set of ten dozen exquisite blooms of Maréchal Niel roses was staged by Mr. J. Walker, Thame, Oxford ; these were a very fine lot. Messrs. R. Wallace and Co., Colchester, sent a small collection of Dog's Tooth violets, showing Erythronium revolutum Watsoni, E. Hartwegi, and E. giganteum ; Tulipa Greigi, a beautiful species, was also shown, as well as Iris caucasica, Fritillaria lanceolata gracilis, and F. plurifolia. Mr. W. Bardney, gardener to Sir P. Walker, Osmaston Manor, Derby, showed half a dozen seedling clivias, the varieties Wm. Bardney and May Bardney being especially fine in shape and colour. Mr. E. Beckett, Aldenham House Gardens, Elstree, sent a variegated form of Deutzia gracilis ; the foliage is prettily variegated with cream and pale green.

NARCISSI.

Daffodils were a great feature of the show, and Messrs. J. Veitch and Sons staged a collection of very fine flowers chiefly large and medium crowned varieties : Victoria, Incomparabilis Beauty, Golden Spur, Sir Watkin, Emperor, Empress, Maximus, Horsefieldi, Golden Plover, Captain Nelson, Princeps, Odorous rugulosus, and Incomparabilis Gloria Mundi were splendidly represented and finely coloured.

Messrs. Barr and Son, Covent Garden, had a most extensive collection of daffodils and early spring flowers ; the leading varieties, such as Sir Watkin, Empress, Emperor, C. J. Backhouse, the new Victoria, Incomparabilis Beauty, Henry Irving, Goliath, Barri Conspicuus, Obvallaris, and Michael Foster were represented by big full bunches of handsome blooms. Rarer sorts were naturally not so largely represented, but King of the Netherlands, Johnstoni Queen of Spain, Mrs. Walter Ware, P. R. Barr, Leedsi MM. de Graaff, Sir Stafford Northcote, Madame de Graaff, Weardale Perfection, St. John's Beauty, Minnie Hume, and J. B. M.Camm were well shown. A few hyacinths and saxifragas, &c , also came from Mr. Barr.

A group of seedling and hybrid narcissi from the Rev. G. H. Engleheart was a great attraction to daffodil lovers, Flamingo, Flambeau, Dorothy Yorke, and Lucifer were fine medium-crowned forms. Lady Margaret Boscawen, Homer (a poeticus hybrid), White Queen, Southern Star, white and scarlet crown, Torch, and Sir Walter Scott, also a poeticus form, were among the best. Mr. T. S. Ware, Tottenham, sent numerous varieties of narcissi, but in the majority of instances the bunches were too small to be effective ; doubtless the day following Bank Holiday is not the best one for a show. The leading Ajax forms were staged, and there were bunches of the rich golden Maximus ; a few tulips and primulas flanked the daffodils.

ORCHID COMMITTEE.

Although not extensive the exhibits before this body were of a most interesting character, and several really good novelties were on view.

In the group staged by Messrs. J. Veitch and Sons, Chelsea, there were fine specimens of the beautiful Lælio-cattleya Pallas, Cymbidium eburneo-Lowianum, one bearing three good spikes ; Lælia Latona, with four brilliant blooms, and another with five ; Cypripedium Schröderæ, Lælia Euterpe, Epidendrum elegantulum, Epiphronitis Veitchi, a gem of an orchid; Lælio-cattleya Ascania, a lovely cream and yellow hybrid between Lælia xanthina and Cattleya Trianæ; and Cattleya intertexta, a lovely rich rose-coloured cattleya obtained by crossing C. Warneri with C. Mossiæ; dendrobiums and other orchids completed the group. The Messrs. Veitch also showed Phalænopsis Stuartiano-Manni, a cross between the species named; Epidendrum elegantulum leucochilum; Epidendrum Phœbus, a novel hybrid between C. vitellinum majus and E. O'Brienianum; Lælio-cattleya Cypheri, and Dendrobium Euryclea.

Mr. W. H. White, orchid grower to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, staged a most interesting lot of plants; the centre piece was a magnificent cypripedium—C. Olenus magnificum—whose parents are C. bellatulum and C. ciliolare; its rich claret-coloured markings were splendid. Eulophiella Peetersiana, with rich rose flowers, was represented by the first spike of the species that has yet flowered in this country; Odontoglossum coronarium miniatum, Cymbidium Devonianum, with half a dozen spikes; Leptotes bicolor, Odontoglossum Pescatorei var. Prince of Orange, O. nebulosum candidum, Epiphronitis Veitchi, with fine spikes of bloom; and Masdevallia leontoglossa were among the other orchids staged from this famous collection. Mr. J. Bradshaw, The Grange, Southgate, staged a pretty group in which odontoglossums in variety were arranged around a large Cymbidium Lowianum; Lælia Latona, Oncidium olivaceum, Cattleya Mendeli, and C. Trianæ in variety; Cymbidium eburneo-Lowianum and Cattleya speciossissima were other notable and attractive orchids.

From the Cambridge Lodge collection of R. I. Measures, Esq., Camberwell, Mr. J. Chapman brought Dendrobium nobile Cooksoni, Cymbidium Devonianum, with six spikes, Cymbidium eburneo-Lowianum, Angræcum modestum, Cattleya superba, Cypripedium Chamberlainianum, C. Argo-Arthurianum, C. Merops, and a few curious pleurothallus. Mr. Thorne, gardener to Major Joicey, Sunningdale, staged a group consisting almost wholly of the beautiful Epidendrum (Diacrum) bicornutum; about three dozen spikes were on view, and amid these we noted Brassia Lewisi, Dendrobium atro-purpureum Joicey's var., and Lælia cinnabarina. Mr. King, gardener to J. Colman, Esq., Gatton Park, Reigate, sent Cœlogyne cristata alba, well flowered, a white Lycaste Skinneri, Dendrobium nobile nobilius, finely flowered, Dendrobium Brymerianum, and Miltonia candida. Mr. C. Hamilton, Dunmore Park, Stirling, N.B., sent a grand form of Dendrobium nobile, with a fine lip. Mr. C. Kench, gardener to W. J. Moss, Esq., Wintershill, Bishop's Waltham, sent a fairly good form of Odontoglossum Ruckerianum. Mr. J. Lofthouse, gardener to A. Warburton, Esq., Vine House, Hasleden, sent Odontoglossum crispum Lindeni, and a white form of O. Pescatorei.

From Baron Schröder's collection at the Dell, Egham, Mr. Ballantine brought Odontoglossum Osmani, the magnificent O. crispum Schröderianum, and O. c. Dellense, a yellow-ground form. Mr. H. J. Pitt, Rosslyn, Stamford Hill, showed Odontoglossum Wilckeanum Pitt's var., a huge-flowered form with deep chocolate markings on a light yellow ground. A pretty form of O. Andersonianum, yellow ground, came from Mr. W. E. Walker, Percy Lodge, Winchmore Hill. Phalænopsis Schröderæ, a cross between P. leucorrhoda and P. Portei was shown by Messrs. H. Low and Co., Enfield. Mr. King, Gatton Park Gardens, sent a long branching spike of Odontoglossum ramossissimum.

Fruit and Vegetable Committee.

As before stated, there were but very few exhibits of fruit or vegetables.

Mr. J. Miller, Ruxley Lodge Gardens, Esher, gained a cultural commendation for a basket of fine mushrooms. A cultural commendation was awarded to Mr. J. F. McLeod, Dover House Gardens, Roehampton, for about three dozen good specimens of Brown Turkey figs. Mr. E. Beckett, gardener to Lord Aldenham, Aldenham House, Elstree, merited a cultural commendation for a basket of fine examples of Royal Sovereign strawberries. Mr. Bull, Billericay, sent a seedling apple named Aurora.

Mr. C. Herrin, Dropmore Gardens, Maidenhead, was first with Sturmer Pippin, and Mr. J. C. Tallack, Livermere Park Gardens, second with Court Pendu Plat apples in the Veitch classes for flavour.

Medals.

Silver-gilt Banksian Medal to Mr. H. B. May, Edmonton.

Silver Flora Medals to Messrs. W. Paul and Son, Waltham Cross; Mr. W. Rumsey, Waltham Cross; and Messrs. Paul and Son, Cheshunt.

Silver Banksian Medals to Mr. J. Walker, Thame; Messrs. J. Veitch and Sons, Chelsea; Mr. Thorne, gardener to Major Joicey; Mr. J. Bradshaw, Southgate; and to Mr. King, gardener to J. Colman, Esq., Reigate.

Bronze Flora Medals to Messrs. Wallace and Co., and to Messrs. J. Carter and Co., Holborn.

Bronze Banksian Medals to Lord Gerrard, Ashford; and Mr. W. Kemp, Barnes.

EDINBURGH SPRING SHOW.

THE spring exhibition of the Royal Caledonian Horticultural Society, held in the Waverley Market, Edinburgh, on April 6 and 7, was a distinct success. Narcissi of all kinds, tulips, forced plants, &c., were well represented, while orchids were never before seen in such fine condition. Vegetables were scarcely up to the usual standard. The entries totalled to five hundred and thirty five, and high quality as well as quantity was apparent on every hand.

Mr. Francis Nicoll, Craigclowan, Perth, won the leading honours for a table of orchids in which odontoglossums and dendrobiums figured largely; Mr. Malcolm McIntyre, gardener to Sir C. Tennant, a good second. Mr. M. McIntyre, who was the leading prize-winner throughout, won the chief award in the class for a table of plants, the space being a circle twelve feet across; here Mr. McIntyre arranged palms, amaryllis, clivias, orchids, liliums, lily of the valley, &c., in a charming manner; all the plants were well grown, and the prize was well deserved. A silver cup presented by Messrs. T. Smith and Sons, Edinburgh, goes with this first prize. The second-prize winner was Mr. G. Wood, Oswald House, Edinburgh; Mr. J. Cocker, Chesters Hall, Northumberland, third. Mr. M. McIntyre's list of first prizes includes chief awards for ten forced plants in bloom; six stove and greenhouse plants, in flower; three varieties of Azalea indica; six hardy azaleas; six foliage plants, exclusive of palms; twelve cyclamen; two amaryllis; two guelder roses; and six Primula obconica; these he gained in addition to several seconds in the plant classes. Mr. W. Bennett, Hanley Lodge, Gogan, secured first prize for half-a-dozen forced plants exclusive of hyacinths and tulips; Mr. McIntyre coming second. Mr. J. Bald, Canaan House, Grange Loan, was second, and Mr. Bennett third for ten forced plants. Two superb greenhouse rhododendrons secured for Mr. A. Calder, Calderbank, Trinity, a first prize; while for three hardy ferns, well grown in tubs, Mr. G. Chaplin came to the front. Mr. J. Bald and Mr. G. Chaplin, St. Leonards, were first respectively for two and four azaleas. Mr. D. Wilson won first prize for four specimen orchids, and Mr. J. Wood was first for one orchid; Mr. M. McIntyre coming second in each class. Ferns were quite a feature, Mr. J. Wood winning for three distinct exotic species; Mr. J. Pearson, Rockville, for three adiantums; Mr. W. Anderson, Woodcroft, Clinton Road, for six dwarf British ferns; and Mr. A. Pryde, Newington House, for one specimen tree fern with a three-foot stem. Mr. Alexander McMillan, Douglas Castle, who was second for cyclamen, had a fine pair of dracænas and was first for six cyclamen. Mr. S. Abbott and Mr. D. Mackay were the leading prize winners for pot roses, showing good specimens. Mr. J. Cumming, Green Park, Liberton, came to the front for pelargoniums and also for cinerarias, making a good show of each. Well grown and fragrant mignonette came from Mr. A. Brown. Messrs. Reid, Staward, R. Stuart, and A. Paterson were the leading exhibitors and prize winners in primula and polyanthus classes.

Numerous plant classes were provided for nurserymen, these comprising azaleas, rhododendrons, forced plants, palms, conifers, evergreen shrubs, Japanese maples, ferns, table plants, hyacinths, and tulips. The leading prize winners were: Mr. J. Downie, Messrs. R. B. Laird and Sons, Messrs. J. Dickson and Sons, Mr. E. Campbell, Gourock; and Mr. W. J. Watson, Newcastle.

Mr. J. Meiklem, Sunnybank, Bridge of Weir, had the best two dozen hyacinths and the best six in two distinct classes. Mr. Bald, Mr. J. Pearson, and Mr. S. Brydon divided the honours for narcissi and tulips.

In the fruit classes Mr. M. McIntyre was again very successful, winning firsts for a pineapple, six pots of strawberries, and thirty strawberries. Mr. W. Smith, Dalkeith, was first for black and also for white grapes. Mr. J. Cairns showed the best twenty-four kitchen apples in six varieties; Mr. J. Day, Galloway House Gardens, a good second. Mr. McKinlay, Musselburgh, was first for dessert apples; Mr. J. Cairns and Mr. Day following in order.

In the vegetable classes there was a wide distribution of prizes. Mr. W. Harper won for a collection of twelve vegetables, distinct, and for asparagus; Mr. D. Kidd, for leeks and cucumbers; Mr. G. McDougal, for tomatos; Mr. W. Macrobie, Abbey Hill, for mushrooms; Mr. J. Cossar, for French beans; Mr. J. Shearer, for seakale; Mr. W. Henderson, for rhubarb; Mr. W. Galloway, for new potatos and cabbage; Mr. A. Lauder, for broccoli; Mr. J. Laing, Blairgowrie, for onions; and Mr. W. Spence, for carrots and swede turnips.

ISLE OF WIGHT.

THE Isle of Wight Horticultural Improvement Association held its second annual non-competitive exhibition of daffodils and spring flowers at Shanklin on April 2. The opening ceremony was performed by the Lady of the Manor (Mrs. White-Popham), and was well attended.

The exhibits were numerous and of first-class quality. Messrs. Barr and Sons, London, received the association certificate for cultural merit for a magnificent collection of daffodils. They also received first-class certificates for daffodils Duchess of Westminster, Barri Conspicuus, and E. J. Berkeley. Mr. John Gell, St. Lawrence, received the association certificate for cultural merit, for thirty vases of daffodils (Sir Watkin being especially fine). Mr. W. H. Jobling, Spring Hill, E. Cowes, received a similar award for a collection of hardy spring flowers. Mr. F. Woods, Steephill Castle, Ventnor, staged a collection of cinerarias for which he received the association certificate for cultural merit; Mr. J. H. Silsbury, Shanklin, also received a certificate for a collection of daffodils.

Other exhibits of note were palms and dracænas from Mr. F. Silsbury, Clarendon Lodge, Shanklin; a group of miscellaneous plants and flowers effectively arranged from Mr. C. H. Snook, Westhill, Shanklin; a collection of flowering and foliage plants from Mr. S. Banks, Shanklin; cut blooms of tulips from Mr. J. H. Perkin, Los Altos, Sandown; fine seedling amaryllis and large spikes of Iris fimbriata from Mr. W. Tribbick, F.R.H.S., Brooke House, Brooke; and floral decorations from Mrs. A. Carter, Rosendale, Shanklin. The popularity and usefulness of the association is becoming more appreciated, and the attendance was remarkably good. Several new members were enrolled during the afternoon and evening.

SHIRLEY GARDENERS' ASSOCIATION.

THE annual general meeting of the above society was held at the Parish Room, Shirley, Southampton. The President, Mr. W. F. G. Spranger, presiding over an average attendance of the members. The report showed that twelve meetings had been held during the past year, five hundred and sixteen members attending, giving an average per meeting of forty-three. The attendance it was felt should average more with a membership of one hundred and forty. The accounts showed a balance of £3 odd in favour of the association with some still to come in. The president, vice-presidents, treasurer, and secretary, were re-elected, and a committee of fifteen were balloted for. A most sincere and hearty vote of thanks was accorded to the President, and also to the horticultural and local press. Some of the members and their friends then gave a pleasing entertainment, which was very much appreciated by those present.

THE WEATHER DURING THE WEEK ENDING APRIL 9, 1898.

The direction of the wind was variable, the horizontal movement of [illegible] 12 per cent. above the week's average in the 16 years 1860—75. The duration of [illegible] sunshine in the week was 47·8 hours. The measured rainfall amounted to [illegible]

CATALOGUES RECEIVED.

Barr and Sons, Covent Garden.—Hardy Perennials and Alpines.

H. Cannell and Sons, Swanley, Kent.—Floral Guide for 1898.

ANSWERS TO CORRESPONDENTS

Editorial communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Revolution in Chrysanthemum Culture.—G. C. J., Hitchin: You will find your query answered in the present issue under the heading of "Dwarfing Chrysanthemums."

Bamboos—M. H. W. Walkley: The work to which you refer is "The Bamboo Garden," by Mr. Freeman-Mitford, of Batsford Manor. The book is published by Messrs. Macmillan and Co.

Botanical Names of Popular Flowers.—C. O. S., Hertford: The following are the correct botanical names of plants recognised by the popular names sent. Scarlet Monkey Flower, *Mimulus cardinalis;* Sassafras tree, *Laurus Sassafras;* Pasque-flower, *Anemone Pulsatilla;* Sweet Woodruff, *Asperula odorata;* Wallflower, *Cheiranthus Cheiri;* Mint, *Mentha viridis;* Liquorice, *Glycyrrhiza glabra;* Liverwort, *Marchantia polymorpha;* Dogwood, *Cornus sanguinea;* Hemlock, *Oenanthe crocata;* Goldielocks, *Chrysocoma Linosyris:* None-so-pretty, *Saxifraga umbrosa.*

Potting Caladiums.—F. W., Derby: You should pot on the caladiums whenever necessary to produce large and well-grown specimens until a reasonable time before the exhibition, or until foliage production ceases. Equal parts of leaf-mould, fibrous loam, and dry cow manure, with a little peat and sand added, make a first-rate compost. If the size of pot is limited, or it becomes apparent that further potting will answer no useful purpose, then liquid manure should be afforded all well-rooted examples. Scarcely any shade is necessary, save for a day or so after potting. Maintain a moist atmosphere and treat the plants liberally in every way.

Pinching Chrysanthemums.—R. S., Colchester: Joseph Chamberlain and Mary Molyneux are distributed this season for the first time, so that it is not possible to advise on the special treatment of these without experience of their growth. The distributor of the first named (Mr. Davis) says in his catalogue that J. Chamberlain "is an easy doer on crown bud," and we believe Mary Molyneux will be best from natural second crowns; if this variety does not show a "break" bud by April 25, try pinching one plant then, and allow another to grow on to the natural break. They both appear to be strong growers. Pinch Mrs. F. A. Bevan and Mrs. S. C. Probin at once (should have been done by April 7), and take second crown buds; both these are liable to damping of the blooms, and though they should be well grown be careful not to feed with strong manures late in the season. Western King is best from buds about August 20 to 25; if your plants are strong and forward pinch April 20, and take second crowns; late or weakly plants will probably not show their crown buds too early, and need not be pinched.

Stopping Chrysanthemums—W. B., Otley: The query comes somewhat late. The following are the dates, according to Mr. Lees. Nos. 6, 7, 9, 11, 14, 15, 18, 20, 21, and 30, should be all right if ordinary crown buds are taken. Nos. 1 and 2 are rather uncertain in bud formation; secure a bud as near August 20 as possible. Pinch No. 5 about March 10, and take second bud on ordinary crown. Nos. 4, 8, 10, 19, 22, and 27 take second crowns. Strike No. 28 about the end of January; take crown bud, it comes early. Pinch Nos. 3, 16, and 29 April 10, and take crown buds. Pinch Nos. 23 and 26 on April 18, and take crown buds. Nos. 13, 24, and 25 not grown; No. 12, no use.

Globe Artichokes.—H. L., Hendon: New plantations of globe artichokes should be made this month, choosing for the purpose a plot of well-worked rich soil that is moist though well drained. Place the clumps about four feet apart each way, or the rows four feet apart and the plants three feet apart in the rows. Choose strong suckers, but not those that are at all woody. Remove the large outside leaves and plant the suckers about half their depth in the soil. Some gardeners remove and pot up the suckers as they are ready, and keep them in a well-aired cold frame until planting time. Good waterings will be necessary to ensure establishment, while a seakale pot for each plant will be useful to ward off brilliant sunshine for a week or two, and also to afford some protection from severe frosts should such occur.

Doronicum plantagineum for Forcing.—R. C. F., Guildford: This plant should be divided every year, and replanted in rich soil, if good specimens for early flowering be desired. It does not require forcing, in the general acceptation of that term. Lift a few examples during late autumn, and pot them up, afterwards standing them in a cold frame. If kept free from frost, and watered as they require moisture, they will come into flower early, and prove most useful for conservatory decoration during February. The large bright golden yellow flowers are also extremely useful for cutting, and for this purpose alone a good batch would prove useful in any garden. After flowering, turn the plants out of their pots, divide, and plant out in rich ground; water freely if the weather be dry, and they will be ready for potting again in the autumn.

Hoya bella.—M. C. G., Romford: The requirements of Hoya bella are a light porous soil and a well-drained pot or tub. The compost should consist of fibrous peat, loam, and leaf-soil, mixed with an abundance of mortar-rubbish or sand and finely broken crocks. From August until February very little water is needed, and during the winter a temperature of 55 degrees will suffice. The best time to repot or plant out this Hoya is during February or early March; the warm greenhouse will prove a suitable home for it, and we should not hesitate to pot at once rather than badly starve the specimen. If placed against a brick wall the Hoya needs little support, as it emits rootlets from the stem which cling to the rough surface. Hoya bella comes from Taung Kola, and was introduced in 1847. The genus was named after a Mr. Hoy, who at one time was head gardener at Syon House, Brentford. The hoyas are popularly known as Honey-flowers.

Nitrogenous Manures for Potatos.—B. K., Cambridge: Either sulphate of ammonia or nitrate of soda are excellent nitrogenous manures for potato cultivation if given as top-dressing. The former, if a good sample, should be used at the rate of 1½ lb. per rod, this amount being applied in three dressings of half a pound each, at the first hoeing, first earthing, and final earthing up; these latter operations take place approximately at the middle of May, beginning of June, and middle of June. Nitrate of soda may be applied at

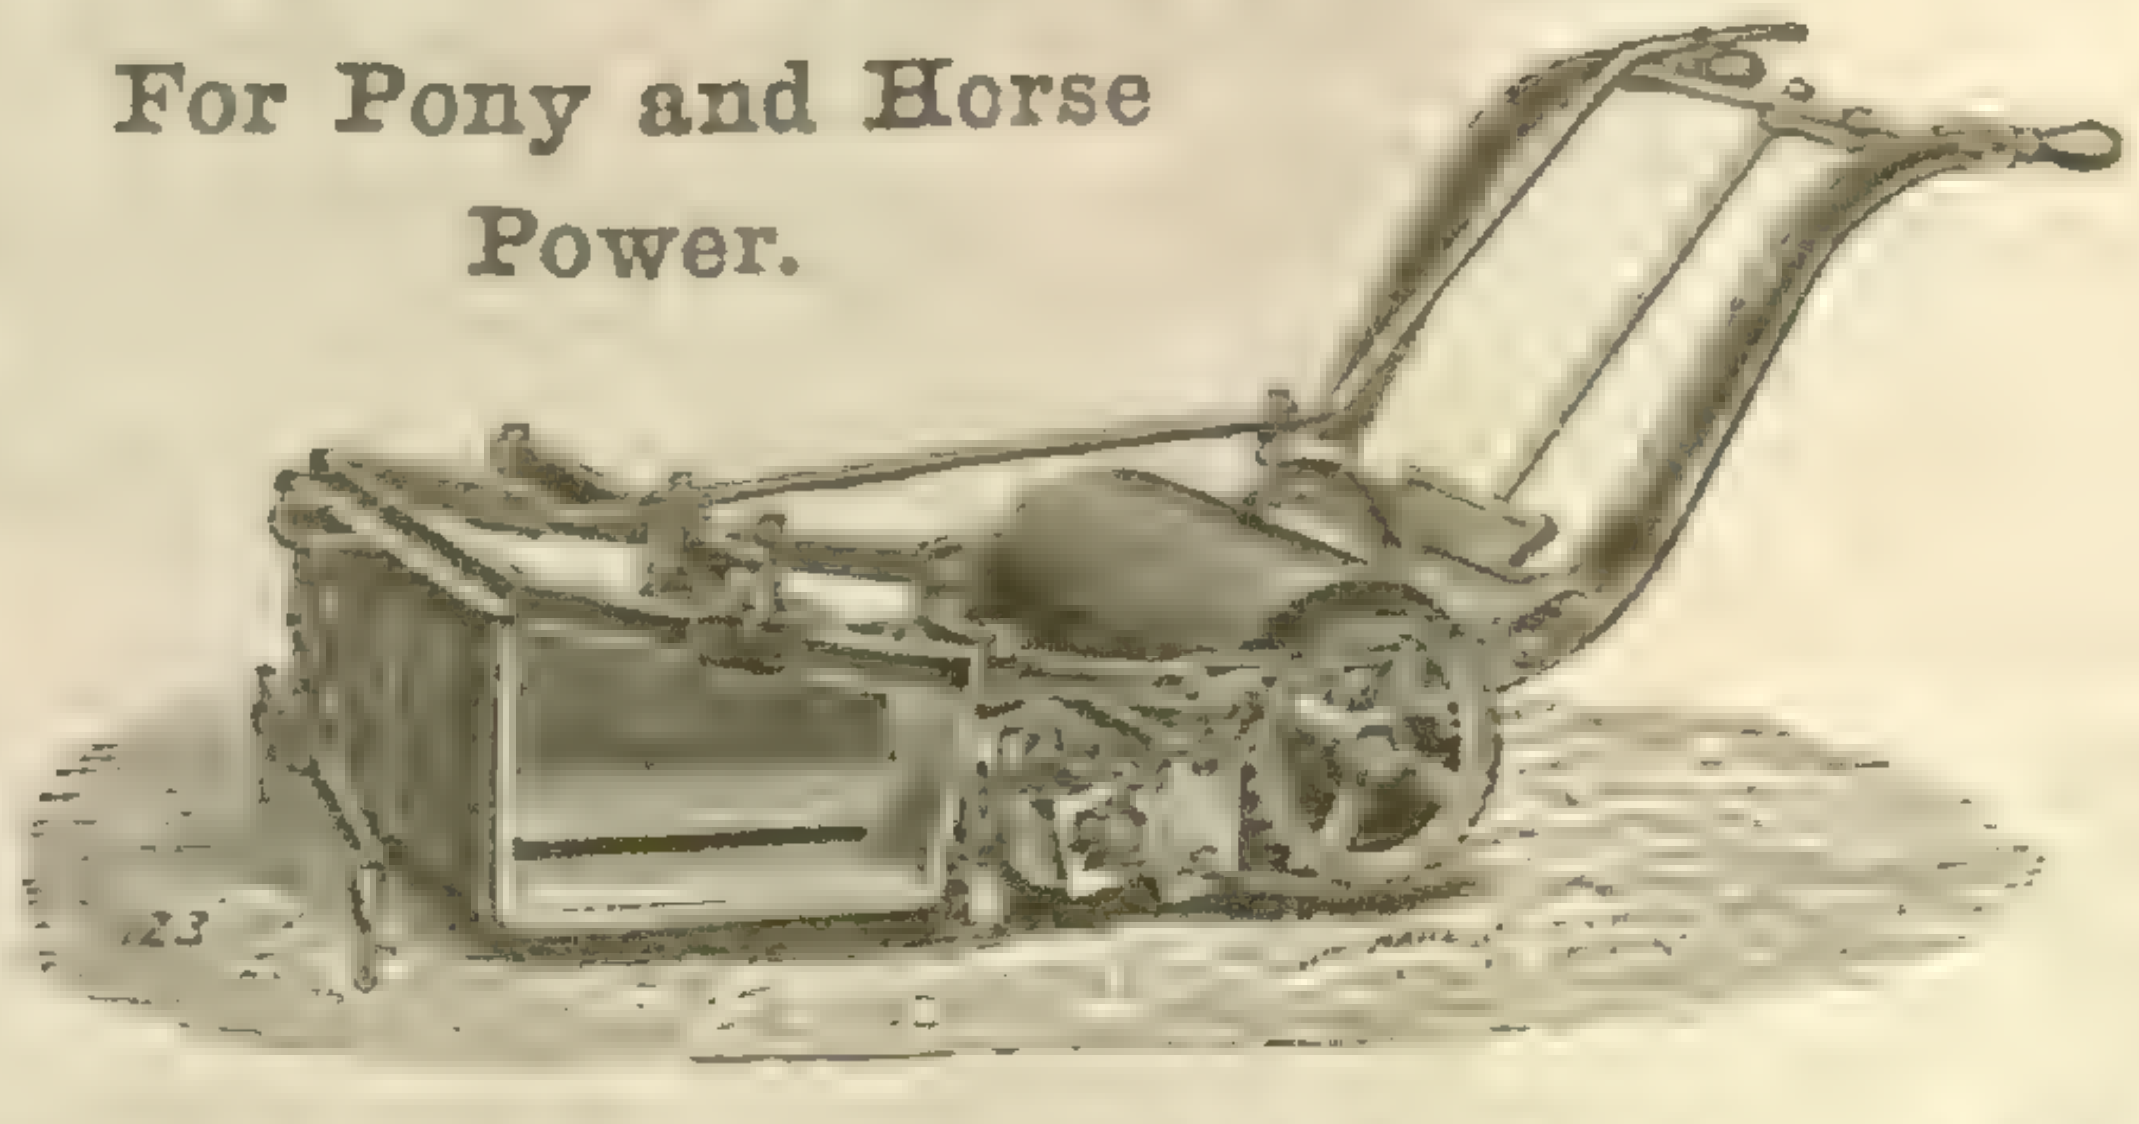
All the hand-power sizes (except the 8-inch) are fitted with the patent height regulator.

"GODIVA" LAWN MOWERS.

For Pony and Horse Power.



Sent direct from works, carriage paid, to any railway goods station in England or Wales.

These large machines embody all the leading features of the hand-power "Godiva" Mowers, and they are strongly recommended by the makers as the latest in design and best in the market. The improved lever side delivery, which delivers the cut grass at either side, is a most valuable adjunct. Sizes from 24 inches wide up to 42 inches.

BENETFINK AND CO., CHEAPSIDE, LONDON, E.C.

the rate of 2 lb. per rod, as its value as a nitrogenous manure compared with sulphate of ammonia is as three to four. It is, however, a quick-acting manure and especially valuable on light soils. The 2 lb. should be divided into three equal parts, and one of these used on the three occasions before noticed. Both these manures are only of advantage when the land is in good condition otherwise. We have used both on land of medium texture and good condition, and have found scarcely any difference in the resulting crop, though the soil does not seem so used up after sulphate as after nitrate. If your land is very light use nitrate of soda, as it tends to keep the soil moist.

Names of Plants.—M. E., Ripon: 1, Clivia miniata, also known as Imantophyllum miniatum; 2, Cyperus alternifolius; 3, Yucca aloifolia lineata-lutea; 4, an abutilon, send when in flower.

C. C., Calville: The yellow-marked leaf is Cineraria maritima aureo-variegata; the other specimen is probably Gazania ringens, but it was too much damaged to allow of certain identification. See rules as to sending plants for naming.

J. D., Garliestown: Bifrenaria Harrisoniæ, known in some gardens as Maxillaria Harrisoniæ.

WEST'S
PATENT
IVORINE
PLANT LABELS
NAME TO BE WRITTEN ON WITH ORDINARY LEAD PENCIL OR PEN AND INK.

THE "IVORINE" WRITING DISC, Being made of a specially prepared substance, having the properties of real ivory, is imperishable, and does not corrode or eat away, like wood and metal labels; and being ivory-white, when written upon it shows to perfection. And also, as the writing is on the Ivorine itself it is permanent, hough washable, and does not become unreadable, as is the case with all painted labels, as the paint gets old. It is for all purposes, and will last a century, either in a greenhouse or out in a garden, and not only is it always ready for use, and may be written on both sides, but the name when written in pencil may be easily rubbed off, and so used as many times as desired.

Samples and Lists of the West's Patent Specialities post free.
Price, **9d.** per dozen; **8s.** per gross, Carriage Paid.

NATIVE GUANO.

BEST AND CHEAPEST MANURE FOR GARDEN USE.

Price **£3 10s.** per ton in bags. Lots under 10 cwt., **4s.** per cwt., 1 cwt. sample bag sent carriage paid to any station in England on receipt of P.O. for **5s.**

Extracts from 22nd annual collection of reports:—

NATIVE GUANO FOR POTATOS, VEGETABLES, &c.
C. H. TINDALL, Bardney: "Used for Potatos. Result very satisfactory; yield much above average. A splendid manure." G. WATTS and SONS, Bournemouth, report: "Good for general purposes. Grand for all Root Crops, Tomatos, and Cucumbers. Find it so cheap; and it does not exhaust the ground like other manures."

NATIVE GUANO FOR FRUIT, ROSES, TOMATOS, &c.
E. F. USHER, Sidcup: "Potatos and carrots, splendid crops; Peaches, Nectarines, &c., splendid. Should not like to be without it on any consideration." G. STONARD, Gardener to Sir A. T. Watson, Bart.: "Used for seven years for Peaches, Grapes, Tomatos, Cucumbers, Roses, and Chrysanthemums with excellent results."

Orders to the **Native Guano Co. (Limited)**, 29, New Bridge Street, Blackfriars, London, where pamphlets of testimonials, &c., may be obtained. Agents Wanted.

"Whart House, New Mills, Derbyshire, April 4. 1898.

"GENTLEMEN.—Just a line to say that I have lent your 1898 Catalogue to Dr. Chapman, of this place, who has recently built a greenhouse, and have strongly recommended him to send his orders to you. I have told him all that I had from you has been far and away better than what I have had from any other source, and I have decided never to get anything more from anyone but you. He has seen my place and is much pleased.—Yours truly, J. SWINDELLS."

SWANLEY, KENT.

A NEW AND REVISED EDITION. **Price 6/-**

Crown 4to., cloth, gilt edges. *Illustrated with numerous Engravings, Page Plates, and Coloured Frontispiece.*

RUSTIC ADORNMENTS FOR HOMES OF TASTE.

By the late SHIRLEY HIBBERD.

CONTENTS.

Homes of Taste,
Floral Decorations.
The Fern Case.
The Balcony and Window Garden.
The Amateur Propagator.
The Greenhouse and Conservatory.
The Fern House.
Pleasure Garden,
Flower Garden.
Rockery.
Fernery,
Garden Aquarium,
Summer House.
Embellishments.
Marine Aquarium.
Fresh-water Aquarium.
Aviary,
Apiary.

The work, as originally published, met with considerable favour, and several editions were produced and published within a short time. The edition now in preparation will follow, in the main, the lines of the original volume as written by the late Mr. Shirley Hibberd, as much as possible of his work being preserved, and alterations made only with a view to bringing the treatment of the various subjects up to date in every respect,

W. H. and L. COLLINGRIDGE, City Press, 148 & 149, Aldersgate Street, London, E.C.

A REVOLUTION in Chain-Driven LAWN MOWERS!

THE NEW PATENT

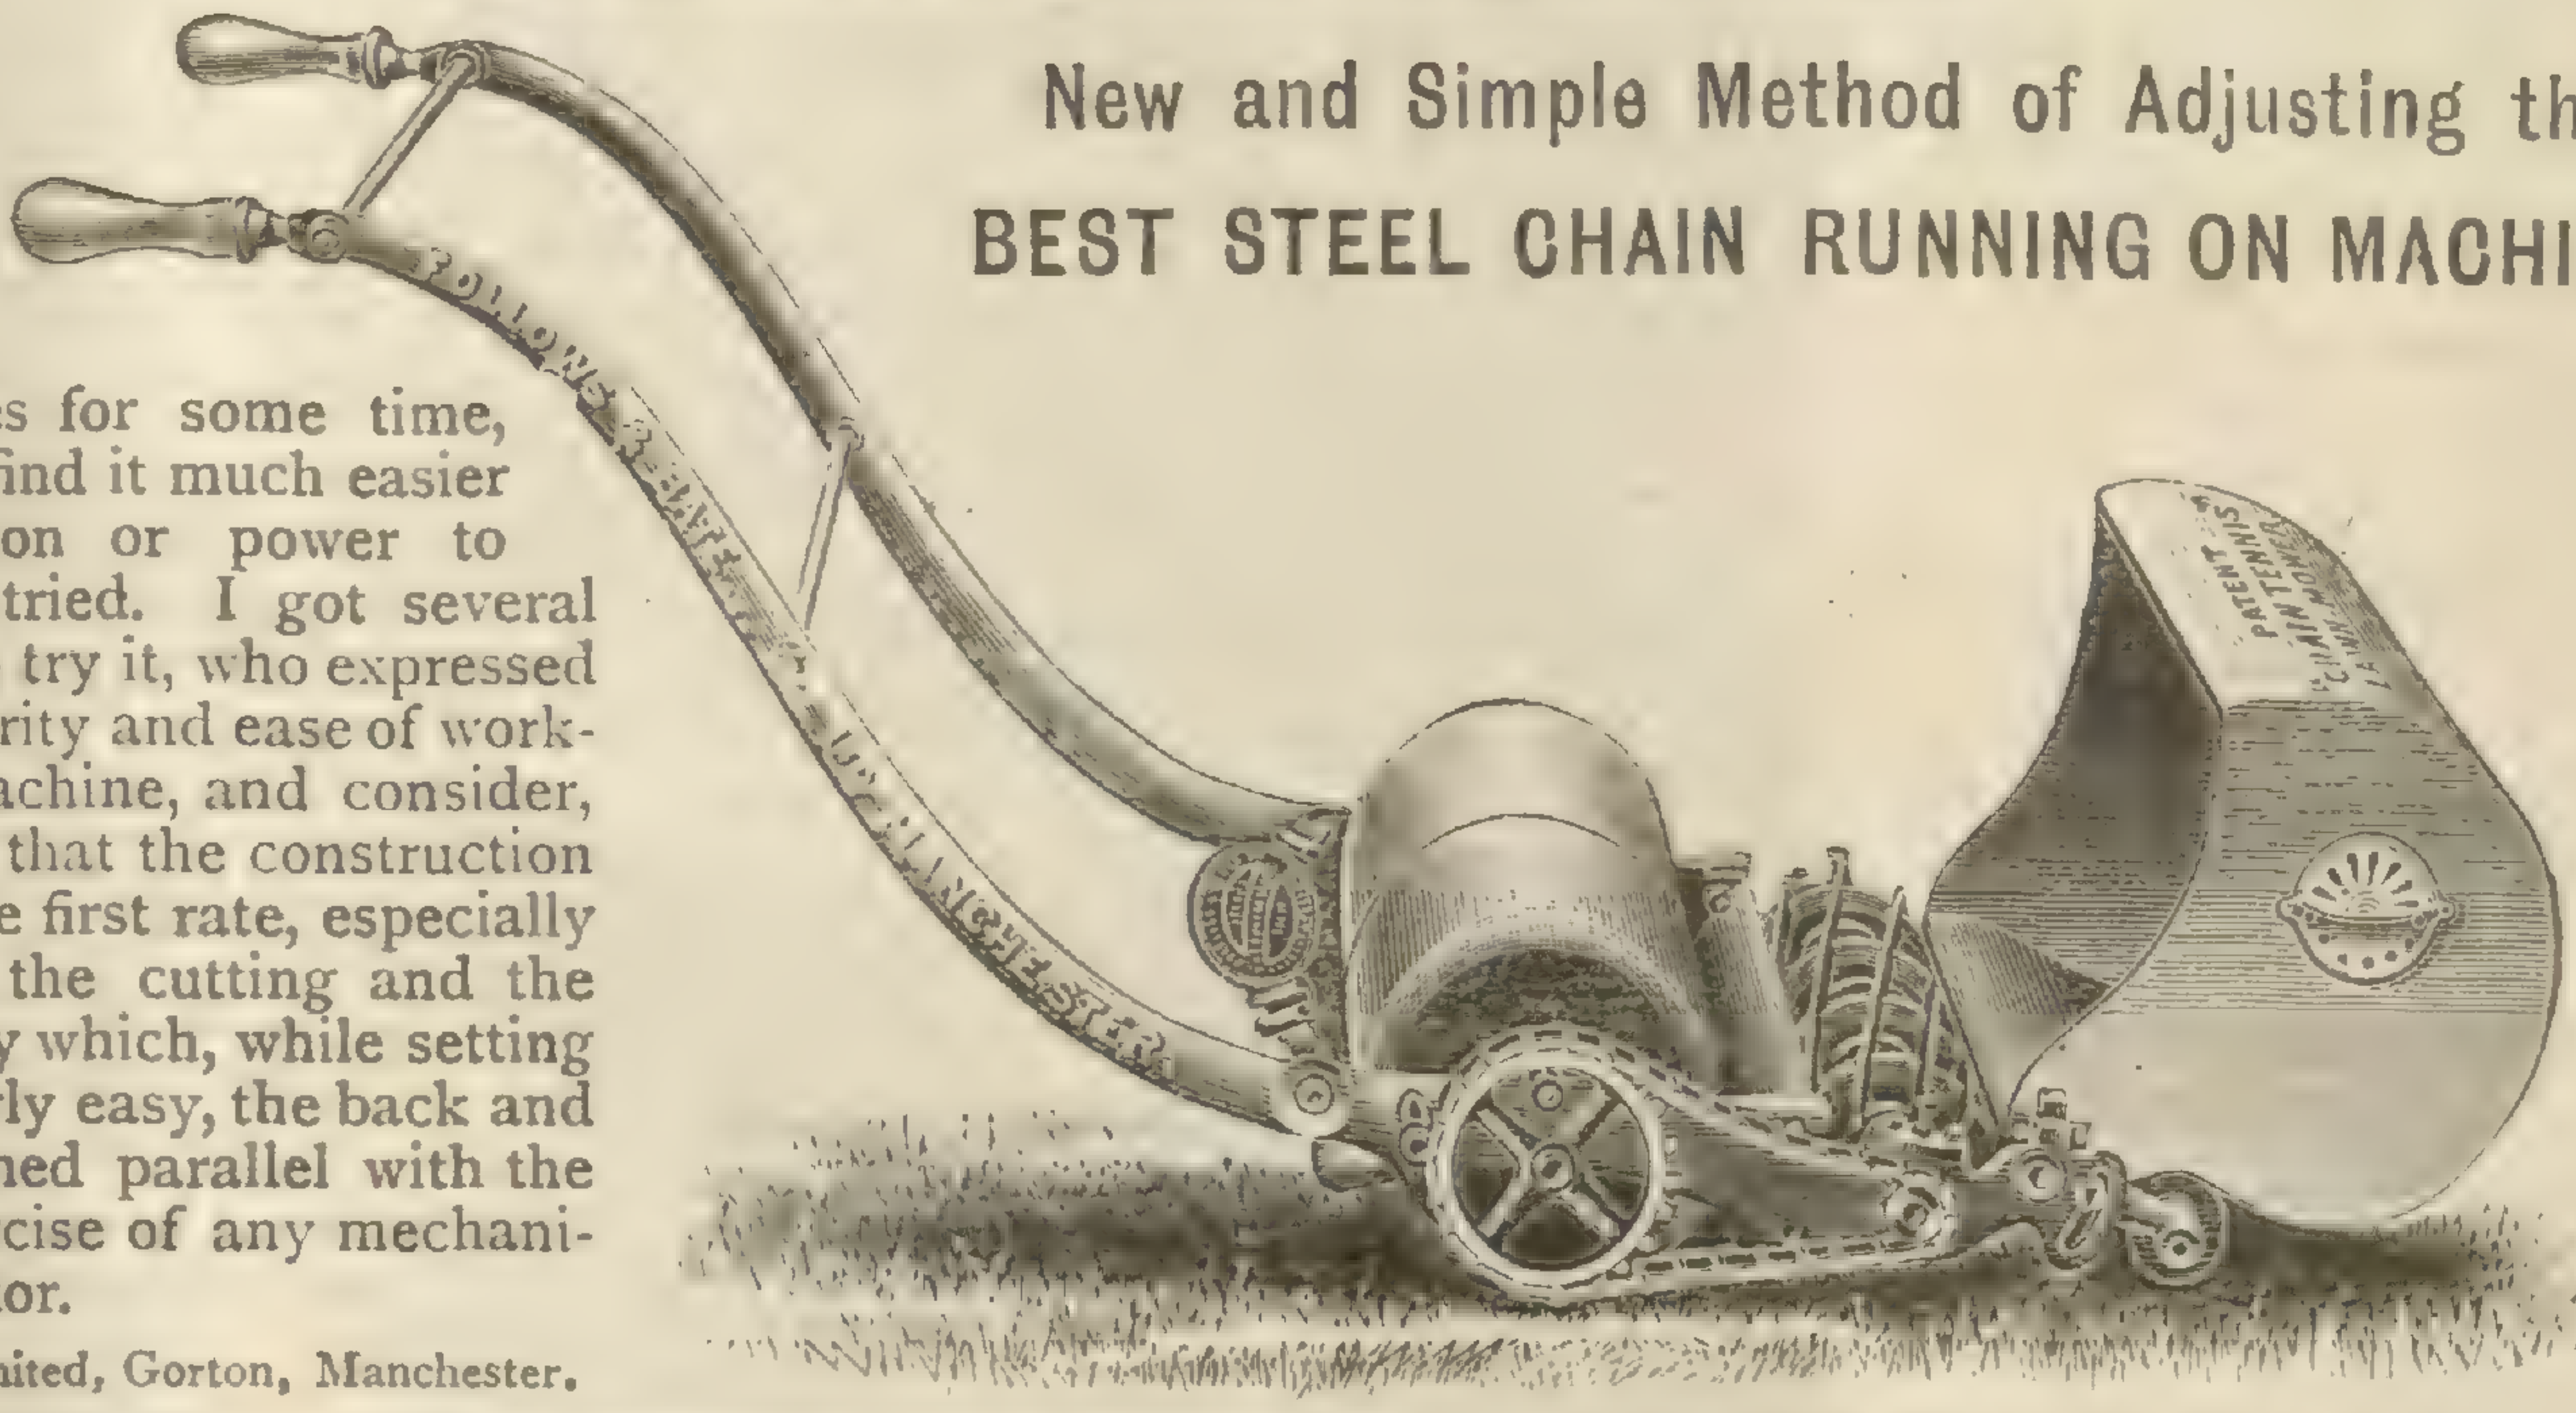
"CHAIN TENNIS" LAWN MOWER.

THE LATEST AND BEST CHAIN MACHINE. FITTED EQUAL TO A HIGH-GRADE BICYCLE.

TESTIMONIAL FROM
J. OWDEN O'BRIEN, Esq.,
M.I.M.E.
March 21st, 1898.

GENTLEMEN,—I have now had one of your 12 in. Chain-geared Lawn Mowing Machines for some time, and have personally tested it. I find it much easier to work, *i.e.*, takes less exertion or power to drive, than many others I have tried. I got several working or practical gardeners to try it, who expressed the same opinion as to its superiority and ease of working. I have also examined the machine, and consider, from a mechanical point of view, that the construction and arrangements of the parts are first rate, especially in reference to adjustment of the cutting and the tightening of the driving chain, by which, while setting of the parts is rendered particularly easy, the back and front rollers are always maintained parallel with the cutting cylinder without the exercise of any mechanical skill on the part of the operator.

To Messrs. FOLLOWS and BATE, Limited, Gorton, Manchester.



New and Simple Method of Adjusting the Chain and Cut.
BEST STEEL CHAIN RUNNING ON MACHINE-CUT WHEELS.

SIZES—
10 in., 12 in., 14 in., and 16 in.

WRITE FOR PRICE LISTS.

To be obtained from all leading Ironmongers and Seedsmen, or, if any difficulty, from the Makers,

FOLLOWS and BATE, Ltd., Gorton, MANCHESTER.

Sold by all Chemists, price 2s. 9d. per bottle.

DOBBIE & Co.'S ANNOUNCEMENTS.

DAHLIA PLANTS.

WE are now busy sending these out to all parts of Britain, and to many continental countries. Those who have not already ordered, and who are desirous of having Dahlias early in bloom, should send in their orders at once. When received (in Neponset paper flower-pots if desired with balls of soil whole), they should be potted into 4-inch pots in nice, rich, open compost, and grown on for two or three weeks in a warm house or frame, afterwards gradually hardened off, and planted out 1st June This is the way to obtain plants which will begin blooming in July.

We grow the best, and only the best, varieties in all the different sections—

Show and Fancy, True Cactus, Decorative, Pompone, Single, and **Single Cactus,**

and offer our Selection at the uniform price of

5s. per dozen (in Neponset pots, 5s. 6d.), carriage paid.
35s. per 100 (in Neponset pots, 38s.), carriage paid.
(In not less than 50 varieties.)

Buyers wishing to make their own Selections can have Catalogues on application.

THE DAHLIA: Its History and Cultivation.
A Handbook for all Growers.

The *Leeds Mercury* says: "With the aid of this pretty illustrated volume the cultivation of this superb flower should present no difficulties to anyone." Price, in stiff paper covers, 1s.; in cloth boards, 1s. 6d.; post free.

EARLY-FLOWERING CHRYSANTHEMUMS.

Our Collection is one of the Finest Extant.

Fine plants, ready for planting in the open border. Will bloom from July onwards. Our Selection—12 plants for 3s., 25 for 5s. 6d., 50 for 10s., 100 for 17s. 6d. Carriage paid. A trial order for these is particularly solicited.

"Flowers in Season.—Some glorious bunches of Early-Flowering Chrysanthemums reach us from the Scotch Nursery of Messrs. Dobbie and Co, at Rothesay. They are all very beautiful, and no plea for their cultivation need be urged when they afford such flowers from an open field so late as October 8."—*Gardeners' Chronicle*, 16th October, 1897.

PELARGONIUMS.

Fine Plants. Splendid Value.

12 **Grand Single Varieties**, post free for 4s. 6d., 6 for 2s. 6d.
12 **Grand Double Varieties**, post free for 4s. 6d., 6 for 2s 6d.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at One Shilling per line, the minimum charge being Five Shillings. Advertisement Office, 148 and 149, Aldersgate Street, London, E.C.

NOTICE TO ADVERTISERS.

Owing to the continued increase in circulation, the "Gardeners' Magazine" now goes to press on Wednesday. No advertisement can be guaranteed insertion, or altered, unless received before Four p.m. on that day.

NOTES OF THE WEEK.

THE GHENT QUINQUENNIAL.

THE special report of the horticultural exhibition that is now in progress at Ghent, which we give in the present issue, will enable those of our readers who were not present to obtain an adequate idea of the general scheme, and enable them to determine with some degree of exactitude the chief points on which it differs from the horticultural exhibitions held in the United Kingdom. It will be seen that it exceeds in extent the largest of the gatherings that have taken place in this country since the great international exhibition held in 1866, and that due regard has been paid to the grouping of the multifarious subjects with a view to the production of artistic effect. In this respect it presents a marked difference from the exhibitions held at home, and as an object lesson in the tasteful arrangement of plants at public exhibitions it should prove of immense value. Whether full advantage will be taken of the lesson remains to be seen, but the prospect is not hopeful, for in but few instances does there appear an active desire on the part of those responsible for the arrangement of our flower shows to present to the public the material at their command in the most attractive manner. To adopt a scheme similar to that formulated at Ghent is under ordinary circumstances impossible, because of the large space required and the heavy expenses that would be involved in carrying it out. Much, however, might be accomplished in rendering our exhibitions more attractive than they usually are, and we should be pleased to see a serious attempt made at the Temple Shows to follow the example of our Belgian friends. We are perfectly aware that it cannot be closely followed; but the larger tents might be rendered less monotonous by the more liberal use of stately palms and tree ferns. The great features at Ghent are the azaleas, hardwooded greenhouse plants, the palms and cycads, and stove plants grown for elegance of aspect or the attractive colouring of their foliage, and these are, with some other features, immensely attractive. We, however, miss the hardy flowers, the alpines, the miscellaneous plants, and the fruits and vegetables, which contribute so materially to the attraction and interest of British exhibitions; and also the glorious display of orchids that proves so great an attraction of the Temple Shows, and to this extent the Ghent Exhibition suffers in interest. Of the judgment, the good taste, and the energy displayed in carrying out the Ghent Quinquennial it is impossible to speak too highly, and more particularly deserving of praise are the Comte de Kerchove, the president of the society; M. Ed. Pynaert, who was responsible for the arrangements; and M. Fierens, the courteous secretary, who at the [illegible] gatherings were heartily congratulated on the splendid results of their well directed labours.

PLANT DEFENCE.

THE very interesting paper on Cinchona by Mr. J. A. Gammie recently published in these pages dealt exhaustively with the marvellous developments which have been effected by cultivation upon the quinine elements of the bark of the cinchona tree, and its consequent increased value to mankind. Nature, however, in the evolutionary creation of the cinchona plants undoubtedly endowed its little cells with the power of fashioning the intensely bitter active principle known as quinine for its own particular benefit, and not that of man, so that here, as in innumerable other cases, its virtues as a tonic and febrifuge appear to be altogether outside its *raison d'être*, regarded from the human point of view. Knowing, as we do, what a host of tree foes may find harbourage in the bark, or bore through it and prey upon the vital tissues immediately beneath it, not unfrequently inflicting mortal injuries, it is reasonable to assume that a bitter acrid principle, such as quinine, would constitute a most effective protection against the borers, and probably the other vermin as well. Such protection, however, can only be due to actual bitterness, and though it is a curious fact that this bitterness seems correlated to some extent with tonic and febrifugal qualities, these latter can hardly have figured in any way in the evolutionary development of cinchona, since if the boring insects are subject to any diseases curable by such agency, they would have been encouraged rather than deterred by such medicinal aid. In this particular connection it would certainly be of intense interest to know how far trees, whose wood or bark possesses pronounced medicinal powers, enjoy immunity from vermin, boring or other. The bark of a tree, as everyone knows (save the bark-cutting vandals who mutilate our suburban avenues), is of vital importance. We may lop and prune the branches, and even cut down the trunk to the ground without destroying life altogether; buds will be left, and these in time will reinstate the growth, but if we cut out a ring all round the bark, the tree is usually killed. The active life of a tree, the circulation of its sap, the interchange of vital materials supplied by the roots on the one hand from the moisture and salts of the earth, and by the leaves on the other from the nutrient gases of the air, is all carried on in the thin strip which lies between the bark and the last ring of wood formed by the previous year's growth. The old wood does nothing but supports the mass of growing branches and leaves, all the life work goes on in the slender zone described. Sever this, then, and we see at once the tree must be paralysed, and also know the reason. This being the state of affairs, it is clear that evolution must have done much to strengthen the protective nature of this vital armour, and it is a curious branch of botanical study to examine in how many and varied ways these armour plates are strengthened to meet the offensive tactics of the foe, whose weapon or habits are simultaneously varied to strengthen their attacks, precisely as the two branches of our war department are ever active in devising more powerful missiles and stronger resistants. In cinchona bark, however, we presumably bring in a different factor; and just as the calm and dignified Oxford professor parted with a deftly administered pinch of snuff, two bulldogs which a whole party of students were vainly trying to drag asunder by main force, so a small percentage of quinine deftly distributed through the cortical tissues probably baffles the stoutest borer that even the tropics can produce, by drastic effects upon its palate, and, may be, its constitution also.

THE PLEASING PRIMULA.

So we translate that handsome form which was originally known as P. cortusoides amœna, but now generally recognised as P. Sieboldi. It is a species that will remain associated with the name of John Gould Veitch as one of his discoveries in Japan. The type P. cortusoides had long been known to us; but in Sieboldi there is seen such a marked advance in the size of the blossoms and the vigour of the foliage, that it is not surprising it was at first regarded as a valuable new species. After it had been some time in cultivation, it was found that the honour of having first discovered it belonged to Siebold; hence the later specific name. The original form as introduced, and still in cultivation, is represented by a bright rosy crimson saucer-shaped flower, with smooth edges. Later introduced varieties were the white, having a limp and ill-developed corolla fimbriated on the edges; the rose and white smooth edged, named grandiflora; and a lilac-coloured type named lilacina, so distinct from the others, having a well-expanded and flat corolla, at that time so distinct and altogether unique in character as to rank as a true species. Beautiful and interesting as these charming primulas were, they did not call forth so much enthusiasm as their later and less worthy relative P. japonica did when introduced later in time. It appears strange, but it is nevertheless true, that these fine forms of P. Sieboldi were in cultivation in this country for a considerable time before any steps were taken to cross fertilise them, but it was done about the same time by Mr. James Allen, at Shepton Mallet; Mr. A. Dean, at Bedfont; and M. Victor Lemoine, Nancy, France; and from that time onward new varieties have put in an appearance, showing a wide range of colours, shades of blue having been met with in the case of the common primrose. But despite their beauty their variety, freedom of bloom, and the readiness with which they lend themselves to cultivation, they are by no means generally cultivated, though they bloom in April and May. The species and varieties raised from it are deciduous hardy perennials, having creeping rhizomatous roots, which spread themselves below the surface of the soil in which the plants are growing, and soon form large clumps, which are capable of division, and thus a variety can be largely increased. It is a plant impatient of too much moisture in the soil, and when planted out permanently should be on rock work, where moisture can readily pass away from the roots, for it is stagnant water which is so harmful, especially so when the plant is at rest. It is usual to grow this species in pots, dividing the roots in the autumn, or at the end of the winter. Every eye will make a plant, and one or more can be placed in a small pot of suitable soil, and if given protection from frosts, there is soon made small flowering specimens, and it has now become the practice to exhibit the various varieties in boxes or baskets, standing a number of small plants in each, and so forming dense masses.

Blights and their Parasites.—Without doubt in selecting as the title of his recent lecture at the Drill Hall "Blights and Blessings," Mr. Enoch, the able entomologist was rather more alliterative than exact, yet those who heard his singularly interesting and beautifully illustrated address could realise that in referring to blights and blessings he was but conveying the thought dominant all through that if we are as gardeners cursed with blights, the blights are, for our good, equally cursed with destroyers. A good title would have been "Insect Banes and Antidotes." Very interesting indeed was it to learn of some of the parasites which seem in their turn to do so much to feed upon and destroy the insects which primarily feed upon vegetation. There is, for instance, the grub or caterpillar of the wasp fly. This is a creature little regarded, but those familiar with it recognise that its somewhat long body with gold and black markings make it to resemble the water wasp. Possibly for that reason it generally gets wantonly destroyed. Yet this same fly will deposit its egg on the underside of a leaf, and evidently always on a leaf infested with aphis. Shortly it becomes a caterpillar, and thence it proceeds to eat up the aphis. Unlike the ladybird, which seems chiefly to use the aphis as milch cows, feeding upon the sweets they secrete, this wasp-fly caterpillar destroys the feeding insects. It is strictly vegetarian at second hand, for the blight insect feeds upon the vegetable leaf, and the caterpillar the insect. Erecting itself on its posterior, perhaps perched on the ridge of the leaf midrib, it darts its head at the insect, lifts its high up, sucks it dry, leaving only a white skin, and then proceeds to devour another, and so it goes on at a rapid rate, destroying the blight wholesale. Mr. Enoch's moral is that gardeners should get some knowledge of entomology to enable them to distinguish insect friends from their insect foes.

Earlier Opening of Kew Gardens.—This question received a full share of attention in the House of Commons on Monday. In the course of the discussion on the vote to complete the sum of £115,000 for the maintenance of the Royal Parks and Pleasure Grounds, Mr. Akers-Douglas said with reference to his decision to open the gardens at an earlier hour in June next, and the two following months, there never had been a difference of opinion as to opening the gardens at an earlier hour subject to two conditions—that the gardens would be taken advantage of by the public; and, secondly, that it would be safe in the interests of science and the students at Kew to grant an extension. It had at length been decided to open the gardens on June 1 at 10 a.m., and to open them at that hour every morning for the following three months. If it was found that the public appreciated the new arrangement, and visited the gardens to the extent that the advocates of the earlier opening of the gardens said they would, the Office of Works would make the extension of hours—as far as the summer months went—permanent. The Queen's Cottage would be handed over by the Lord Chamberlain's Department to the Office of Works on June 1, and, as soon after as the Office of Works could make the necessary arrangements, the grounds would be opened to the public. It was the intention to preserve the grounds as far as possible in their present condition. They would only open a path from Kew Gardens to the cottage. The rest would remain much in its present condition. It would not be cut up unnecessarily, and it should still form one of the most beautiful bits of wild country in the proximity of London, and be, as it certainly had been, a sanctuary of all bird life in the district.

Rating of Market Gardens and Nurseries. — Our readers will remember that in a recent issue we referred at length to the decision of the Court of Appeal which reversed the decision of the lower Courts in the case of Smith and others v. Richmond. As the higher finding results in market gardeners and nurserymen failing to participate in the relief given under the Agricultural Rates Act of 1896, it is but natural that those most interested should endeavour to obtain a reversion of the Court of Appeal's decision. To do this means a large expense, and carrying the case to the House of Lords for a final settlement; and provided those affected will let Mr. G. Munro, of Covent Garden, know what help they will afford the Market Gardeners, Nurserymen, and Farmers' Association, the latter body will take the matter in hand if sufficient funds are forthcoming, so that there is the prospect of a most interesting struggle.

Sweet Scented Flowers and Fragrant Leaves form an excellent combination, and the lecture on them to be given by Mr. F. W. Burbidge at the R.H.S. meeting on Tuesday next should be of exceptional interest.

Ghent Quinquennial Exhibition.—The illustrations accompanying our report of the Ghent exhibition are reproductions of photographs specially taken by Messrs. B. Jacobs and Co., photographers, of Ghent.

A Remarkable Allium from Western Asia, and one that flowered at Kew last summer, is Allium Schuberti. It is a strong-growing species, with scapes about a foot high, and bearing heads of rosy flowers; sometimes as many as two hundred, each with a long pedicel, are grouped together. This should prove a plant of horticultural merit; it bears the name of its discoverer, and has been introduced by Messrs. Herb and Wulle, Naples. In addition to the foregoing, three other interesting plants are figured in the current issue of the *Bot. Mag.*, and these are Myosotis dissitiflora Dyeræ, a robust free-flowering forget-me-not, forwarded to Kew by Mr. E. J. Lowe, F.R.S., Shirenewton Hall, Chepstow, and named after the wife of the director of the Royal Gardens; Crocus Malyi, a native of Dalmatia, spring flowering, and with large white flowers, having yellow throats; and Rheum ribes, a handsome rhubarb, with green and red flowers, and large blood-red fruits.

A Botanic Garden at Aberdeen is likely to be founded and commenced at an early date, for we are informed that Miss Cruikshank, sister of the late Dr. Cruikshank, has offered £15,000 to the Aberdeen University for the provision of such a garden in memory of her brother.

Surfacing Flower Beds.—Mr. George Wilson, F.R.S., sends the following interesting note relating to covering the verdure during the winter months: Some time back I recommended covering beds with the evergreen sedum, a bit of which I enclose, and dotting bulbs singly about it. I have now carried this out on a large raised bed at Oakwood, using bulbs having blue flowers, such as Chionodoxa gigantea, C. Luciliæ, C. sardensis, and different muscari. This has been much admired, and is, I think, worthy of a note. I propose trying another sedum bed, with the best of the smaller and lower-growing species of narcissus.

Auriculas and Primulas should constitute the two chief features at the R.H.S. meeting on Tuesday. As the exhibition of the southern section of the National Auricula Society will be held, and as the season has on the whole been favourable, it has the promise of being one of the best shows the society has held for some years past. The exhibition will continue open until five o'clock.

Hyacinths in Hyde and Regent's Parks are now a most beautiful sight, while their fragrance is not offensively strong, though they are cultivated in enormous numbers. It is the general opinion, with which we concur, that in no preceding year have these bulbous plants been seen to better advantage in the parks named, and in no other season have the arrangements and colour effects been so skilful and beautiful. The beds are first-rate object lessons in combinations of colour, and gardeners should avail themselves of the opportunity these displays afford of making the acquaintance of many handsome varieties not yet so well known as their merits deserve.

A Winter Garden at Hastings will probably be one of the attractions of this fine seaside town in the near future. It is proposed to erect a handsome building that will be capable of holding four thousand people; the estimated cost is between £30,000 and £40,000.

Fertilisation of the Yucca.—The fertilisation of the yucca by means of the grubs of the yucca moth (*Pronuba yuccasella*) is a remarkable example of complex instinct. As so well described by Mr. C. Lloyd Morgan, the silvery, straw-coloured moths emerge from their chrysalis cases just when the large, yellowish-white, bell-shaped flowers of the yucca open, each for a single night. From the anthers of one of these flowers the female moth collects the golden pollen, and kneads the adhesive material into a little pellet, which she holds beneath her head by means of the greatly enlarged bristly palps. Thus laden, she flies off and seeks another flower. Having found one, she pierces with the sharp lancets of her ovipositor the tissue of the pistil, lays her eggs among the ovules, and then, darting to the top of the stigma, stuffs the fertilising pollen-pellet into its funnel-shaped opening. Now, the visits of the moth are necessary to the plant. It has been experimentally proved that, in the absence of the insects, no pollen can reach the stigma to fertilise the ovules, and the fertilisation of the ovules is necessary to the larvæ, which in four or five days are hatched from the eggs. It has been ascertained that they feed exclusively on the developing ovules, and in the absence of fertilisation the ovules would not develop. Each grub consumes some twenty ovules, and there may be three or four such grubs. But the ovary contains some two hundred ovules. Of these, therefore, say, a hundred are sacrificed to the grubs of that moth through whose instrumentality alone the remaining hundred can be fertilised and come to maturity.

The Postmen's Park.—Some very absurd notions are abroad in connection with the Postmen's Park, the open space near the General Post Office. In some journals a large amount of correspondence has been published, and from these it would be inferred that there was a great danger of the tiny park soon being built upon. If the real facts of the case had been considered much ink would have been saved; it is but a small addition to the park that is contemplated, and possibly ere this appears the necessary money will have been forthcoming, and it has been made.

An American School of Forestry, the first of its kind, has recently been founded by the State of New York. The sum of ten thousand dollars has been granted by the State Legislature to cover the expenses of the first year, and authority has been granted for the purchase of forest lands in the Aidirondack region to the extent of thirty thousand acres. This new school of forestry will be connected with the Cornell University.

Cypripedium F. S. Roberts.—The beautiful cypripedium figured in our issue of April 16 (page 249) was, by an unfortunate slip of the pen, wrongly named F. S. Ames. The name given should have been F. S. Roberts, and the description throughout applies to that fine hybrid, which is one of the introductions of Messrs. Hugh Low and Co., who named it in compliment to Mr. F. S. Roberts, of Bannerfield, Selkirk, N.B.

Scale Insects are of many kinds and very numerous, and amongst the less injurious species that are liable to be mistaken for the San José scale *(Aspidiotus perniciosus)*, are the Putman scale *(Aspidiotus ancylus)*, often fatal to current trees; the apple mussel scale *(Aspidiotus conchiformis)*, common enough in England; the camellia scale *(Aspidiotus camelliæ)*; the English walnut scale *(Aspidiotus juglans-regiæ)*; and the scurfy bark-louse *(Chionaspis furfurus)*. As the result of the extremely warm weather of April, 1896, the San José scale began breeding very early in Ohio that year; the consequence was that trees but slightly infested in the spring were thoroughly coated with scale by the time when the leaves dropped in the autumn. There being four or five generations in a year, it is calculated by Professor F. M. Webster that a single female may be the progenitor, during that period, of 1,608,040,200 individuals. Paraffin oil applied with a sprayer is, says an experienced Ohio fruit grower who has sprayed one hundred apple trees, "the remedy for the San José scale." It may be recalled that it was on "Californian pears" that quantities of living San José scale were found lately in a consignment which was landed at Hamburg, and led to the prohibitive action of the German Government. California contains the centre—at least in North America—from which the pest has gradually been spreading. At the annual session which has just been held in Paris, of the Société des Agriculteurs a motion was unanimously adopted in favour of a resort to such measures as should preserve France from invasion by the San José scale. With regard to Great Britain the Board of Agriculture is making inquiry into the subject, and will probably publish a report for the information of fruit growers. In a matter of this kind promptness is of the utmost importance. The circumstance that the San José scale particularly dislikes cold and wet should rather militate against its becoming acclimatized in this country.

The Paris Sewage Farm.—A large sewage farm has been laid out at Achères for purifying the Paris sewage before allowing it to pass into the Seine. The inhabitants of Paris number 2,500,000, and the total flow of sewage is stated to average 17,660,000 cubic feet per diem. This is collected in great intercepting sewers, which convey it by gravitation down to Clichy, where it is raised 118 ft. by powerful pumps and distributed by gravitation through the farm. The pumping engines at present installed are capable of indicating 1,200 horse-power in the aggregate, but future additions will raise this to 6,000. It is stated that experience shows that 1 acre of suitable soil can take 1,580 cubic feet of sewage daily, so that an area of about 11,120 acres would be needed to deal with the whole of the discharge of the Paris sewers. A very high degree of purification is reached, the effluent proving to contain fewer bacteria per cubic centimetre than most uncontaminated streams. The land also has been greatly increased in value, being now worth five times as much as it was before being made the receptacle for the sewage. As a natural consequence, neighbouring landowners, who originally had fiercely opposed the establishment of a sewage farm in their midst, are now claiming to have the sewage supplied to their own properties. The farm at Achères is 2,471 acres in extent, and is under the control of M. Bona, a civil engineer, who in the main raises beetroot, though this crop will admit of much less sewage being passed on to the land than certain others. The main conveying the sewage from the pumping station is 43·2 in. in diameter, whilst a secondary system of pipes, ranging from 31 in. to 16 in. in diameter, serve as feeders to the irrigation trenches, into which the sewage passes through 11½ in. valves. The ground is laid out, and the irrigating trenches are so arranged that the only service needed in regulating the flow, is the opening or closing of the regulating valves just mentioned. The crop which can stand the most sewage is grass, a meadow being, it is stated, uninjured by a flow of 2,430,000 cubic feet per acre per year; lucerne can take 1,790,000 cubic feet per annum; artichokes, 593,000 cubic feet per annum; flowers, parsley, sorrel, &c., 536,000 cubic feet; leeks, cabbages, and celery, 325,000 cubic feet per annum; whilst beetroots, carrots, and beans will take only 197,000, and potatos, asparagus, and peas but 141,000 cubic feet per acre per year.

San Jose Scale.—The Dutch Government is taking prompt measures to deal with the San José scale, should the necessity arise. Dr. Ritzema Bos, the leading authority on crop pests in Holland, has been commissioned to visit the United States in order to make a personal investigation of the subject. On leaving Amsterdam he came to England so that he might discuss the matter with Miss Ormerod, and on Saturday last he sailed from Southampton. In addition to his entomological qualifications Dr. Ritzema Bos is one of the highest living authorities on the Anguillulidæ.

The Largest Nursery of the European Continent is said to be that of the Messrs. Spaeth, at Rixdorf. This nursery, according to the *National Nurseryman*, includes 700 acres, 680 of which are planted with stock, which comprises practically all the trees and shrubs that can be grown in the open air in that climate. The business was established in 1720 by Christopher Spaeth, the great-grandfather of the present proprietors. It has remained in the hands of the Spaeth family and in direct line continuously from father to son. The order has been as follows: 1720 to 1746, Christopher Spaeth; 1746 to 1782, Carl Friederich Spaeth, I.; 1782 to 1831, Carl Friederich Spaeth, II.; 1831 to 1863, Johann Carl Ludwig Spaeth; 1863 to 1898, Franz Ludwig Spaeth. By means of an elaborate system of ditches throughout the large nursery, affording unusual facilities for draining and irrigation, many kinds of nursery stock not generally grown in European nurseries are handled. The annual output of the Spaeth nurseries consists of 500,000 standard fruit trees, 300,000 dwarf fruit trees, 3,000,000 ornamental trees, 1,000,000 shrubs, and 500,000 conifers. Between 300 and 400 employés are given work in the nursery. The employés have a sick benefit association with a membership of 500, a kindergarten to which sixty children besides those of the employés and officers are admitted, and a restaurant. There is also a library connected with the institution containing many foreign publications, which are at the disposal of the young gardeners.

Aconite or Monkshood.—In dealing with the natural order Ranunculaceæ from an economic point of view, in *Knowledge*, Mr. J. R. Jackson, A.L.S., refers to the acrid and poisonous properties of the Monkshood (*Aconitum napellus*). He shows that the aconite is valued economically both for the rhizome, or rootstock, and for the leaves, both of which contain the alkaloid *aconitine*, though the rhizomes are said to be six times stronger than the leaves. The rootstock is most active in the winter and early spring, and for medical purposes should be collected at those periods. The fresh rhizome varies in size from three to six inches long, broad at one end, and tapering to a fine point. It descends perpendicularly into the ground, and gives off numerous rootlets. It has an earthly odour, and a taste which is slightly bitter at first, but which is succeeded in a few minutes by a burning sensation, and a tingling or numbness in the lips, cheeks, or tongue. The market is mostly supplied with aconite root from the wild plants, but some of the dried root is imported from Germany. Though aconitine is one of the most virulent poisons known, it is an extremely valuable medicine. Tincture of aconite is much used for outward application to allay pain in rheumatic and similar affections. The accidents that sometimes occur from mistaking aconite root for horseradish can only happen at the time when the plants are leafless, as the foliage of the two plants is very distinct; and even then the tapering and dark-coloured root of the aconite is quite different in appearance to the long, cylindrical light-coloured root of the horseradish. Several other plants belonging to the same order, natives chiefly of America and India, furnish useful medicines. The small black seeds known as fennel-flower seeds are also the produce of a ranunculaceous plant—Nigella sativa, an annual of the south of Europe, Levant, &c. The common name is derived from the fennel-like odour the seeds have when fresh. In the East they are used as a carminative medicine and for flavouring curries, as well as to keep insects from woollen cloths.

Manures for Celery.—Dr. Bernard Dyer's experiments in celery growing at Hadlow have been conducted under the disadvantage of several dry seasons, and celery is a crop that cannot well do without a plentiful supply of moisture. He has endeavoured, he states in the *Agricultural Gazette*, to grow the crop with the same dressings of manure that have been used in experiments with many other crops, viz., a "heavy" dressing of fifty loads (say twenty-five tons) per acre, a "light" dressing of twenty-five loads (say twelve and a half tons) per acre on another plot, and a similar dressing of twenty-five loads per acre on several other plots, with the addition of various quantities of chemical fertilisers. In moderately wet seasons, or on rich garden soil retentive of moisture, we should probably have grown good crops in this way, but the manure, although placed in the trenches in the usual way, has been insufficient in such dry seasons as we have had, even with the aid of chemical fertilisers, to produce heavy crops. The chemical fertilisers, viz., phosphates with and without kainit, and with nitrate of soda in quantities varying from one to four hundredweights per acre, when used in conjunction with manure, have very largely raised the crop, as compared with manure alone. In 1896 the crop grown with phosphates and four hundredweight of nitrate of soda per acre, in conjunction with twenty-five loads of farmyard manure per acre, gave a crop 10 per cent. in excess of that produced by fifty loads farmyard manure per acre. In 1895 a like dressing gave the same results as heavy manuring, but in 1897 the heavy dressing gave somewhat the best crop. In ordinary celery growing it is customary to use dressings of manure very greatly in excess of what we have used even on our heavily-manured plot. We hoped to ascertain if these heavy quantities could be replaced by the liberal use of chemical fertilisers in addition to smaller quantities of manure, but the weather has been too dry to satisfactorily test the question. We have each year grown good marketable celery, and even that is something to accomplish in very poor and newly-converted agricultural land, with what a market gardener would regard as meagre dressings of manure, and in what, under any circumstances, would at Hadlow be, owing to the weather, bad celery seasons. Although good celery, however, it has been too small to properly gauge the productive capabilities of the soil and the manure under really favourable circumstances, our best crop having averaged only twenty ounces per "head." Our experiments clearly establish the fact that a liberal use of nitrate of soda in conjunction with phosphates, when added to manure, greatly increases the weight of the crop, but, in dry weather at all events, it appears to be desirable to use more manure than we did, in addition to the chemical fertilisers, in order to enable the latter to do the full work of which they are capable.

The Beech-bark Felt-scale *(Cryptococcus fagi)* has special reference made to it in Miss Ormerod's annual report, and what she has to say with regard to the pest is specially worthy of notice, the more particularly in that it is a member of the family Coccidæ. The felt-scale itself is by no means new to the insect fauna of Great Britain, for it is not only widely distributed, but it is extremely injurious to beech trees, the bark of which becomes covered with the felt-like material secreted by myriads of the coccids. As their generic name implies, they are exceedingly small, but owing to their immense numbers they are powerful for mischief, which is effected by piercing the tissues of the tree and sucking the plant juices. A year ago, at Rangemore, Burton-on-Trent, on Lord Burton's property, this pest was reported to be "destroying all the beech trees in the woods," and there are various records of its destructive work in other parts of the country. Scale insects generally have the capacity of multiplying with great rapidity, and this particular member of the group forms no exception to the rule. Unfortunately, no very effective means are at present known for coping with the pest, though it is surmised that soft-soap washes, with a little sulphur or some kind of mineral oil incorporated with them, would be retained by the "felt," and by contact would destroy the insects and eggs beneath. "But," as the author remarks, "here, as with other forest insect attacks, it would be impossible at a paying rate to apply dressings to large areas of infested woodland; small numbers of trees, or trees which, for any particular reason, it was wished should be preserved, might in all probability be cleared from the attack, but further than that remedial measures do not seem available."

A MORNING MIXTURE.

Diluculo surgere saluberrimum est.

I FANCIED I could see the twinkle in the editorial eye as he popped on that seductive heading, "An Evening Dose." Of course I began a smile of complacency, already tasting the sweet nectar of that flattery which imitation brings. But, Phœbus! what a reawakening! I have scarcely got over the shock yet. A few more such "doses" and I shall seriously contemplate handing over this column bodily to Peter. There are certain mixtures which have to be well shaken before taken. This, however, is one of those doses which reverse the order of events, and severely shake the miserable mixer.

Let me, however, hark back a little bit. It will serve a double purpose—enable me to get a little breath, and also to acknowledge a very handsome and unexpected compliment. For the soft answer that turneth away wrath commend me to Mr. Lees. I ventured on a mild expostulation at the introduction of autumn flowers when we were all trying to forget about everything except glorious spring; and behold! the assailed one retorts with an offer to send a few young specimens of the plant objected to, in order to bring me round to a wiser view. What can I say but that I am abashed and silenced at the genial good-nature of this rare-spirited gardener, and gratefully accept his offer? The very thought of it refreshes me. It is as jam to the powder compared with that terrible evening dose. Mr. Lees may rest assured that the plants he sends will have the best of care, although they may not be handled with quite the same skill as they would have received from the giver.

Somehow or other I can never resist an opening for breaking a lance with "A. D." Not that I bear him the slightest ill-will. I know—few, perhaps, so well—that under his somewhat rugged exterior there is a kindly heart and a deep, single-hearted love of gardening. But a critic so keen and persistent is bound to raise antagonisms, even though they be friendly ones. Here is "A. D." coming to the rescue of Mr. Prinsep, and thumping me heartily. But the excellent Buxted gardener might well cry, "Save me from my friends." "A. D." thinks I have misread Mr. Prinsep. Well, all I can say is that on page 161 the latter plainly declared that he had "grown the heaviest crop of potatos ever produced in England," a line or two afterwards alluding to thirty or forty tons per acre. If the latter does not convey a definite statement of a marvellous crop, the former does, and taken in juxtaposition with each other, anyone may be excused who connects them. However, nothing is more simple than to settle the matter. Did Mr. Prinsep's crop—"the heaviest ever produced in England"—exceed thirty tons per acre? If it was not a full acre, what was the extent of ground and the quantity of produce lifted? We can easily calculate then. "Records" are the order of the day; let us get at the potato record. Mr. Beckett's testimony proves that I am not the only celebrity who is interested on the point.

Mr. Fish defends the old peach-grower valiantly. All honour to him and them. But his attempt to controvert what I still regard as an absolutely incontrovertible proof of the greater tenderness of peaches will not do at all. When you see, as I have seen, plums and peaches in the same soil, on the same stocks, growing side by side, showing absolutely different results after a hard spring frost, you may take it for granted that neither soil nor stock is at fault, but relative hardiness alone. Plums, Mr. Fish, make "fishing-rod" shoots as freely as peaches do, but they are not cut in the same way. I should not dream of accepting the inference that soil and stocks are in fault in the nursery, because that would be putting blame on the nurseryman which he does not deserve. The leading trade growers take the utmost pains to furnish their trees with firm, ripe bearing wood for their own protection. I hope I shall not give offence if I say that as far as my observation goes there are more instances of good nursery trees made gross garden ones than overgrown trade stuff toned down in private places.

Whenever there is a general movement on well-defined lines depend upon it there is some well-marked economic cause. There has for many years been a steady movement in the direction of substituting indoor for outdoor peach culture. The fact is, the cheapening of glass and timber has led to what would have been done half a century or more ago under similar economic conditions. Peach growers of those days would have gladly availed themselves of the advantages which now exist, if it had been in their power. I have before wondered at the simplicity of the plea that it is the overlooking of the fly which leads to so many troubles with outdoor peaches. We have thousands of growers who produce splendid peaches under glass, and they succeed because they pay attention to the salient points—cleanliness, careful training, prevention of exuberance, &c. Well, are we to assume that directly these successful growers get into the open air, all their skill goes off at their finger tips? Do they fail to recognize the deadly "fly," and lose all idea of ripe wood? I might first add, as something of a peach grower, that the fly is black and not green.

It is not often that I can trip up so practical a man as Mr. Wythes in a transparent fallacy, but I think I have him on the hip over those raspberries, or perhaps I ought to say over the soil. The idea that food elements are washed down to the drainage when a light soil is deeply worked, is utterly wrong; the exact reverse happens. Would Mr. Wythes try to turn Nature upset down? If so, then he has tackled a more redoubtable adversary even than Peter. What about capillary attraction? Rains that tend to take food elements down are periodical; capillarity that tends to take them up is practically incessant. I know this truth is not widely recognised, but it is a truth all the same. If I am not mistaken, I read an article bearing on this in the MAGAZINE some time ago. I read, too, the report of a lecture on Dutch bulb-growing, by one of our leading nurserymen. He spoke of hyacinths in the open air, with trusses eight inches long, grown in sand worked five feet deep, and fed with cow manure. There is a lesson in working light soil for you.

Not less sweeping is Mr. Wythes on the pruning question. "Are we," he asks, "to ruin our prospects of splendid new canes and big crops because of the time it takes to remove the old ones?" What deadly suggestion have I made that the comprehensive word "ruin" should come in? Properly-pruned raspberries are never crowded, even when they have their full complement of fruiting and new wood. Leave the pruning till autumn, and there is still no crowding, because, if judgment is exercised at the annual cutting, every shoot, old and young, has abundance of air and sunlight. This is a natural outcome of intelligently studying the habit of the plant, which is absolutely different to that of fruit trees. A grape vine really gives a better parallel. I do not suppose Mr. Wythes cuts his laterals back to the base directly he has removed the bunches any more than I do. He leaves them to ripen, so that the elaborated sap may nourish the basal buds as it recedes. The comparison is not exact, but it suffices, and it is practical.

"Suggestions"! *Ma foi*, I am all but paralysed with horror at the levity of a correspondent on page 232. I am keeping the MAGAZINE out of my henchman's way until I have got him in a cheerful mood. Then, perhaps, I can gather in the lightnings of the breaking storm, and send them along the wire.

LUX.

GARDEN RANUNCULUSES.

BOTANICALLY the garden ranunculuses are known as Ranunculus asiaticus, but through selection and crossing of the different varieties of the species they are now usually classed into three or more distinct sections, such as Persian, French, and Turban ranunculuses, and a selected forms of Persian varieties are sometimes called Scottish ranunculuses, having peculiarly striped, spotted, and variegated flowers. For all ordinary purposes, however, the three former sections will suffice. The difference between Persian (usually double Persian) and French is therefore not so very great, excepting that the latter have finer, larger, and brighter-coloured flowers, all perfectly double. The Turban varieties are of more vigorous growth, usually with larger and coarser foliage, and self-coloured, perfect, rose-shaped flowers, and are earlier than the other forms. On this account they are the best adapted for bedding, and especially for parks in or near large towns.

These garden ranunculuses, as I shall collectively call them, because, after all, there is really very little difference between the sections, are, without doubt, among the most showy and useful of plants, and those who have ever seen them in perfection will say the same. For some unknown reason they have, generally speaking, gone almost out of culture in this country, and, in fact, it is very rare indeed one sees them, and then only put in the most unsuitable soil or position, and often overgrown by shrubs or weeds. On the Continent, especially in France, some parts of Belgium, and Holland they are still in great favour, and much attention is paid to their culture, though even here they are not always seen at their best. To grow them successfully, the soil should be neither too dry nor too damp, but well drained and light, no matter what the constituents. The most favourable results are usually had when well-ripened roots have been planted in a somewhat alluvial soil mixed with leafmould and plenty of coarse sand, with a position sheltered against cold, drying winds, as well as the fierce rays of the sun, though not shady, or even partially so. To have a succession of bloom it is advisable to plant the ranunculus in three distinct sets—the first, say, in November, in a cold frame, the second in March, and the third in April or May; the last two sets, of course, in the open ground. They can be planted right into the summer, but unless well protected against sun and heat these are of very short duration, and the plants sometimes die off before the flowers develop.

As the roots of these magnificent plants are so very cheap, a hundred of them only costing a few shillings, it is best to plant them in beds like tulips or crocuses, and only in well-prepared soil, covering the beds after planting with cocoa-nut fibre; if planted during the winter, cover with straw, which should be taken away when the danger of frost has passed; then with a little protection, such as shrubs or trees afford, and sufficient moisture, a good crop of flowers is certain, and there are few plants as variable in colour and as beautiful when in perfection. There are all shades of colours, excepting, perhaps, blue; but yellow, purple, crimson, black, white, salmon, &c., are all represented, and the flowers are often deliciously scented, and consequently most useful at all seasons. For those who have never grown the ranunculus, I enumerate a few of the best varieties, although there are a great number impossible to describe or enumerate here.

DOUBLE PERSIAN RANUNCULUS.—Bouton d'Or, double [illegible]; Citrone, yellow; Jaune Supréme, yellow; Queen of the Netherlands, black; Brilliant Orange, orange; Queen Victoria, violet; Mont Blanc, white.

DOUBLE FRENCH RANUNCULUS.—Duc de Brabant, light orange; Emperor Frederick, orange; Pio Nono, black-brown; The Shah, pale yellow; L'Etincelante, crimson; Salvator Rosa, scarlet; Couleur Café, dark brown; Mathilde Christine, white.

DOUBLE TURBAN RANUNCULUS.—Viridiflora, green, the petals red tipped; Grandiflora, crimson, yellow striped; Herculus, white; [illegible], scarlet; Seraphic d'Alger, yellow; Turban Carmine, carmine coloured; Sans Pareil, scarlet.

As with some anemones, the little claw-like tubers of these ranunculuses retain their vitality, when kept dry, for two years, and sometimes longer, provided they were well ripened.

G. REUTHE.

THE GHENT QUINQUENNIAL HORTICULTURAL EXHIBITION.

The great exhibition, which has attracted immense numbers of horticulturists from all parts of Europe to Ghent during the past week, is in every way a splendid success, and worthy of the city which has long been recognised as one of the most important centres of horticultural activity on the continent of Europe. It is the fourteenth of the quinquennial exhibitions instituted by the Société Royale d'Agriculture et de Botanique de Gand, and there is a remarkable consensus of opinion among both citizens and visitors that it is unquestionably the best. In the seven hundred classes provided in the admirably arranged schedule all kinds of ornamental plants that can be shown to advantage at this season of the year are represented, and the immense number of collections testify in no doubtful manner to the high-class skill of the Belgian and other cultivators who have taken part in the exhibition. Palms and cycads of magnificent proportions abound; plants remarkable for the beauty of their foliage, other than cycads and palms, are contributed in immense numbers and splendid condition; orchids are shown in numbers equal to those staged on previous occasions; and hard-wooded plants, grown for the beauty of their flowers, are plentiful, and serve to remind the British visitors of the splendidly-developed Cape and New Holland plants, which for so long a time constituted the most important and attractive features of the exhibitions held in London and other of the great centres of the United Kingdom. The large number of collections could hardly have failed to give rise to a feeling of regret that no longer can we see at home in any considerable numbers specimens of hard-wooded plants equal to those so plentiful at Ghent. The great feature of the gathering is unquestionably that formed by the azaleas, of which considerably over a thousand plants, ranging from eighteen inches to eight feet in diameter, are shown, producing a wealth of colour, of which no one who has not seen the display can have an adequate idea. A portion of the azaleas are shown in the accompanying illustration of the exhibition house, which will be useful as indicating the character of the plants and the taste with which they were grouped with a view to general effect.

RARE PALMS EXHIBITED BY THE SOCIETE HORTICOLE GANTOISE, GHENT QUINQUENNIAL.

As on several occasions, the exhibition is held in the magnificent winter garden and the grounds of the Casino, which is conveniently situated on the north-west side of the city. The winter garden is a large building of iron and glass, and, as will be seen from the illustration given herewith, is extremely elegant in design. The ground floor of this spacious building was laid out by M. Ed. Pynaert, who is one of the ruling spirits of the horticultural institutions at Ghent, to form a series of mounds, slopes, and banks, intersected with broad walks, with a miniature lake, lawn, and rockwork in the centre. The illustration of the winter garden will indicate the general arrangement of the structure, although a portion only of the building is shown. In the winter garden are arranged the greater portion of the plants remarkable for nobility of aspect or the beauty of their foliage and colour is given by the resplendent hues of the leafage of the crotons and dracænas, and by the brilliant scarlet spathes of Anthurium Scherzerianum, of which there are numerous collections of magnificent specimens. The anthuriums are, indeed, shown in such large numbers and splendid condition as to constitute a striking feature. Two groups of orchids, and both remarkably good, also have a place in the winter garden, as also has the interesting collection of plants shown by M. Lucien Linden in memory of the late M. J. Linden, all the plants represented having been introduced by that distinguished collector and horticulturist, who, as our readers have been informed, died during the past few months. The collections of orchids other than groups are arranged in the salle of the Casino, and the corridors are devoted to bulbous and new plants, botanical diagrams and specimens, plans of gardens and estates, and many other objects of interest.

The accommodation afforded by the winter garden for tender plants was again supplemented by an immense annexe, which for convenience may be described as the exhibition hall. This has been erected from a design similar to that of five years ago, and may be described as a span-roof building of wood, glass, and canvas, many hundreds of feet in length and width, and some thirty or forty feet in height. A portion of the roof is of glass, and to subdue the light and enhance the appearance of the building thin canvas in alternate bands of pale yellow and mauve is suspended beneath the roof, as so well shown in the illustration. The sides and pillars are painted a light green, and the general scheme of colouring may be described as exceedingly pleasing. Two series of oblong beds are arranged along the centre, flanked by broad raised banks on either end, and at the exteme end is a large circular bed, considerably raised, surrounded by irregular slopes and with a bank round the sides. On the large circular raised bed the magnificent specimens of azaleas shown by Comte de Kerchove and M. Ghellinck de Walle are arranged to form a trophy group, and although one may not agree with the formal style of training adopted, it was impossible to avoid being impressed by the extreme splendour of the display. These specimens are shown in the distance in the illustration of the exhibition hall. The oblong beds, of which a portion are shown, are devoted to the large collections of medium-sized azaleas. Greenhouse plants are arranged round the sides of the building with exceptionally fine Van Geer kentias, seaforthias, and other palms thriving in the cool house.

The general plan of the exhibition hall is similar to that adopted on the occasion of the quinquennial gathering held five years since, and it is difficult to conceive one that would be more suitable for the purpose. The building, in consequence of the much larger space required for the accommodation of greenhouse plants, has been made one-third larger, and it is connected with the winter garden, which is a manifest advantage. The grand saloon through which access is obtained to the winter garden is reached by two flights of steps, and between these is a huge mirror, which reflects the majority of the groups arranged in the building, and adds immensely to the effect. From the balcony connecting the two flights a magnificent view of the whole arrangements is obtained, and this balcony was more or less crowded throughout each of the days we were at the exhibition.

The social functions constitute an important part of the Ghent quinquennials, and this gathering is in no way an exception to the rule. If anything, the hospitality was more lavish than on previous occasions, and the best traditions of the city in this respect are being fully maintained. On the morning of the 15th inst. the members of the jury began to assemble at the place of exhibition at nine o'clock, and on their meeting in the grand saloon shortly before ten, the Comte de Kerchove, president of the society, offered them a hearty welcome to Ghent. The roll was then called, and the Britishers who answered to their names were: Drs. Bayley Balfour and Maxwell T. Masters, and Messrs. William Bull, George Gordon, E. Hill, J. Hudson, W. Iceton, H. J. Jones, R. W. Ker, J. Laing, D. P. Laird, Hugh Low, F. W. Moore, J. O'Brien, Owen Thomas, W. Protheroe, Thomas Rochford, F. Sander, A. Turner, J. H. Veitch, William Watson, J. Weathers, H. Williams, and Brian Wynne. As the names were called the members advanced to the table, signed their names in a large book especially provided for these gatherings. This formality having been disposed of, the President expressed the satisfaction that was felt by the executive of the Ghent society in having the assistance of the delegates of the principal societies of Amsterdam, Berlin, Dresden, Geneva, London, Paris, Vienna, and St. Petersburg in bringing to a successful conclusion the quinquennial exhibition. Comte de Kerchove then addressed the jury, and directed attention to the remarkable development which the Ghent exhibitions had undergone since they were instituted. The first exhibition was held under the auspices of the society on February 7 and the three following days, 1809, and a room of comparatively small dimensions was sufficient for the accommodation of the plants shown; but on this occasion six thousand seven hundred and fifty-two square metres were required for the display of the collections in competition. The exhibition afforded ample evidence of the great development which the taste for horticulture had undergone, and of the assistance the society had received from the State, the province, the city, and its members in carrying out the project. Comte de Kerchove also testified to the support received from the King of the Belgians, whom he described as the foremost amateur in the kingdom. The society had, he believed, done much useful work in aiding in the development of a taste for plants, which were now so largely employed in beautifying the home. The art of horticulture had, he said, greatly extended in and near the city of Ghent of late years, and in proof of the correctness of his views upon that point, he said that whereas there were one hundred and eight nurseries in 1889, there are now two hundred and thirty-nine establishments. The Count then spoke of the large number of beautiful plants which had been introduced from their native habitats, or produced by the skill of the hybridist, and of the valuable work accomplished by previous occupants of the presidental chair. He also paid a warm tribute to the memory of the late M. Jean Linden, and directed attention to the interesting collection of plants introduced by that great collector and explorer which had been arranged in the winter garden. Speaking of the labours of the jury, Comte de Kerchove said the exhibitors were eagerly awaiting the decision of the jury as to the relative merits of the production, for awards made by the eminent horticulturists he had the honour of addressing were the greatest honours that could be obtained.

At the close of the address the members were arranged in thirty-nine sections, with M. Leon de Bruyn, the Belgian Minister of Agriculture, as honorary president, and M. O. Viger, president of the National Horticultural Society of France, as president general. The jury then proceeded to make the awards, and this was in many instances a very difficult task. At the close of their labours the members were entertained at lunch, Comte de Kerchove occupying the chair. This function occupied the greater part of the afternoon, owing to the number and length of the speeches. The speeches, if of greater length than those to which we are accustomed in the United Kingdom, were for the most part remarkably good. In the course of the proceedings, Dr. Masters presented in felicitous terms the Veitch Memorial medals that had been granted by the trustees to M. Ed. André and Comte de Kerchove, both of whom acknowledged in suitable terms the honour that had been done them. This presentation was followed by M. Viger investing M. E. Pynaert with the insignia of a knight of the order of Mérite Agricole, a proceeding which invoked much enthusiasm, as indeed did the presentation of the Veitchian medals. In the evening the members of the jury were invited to a reception by the Burgermaster and a concert at the Hotel de Ville. The reception was a very pleasant function, but the concert was not well suited to the occasion, and but few members remained for any length of time.

On Saturday morning, the 16th, the exhibition was formally opened by the King of the Belgians, under the most favourable climatic conditions. His Majesty, accompanied by the Queen of the Belgians, Princess Clementine, and suite, reached the Casino a few minutes after eight o'clock After a few of the members of the executive had been introduced to the King, the royal party made a leisurely inspection of the exhibition, leaving shortly before noon. In passing through the grand saloon a pause was made by the royal party for the purpose of enabling his Majesty to receive the members of the jury. Saturday was practically a free day, the only public function being the Raout in the evening offered to the visitors by the Chambre Syndicale de Horticulture. This gathering took place in the saloons of the Union Society, and was a pleasant affair. The 17th inst. was a busy day, for the jury was invited by the king to a garden party in the winter garden at Laeken, and this was an exceedingly brilliant affair, some fifteen hundred being present. This was followed by a grand banquet to the jury in the saloons of the Grand Theatre, Ghent, at which the Comte de Kerchove presided. The principal speakers were the same as at the luncheon on the previous Friday, and, as on that occasion, the speeches were, in most cases, long; but the whole of the proceedings were so extremely pleasant that the prolixity of some of the speakers in no way troubled the guests, and, after all, so important and successful a gathering justified the many matters of interest being talked about, and it must be said that the banquet was not less satisfactory than were the other arrangements.

Indian Azaleas.

Azaleas were exhibited in immense numbers and in magnificent condition, and arranged in huge beds and bold groups; they produced a wealth of colour and constituted a glorious feature. The Indian azaleas, for which the Ghent exhibitions have long been famous, were of exceptional excellence, and produced so brilliant a display as to prove highly attractive to the many Britishers present. The specimens were mostly in the form of standards with rather flat heads, and although rather too formal to satisfy æsthetic tastes they were so attractive as to disarm criticism with regard to the style of training that finds favour with the Belgian cultivators. In the class for twelve specimens the Comte de Kerchove, Ghent, was awarded the gold medal offered as the first prize with large, neatly-trained, and densely-flowered specimens. The varieties staged included Louise Margottin, a beautiful variety, the flowers white flaked deep rose; Roi Leopold, scarlet, very fine; Princess Louise, semi-double, salmon pink, the specimen seven feet in diameter, and so freely flowered that hardly a leaf was visible; Le Vengeur, glowing rose, the edges elegantly frilled; Louise Vervaen, pure white, the flowers very large; A. Borsig, double white, one of the best of its section; Comte de Chambord, delicate pink with white margins, flowers large, fine shape; Concinna, rose purple, very fine.

The most important collection of azaleas from a spectacular point of view was the collection of thirty specimens from M. Ghellinck de Walle, Ghent. The specimens ranged from six to eight feet in diameter, were literally solid with bloom, and these thirty giants arranged to form a trophy at the north end of the exhibition house produced a startling effect. Taking the number of plants, the size of the individual specimens, and the superb development of the flowers into consideration the collection may be described as the finest that has yet been presented at a public exhibition, and the award of the object of art offered as the first prize to M. Ghellinck de Walle was well deserved. The most remarkable of these magnificent examples were Souvenir de Lyon, Maenhout, Comte de Chambord, Bijou de Paris, Theodor Korner, Baron de Vriere, Roi Leopold, Hoorbrenki, Duchesse Adelaide Nassau, Marie Vervaen, Madame Ambroise Verschaffelt, and Harry Veitch. M. Ad. d'Haene, who also was awarded an object of art, had a collection of large finely flowered specimens.

One of the most interesting of the classes provided for Indian azaleas was that for sixty plants in pots of limited size. There was a spirited competition, and in the several collections all the best of the new and old varieties were represented. The premier award was a work of art of the value of two hundred francs, presented by MM. de Smet; and gold medals were offered as the second and third prizes. The several collections were so evenly matched in point of merit as to have given rise to considerable difficulty in determining their relative merits. In the result the premier award was made in favour of Société Anonyme Horticole (Louis Van Houtte, père), who had superbly-flowered examples, with heads ranging from eighteen inches to two feet in diameter, and remarkable for their extreme freshness. Among the many fine varieties represented in the collection the following were made note of as being of exceptional excellence: M. J. de Fontanier, glowing rose, semi-double; Souvenir of Duke of Albany, pure white, with an occasional flake of rose; Louise Cuvilier, white, flaked vermilion, semi-double; Pauline Mardier, soft rose, pleasing, double; Madame Ad. d'Haene, bright pink, carmine blotch; Baronne de Vriere, pure white, with an occasional rose stripe, margin elegantly frilled; Oberst von Kutzinci, rich scarlet, semi-double, very fine; Perle de Ledeberg, white, freely flaked with vermilion, semi-double, exquisitely beautiful; Gloriana, fl. pl., white, suffused green in early stages; Baron N. de Rothschild, rich purple, semi-double, effective; Comte Chambord, delicate pink, with carmine blotch; President Pfaff, scarlet; Madame J. Vervaen, soft pink, with rose blotch; Aristides Effendi Azarian, deep pink, with white margin, singularly beautiful; President Oswald de Kerchove, salmon-pink, semi-double, beautiful; Madame W. Van Houtte, pink, paler margin; Princess Mathilde, white, with vermilion stripes and flakes; Comte Ernest Turati, rich crimson-purple; Germania, glowing rose-red; M. Leopold Botelberg, Melle-by-Gand, was a close second, his plants being a size smaller than were those in the first-prize collection, but they were superbly bloomed, and the flowers were in the highest state of development. The varieties of exceptional excellence represented in the collection included Vervæneana soft salmon-pink with carmine blotch and white margin, semi-double; Anna Kleine, pure white semi-double; Comte Charles de Kerchove, pink with carmine blotch; Madame Vandercruyssen, glowing rose, superb form, very effective; Roi de Holland, vermilion; Niobe, double white; Baronne de Puynode, flesh freely flaked like a carnation, exquisitely beautiful. The small gold medal in this class was awarded to M. A. Van Acker, Loochristy with an excellent collection, and the silver-gilt medal was awarded Messrs. F. Sander and Co., St. Albans, with a collection that in the opinion of some experts deserved a higher position in the competition. The plants were remarkable for their uniform size and for the superb development of the individual blooms. It included several exceedingly beautiful varieties not represented in the other collections, notably Konigen der Weissen, pure white, immense size, and grand form; Frau Herman Seidel, pure white, semi-double; Arlequin, rose-pink striped, and flaked purple, distinct and showy; Violacea multiflora, purple, rich and effective in contrast with the red and salmon shades; Miss Bertha Frobel, green-white, distinct flower; [illegible], brilliant scarlet; Rosea picta, flesh white, freely flaked with rose, a charming and attractive variety; Baron Von Horn, rich rose flower, finely frilled.

Two excellent collections were staged in the great class for one hundred varieties of azaleas without restriction as to the size of pots. The class was of interest from the fact of its affording the large cultivators an opportunity of exhibiting all the most noteworthy varieties in one collection. M. Ad. d'Haene, Gendbrugge, occupied the post of honour with medium sized and superbly flowered examples, in which the following varieties were conspicuous by reason of their high merit: Noble Belgique, salmon and pink; Hermione, brilliant rose; Gloria Belgica, white, prettily striped like a scarlet-flaked carnation; Charles Lieber, white, striped with rose purple and of superb form; Camille Vervaen, brilliant rose red; Imperatrice des Indes, delicate pink with dark border; Edmond Vervaen, rich red carmine; Roi de Holland, an old but excellent scarlet variety; Memoire L. Van Houtte, fulgent rose, large and of superb form; Lina Boreim, pink, small, double, but very desirable for the supply of cut flowers; Princess Mathilde; Madame Leon Chabot, pink with carmine blotch, exquisitely beautiful. The second award was made in favour of Société Anonyme (L. Van Houtte, père), Ghent, who had large densely flowered specimens. The most noteworthy varieties were: Cocarde Orange, brilliant orange scarlet, semi-double; Victor Cuvilier, red magenta; Mons. J. de Fontanier, semi-double, rosy red; Noblissima, double white, flowers very large, grand form; Stephenson Clark, rich rose carmine, semi-double, very fine; Souvenir d'Arthur Veitch, deep scarlet; Madame de Grève, pale pink, white margin, carmine markings; Dr. Moore, rose magenta, very effective; Duchesse Ferdinand Munez, white, scarlet stripes; P. N[illegible], white, vermilion flakes, large very effective; Madame J. E. Planchon, white, freely striped pink, pleasing and effective; Theodore Reimers, rich purple, semi-double, very effective; Mdlle. M. Planchon, pure white, elegantly fringed, Professor Walters, deep vermilion blotch on upper segments and pale pink margin, one of the finest of this pleasing shade of colour; Pluto, glowing scarlet, the finest of its colour; J. T. D. Llewellyn, flesh pink, deeper in centre, double, superb form; Eugene Mazel, orange scarlet, with violet blotch, effective; Hermosa, soft rose pink, double; Archduke Ernest, orange red, large.

The groups of twenty azaleas were of great excellence, and the large number of collections in the two classes for this number of plants contributed their full share to the display produced by the Indian azaleas. The varieties were chiefly the same as the larger classes to which reference is made above. The Comte de Kerchove was the recipient of the work of art offered in the amateurs' class for twenty plants, and M. Ad. d'Haene was awarded an object of art in the trade class for twenty, and MM. Vervaen frères were awarded a gold medal. The premier award for a specimen azalea with double flowers, was obtained by M. J. F. Vervaen-Vaveart, Ledeberg, Gand, with a grafted plant trained in a pyramid with the several varieties to form distinct bands of colour. At the base was a broad band of rose-coloured flowers; following this was a ring of pure flowers, next rose-coloured flowers deeper in hue than those at the base, and at the apex was a cone of pure white flowers. Specimens of this character are of interest as indicating the ingenuity of the cultivator, but they have little to recommend them for the purpose of embellishing the greenhouse and conservatory.

Mollis and Ghent Azaleas.

Varieties of Azalea mollis are strongly represented, both in point of numbers and the development of the plants; and the masses of yellow, primrose, orange and buff flowers produce a bright and pleasing effect. The finest collection is that of thirty plants from M. A. de Smet, Ghent, who was awarded the gold medal. The whole of the plants were grown in standard form, and carry large finely-developed heads of bloom. In a second class for thirty plants of Azalea mollis, M Pynaert van Geert was awarded the gold medal for [illegible] developed bushes. M. B. Spae obtained premier honours for twenty [illegible] MM. Koster et fils, Boskrop, were first for the same number obtained from the intercrossing of mollis and sinensis, with well-grown examples. The plants shown were mostly unnamed, and, judging from the immense number exhibited it would appear that the Belgian raisers have not made much progress [illegible] development. Ghent azaleas were represented by several collections consisting of well-bloomed examples, but the varieties shown do not call for any special remark. The finest collection of thirty plants was contributed by Société Anonyme Horticole, to which was awarded the large gold medal.

New Azaleas.

New azaleas were not very numerously shown, and a few only of those exhibited were of special value, being in the majority of cases too much like those already in cultivation. Betsy de Brau, from MM. Koster et fils, is a beautiful mollis variety with the flowers of a pale orange colour suffused scarlet. Mdlle. E. Eckhaute, contributed by M. Eckhaute, is a striking Indian variety, the flowers semi-double with rose pink with broad white margins and red brown spots at the base. M. Eckhaute exhibited an unnamed Indian variety, the flowers large with broad petal and of a rich rose salmon ; one of the best of the novelties.

Orchids.

Notwithstanding the large number of classes devoted to orchids the display of these was rather disappointing. The groups by M. Vincke-Dujardin, M. Peeters, and Mr. Thompson redeemed the exhibition from mediocrity, as in all these the plants represented good culture.

A most attractive group of orchids was shown by M. G. Vincke Dujardin, Bruges, and it was good enough to capture the gold medal offered by the King. It contained a glorious assortment of odontoglossums, crispum, Andersoni, and luteo-purpureum forms. Miltonia Bleuana nobilior carried seven fine blooms of exceeding beauty. Eulophiella Elizabethæ, with about three dozen flowers and buds on one spike, proved a great attraction, as did Cypripedium Rothschildeanum ; good examples of Ada aurantiaca, resplendent with spikes of orange-coloured flowers. Oncidiums abounded, especially O. tigrinum, O. Harrisonianum, O. crispum, and O. sarcodes. Cymbidium Lowianum was in force, while Cattleya Lawrenceanum superba, with three flowers, made a fine centre piece. Cymbidium eburneo-Lowianum and Phaius Cooksoni were among the rarest and most beautiful of hybrid orchids, and these with other species and varieties already mentioned were associated with a variety of masdevallias, lycastes, and dendrobiums.

A GROUP OF PLANTS ILLUSTRATING THE LATE MONS. JEAN LINDEN'S DISCOVERIES.

An exhibit of orchids from Mons. A. A. Peeters, Saint Gilles, Brussels, was beautifully set up, the flowering plants being set amid light forms of maidenhair ferns. The cattleyas were not large, neither indeed were any of the specimens, but the varieties were in all cases good. Cattleya Mossiæ Reineckiana showed up well, and had for companions C. Schröderæ, C. Bowringiana, C. Lawrenceana, the beautiful and rare C. Parthenia, with five grand flowers ; C. Parthenia gratissima, with rose-tinted segments and some golden shading in the throat ; and C. maxima. The new Phaius Norman and its varieties aurea and rosea were a feature of the exhibit, as were half a dozen examples of Zygopetalum Pierrenoudi, a hybrid recently described in these columns. Other very choice orchids in a choice collection were Phaius Cooksoni, Miltonia Bleuana nobilior, Sophronitis Veitchi, Lælio-cattleya Hippolyta, Lælia Latona, Eulophiella Elizabethæ, the pure white Cattleya intermedia var. Parthenia, Cypripedium selligerum, and Masdevallia Veitchi grandiflora. There were one hundred plants in all, and the group was awarded the object of art offered by M. le Comte de Germiny of Gouvelle, France. In M. Smet Duvivier's first prize collection of thirty orchids there was a Lycaste Skinneri alba, with seven flowers ; Cattleya Schilleriana, C. Mendelli rosea, Dendrobium thyrsiflorum, Odontoglossum cariniferum, with a long branching spike ; Oncidium lameligerum, and a fine specimen of Cymbidium eburneum.

The Williams Memorial medal was offered on this occasion for the best fifteen orchids, and it fell to M. Metdepenningen for a moderately-good collection arranged with palms. Cymbidium Lowianum, Cattleya amethystoglossa, Oncidium sarcodes, Odontoglossum Edwardi, O. Andersonianum, O. crispum, Trichopilia suavis, Cypripedium Lawrenceanum, and C. Chamberlainanum were leading specimens. A curious and interesting class was that for the largest number of species grouped together, and here M. Van Imschoot secured the gold medal ; comparatively uncommon orchids here staged were Ansellia nilotica, Eria floribunda, Dendrobium tetragonum, D. Kingianum, Angræcum Leonis, Epidendrum Cooperianum, and Lycaste lasioglossa. For three orchids representing different genera, M. de Smet Duvivier secured the only prize with Cymbidium Lowianum, Odontoglossum luteo-purpureum, and Oncidium sarcodes.

Only one competitor entered for the gold medal for thirty odontoglossums, and had there been others, we think our compatriot, Mr. Stevens, gardener to W. Thompson, Esq., Walton Grange, Stone, Staffs, would have been difficult to displace. Mr. Stevens' collection not only represented fine varieties, but excellent cultivation ; indeed, there were not better-grown odontoglossums in the whole show. Among forms of O. crispum those of especial beauty and merit were O. c. roseum leucoglossum, a fine white-lipped variety, with rosy sepals and petals ; O. c. Annie, shaded with rose and blotched with crimson, the margins of the segments waved and fringed ; O. c. Thompsoniæ, with two spikes of large, full, white flowers, with one spot on one or two of the segments—twenty-six flowers altogether. O. luteo-purpureum amplissimum, with eighteen flowers ; O. Coradenei expansum, fourteen flowers ; O. Wilckeanum nobilior, with twenty-three flowers ; O. hystrix, with three fine spikes ; O. sceptrum leopardinum, with four spikes ; and O. Roezli alba, with ten spikes, were among the most notable examples on view, though mention must be made of O. sceptrum Stevensi and O. Humeanum splendens. According to the jury, the best odontoglossum, single specimen, was O. Madame Metdepenningen, a yellow-ground form of good shape, with rich brown blotches ; it had but six flowers. Tastes differ, of course, and at home we should probably have placed Mr. Thompson's O. Halli, furnished with nine spikes, first, and here placed second.

The three new hybrid orchids that gained for M. Van Imschoot a gilt medal were Cattleya Alberta (C. Loddegisi and C. superba), we should have thought it simply a Lælio-cattleya elegans form ; Epidendrum Endresio-Wallisi, and Masdevallia Pourbaixi. M. Metdepenningen led the way for fifteen odontoglossums. In his group there was a good O. luteo-purpureum, named coronarium, the brown colour being almost crimson ; O. Ruckeri and O. guttatum also deserve mention. In a group of orchids shown by M. F. Pauwels, Antwerp, we noticed a flowering specimen of Coryanthes macrantha. The best specimen oncidium in the show was O. sarcodes, sent by M. de Langhe-Vervaene ; this is a beautiful oncid, but does not look well when the spikes are rigorously staked and tied. M. Maron, Brunoy, secured the silver-gilt medal for the best hybrid obtained between two genera ; his specimen was Lælio-cattleya Henry Greenwood, a hybrid between C. Hardyana and a form of Lælia elegans. It has very soft rose sepals and petals, the latter being broad and waved. The big lip has a broad golden throat, with an apex and marginal rim of rich purple ; the lip is very handsome and of great size. The same exhibitor contributed the best lælia—a flowering specimen of L. Digbyana. M. Maron showed a lot of cattleya and lælia hybrids, chiefly C. Louis Chalon, a cross between C Trianæ and C. Lawrenceana. Among some orchids shown by M. Henri Vanderstraeten, Bruges, was a good Cymbidium Lowianum, with heavily-coloured lip, and a good example of Cypripedium Exul.

Twenty-five cypripediums is but a moderate number to exhibit now that there are so many species, hybrids, and varieties ; for such a number M. Pynaert van Geert, Gand, gained a first prize, his rarest examples being C. bellatulum album, with one flower ; C. Exul, with ten blooms ; C. macropterum, and C. Mastersianum, carrying fifteen flowers. In a similar class, but for amateurs, M. J. Moens was to the fore, showing C. Niobe, C. selligerum majus, and C. Kienastianum, in good condition ; all the plants were rather small.

An extremely pretty form of Odontoglossum crispum named King Leopold was shown by Messrs. Sander and Co., ; the spottings of red are freely scattered over a palest rose ground. This firm also had a group of Lycaste Skinneri alba with their new plants. A case of anæctochi from M. A. Dalliere, Ghent, drew much attention, as it contained good specimens of A. Dawsoni, A. Sanderianum, A. petola, A. intermedia, &c.

New Plants.

One of the most extensive and interesting of exhibits was that staged by Messrs. F. Sander and Co., St. Albans, England, and Bruges. About thirty yards of tabling in one of the special side corridors was occupied by the display, and it certainly emphasised the energy and spirit that has hitherto been one of the great features of the St. Albans establishment. A quite large number of new plants were shown; indeed, it was practically a new plant exhibit, though some few of the species staged have now become fairly well known in leading horticultural establishments, notably Dracæna Godseffiana and the older D. Sanderiana. The latter was represented by a monster pyramidal specimen, with the leading central growths about eight feet high; it was a mass of growth, and covered with light and handsomely variegated foliage. D. Godseffiana occupied a big tub, and was a splendid mass. The new D. Broomfieldi from Thursday Island occupied a prominent position, and was admired for its stateliness; it has somewhat stiff foliage, the leaves being about eighteen inches long and three broad at their widest; green, margined with white, and streaked with palest green and white. Among palms there was a big example of Geonoma Pynaeertiana, a Malaysian plant with broad fronds, bifid at the apex, and set on very short stems; Calamus Laucheana, an elegant palm with curiously interrupted pinnæ on its fronds, three or four of these being set close together, and then a similar space left bare; the gaps are left opposite each other; Kentia Sanderiana is a graceful little geonoma-like palm with square-ended pinnæ; Kentia Warteliana will probably turn out not to be a kentia some day, it is, however, a most distinct palm with rising stem, rough and whitish; the broadly pinnate fronds are short, very thick, grey beneath, and curiously stipulate; Calamus Alberti is particularly elegant, so also is the very pale green Calamus Caroli with closely-set pinnæ; and Licuala Jeanenceyi, a native of Australasia, is akin to L. horrida, but not so well armed, its stiff, shining fronds seem to point to its value for decorative use. Panax Mastersiana is a strong-growing araliad from the Solomon Islands; for large stoves it would be useful, but it seems scarcely handsome enough for general cultivation, notwithstanding its long drooping foliage. Leea Roehrsiana is a bold species with deep metallic green foliage; it is a giant L. amabilis without its bright colouring. Aralia Balfouriana, from New Caledonia, will scarcely replace A. Guilfoylei, though distinct from it. In Pandanus Sanderi, from Timor, we have, however, a very fine pandanad that cannot fail to run P. Veitchi close for popularity; the creamy-green groundwork is lightly striated with deep green and white, and thus the plant is much more variegated than P. Veitchi, and there is a yellowish tone throughout; it is a handsome plant, and whether a distinct species or not, it is distinct enough from a horticultural point of view. A very distinct and useful plant, Acalypha Godseffiana, formed a margin to the whole group; it has green, shining leaves, with creamy white margins, these marginal bands including the serrations; it branches freely, and can thus be easily kept in good form. A prominent item in the St. Albans display was a case of the pretty Anæctochilus Leopoldi, a strong-growing species, with leaves five by six inches, deep velvety green, with veinings and pencillings of dull golden yellow; this case was received by the Messrs. Sander on March 4, after the plants had undergone a journey of four months from the Philippine Islands—they travelled amazingly well for anæctochili. Lastly, though by no means least, and certainly not finishing all the new plants—we have to mention Acalypha Sanderi, from New Guinea. This has very bold green leafage, deep green in the blade, pale green in the petiole; more remarkable than the bold leafage and stately habit are the inflorescences, one produced from the axil of each leaf, like a long crimson velvet tassel, nearly an inch thick, and from one to two feet in length. This species will certainly be grown as freely for its flowers as A. Macafeeana is for its handsome foliage; it was the most conspicuous new plant in the Sanderian group, and created much interest.

Anthuriums.

M. Arthur de Smet contributed a splendid lot of anthuriums, staging twenty large specimens of A. Scherzerianum and its varietal forms; the majority but highly cultivated forms, though A. S. atrosanguineum was very distinct by reason of its broad deep red spathes. Some freely flowered amaryllis set among the tubs of anthuriums added not a little to the general effect. A large specimen of Anthurium Scherzerianum grandiflorum was shown by M. Arthur de Smet; it was in a big tub and measured about five feet across, and carried some five dozen or so of rich scarlet spathes. This fine example only secured a second prize. A first-class silver medal was awarded the Comtesse de Kerchove for her big Anthurium Hookeri, as the best example of an anthurium showing exceptional culture, the leaves were five or more feet long and over two feet broad, and there were thirteen of them on the plant.

M. Arthur de Smet took the lead for twenty five anthuriums in flower, securing the work of art with large specimens of A. Scherzerianium, A. Souvenir d'Antoine Chantin with crimson spathes, A. Rothschildianum var. Secretaire Fierens and A. Scherzerianium var. excelsior, closely akin to A. S. Wardi. Anthuriums in great variety were well shown by the Société Anonyme, Ghent, and these secured the large gold medal offered as second prize in the class for twenty five specimens: A. atrosanguineum, A. Scherzerianum album, A. Perfection, and A. Souvenir de la Exposition in the way of A. Rothschildeanum were among the most attractive examples. A second-class gilt medal was awarded M. Arthur de Smet for six varieties of Anthurium Andreanum, and his set included a white spathed hybrid form, unnamed; a deep scarlet form; A. A. salmoneum; and A. A. sanguineum, the latter very attractive. M. Vervaene-Vervaert gained a gold medal for twenty examples of Anthurium Scherzerianum, and the second prize for a score of plants representing this species and its forms was won. M. Arthur de Smet gained the second class gold medal; A. S. salmoneum, A. Rothschildeanum Helvetia, white with big scarlet blotches, and A. S. Souvenir de A. Chantin with deep crimson spathes, were notably distinct forms in this collection.

Hardy and Tender Rhododendrons.

Rhododendrons were contributed in considerable numbers, and arranged in bold banks round the side of the exhibition hall produced a rich effect. The object of art offered as the first prize for forty specimens of hardy varieties, was awarded to M. Ed. Pynaert Van Geert, who contributed splendidly-flowered and tastefully arranged specimens. The varieties were chiefly of English origin, and included Lady Clermont, Mrs. John Penn, Charm, Joseph Whitworth, Notobilis, Barclayanum, Mrs. John Clutton, one of the best of the white varieties; Blandyanum, a fine rose-coloured form introduced to cultivation many years since; Kate Waterer, a pleasing rose-coloured variety; Sir Robert Peel, bright red; Cynthia, a superb variety, producing huge trusses of bright rose-pink flowers. Especially good was the collection of twenty-five specimens from M B. Fortie, Ghent, who was awarded, and deservedly so, the large gold medal. The specimens were of medium size and remarkable for the splendid development of the flower trusses. Especially deserving of mention were William Austin, a superb crimson form; Cynthia, Madame Masson, Madame Cavalho, J. M. Brooks, Neige et Cerise, an appropriate name for a charming variety—the flowers are produced in noble trusses, and white with bright cerise margin; Madame V. Charon, very fine, the flower brilliant crimson; Comtesse Salvi, an exquisite form, the flowers delicate lavender tinted pink; Souvenir de John Broughton, a superb variety, the flowers borne in noble trusses and of a brilliant rose pink, one of the finest of the hardy rhododendrons for flowering under glass, and Prince Camille de Rohan, flesh-pink with dark markings. M. L. Spae-Vandermeulen, Ghent, and M. Bernard Spae also contributed excellent collections to the rhododendron classes. Rhododendrons requiring the protection of a glass structure for their successful cultivation were not numerously shown, but the collections exhibited were highly meritorious. The finest collection of Japanese and Himalayan species and their hybrids was that for which Mr. Joseph Baumann, Ghent, was awarded the gold medal; it comprised large finely-flowed specimens, of which the most noteworthy were Aucklandi, a beautiful species, the flowers flesh white; Fragrantissimum, one of the finest of the white Himalayan rhododendrons; Dalhousianum, a distinct species with yellow-white flowers, which should prove useful to the hybridiser; Edgworthi, a beautiful white and fragrant form; Roseum odoratum, a handsome rose-coloured variety; Magniflorum, a superb white form in the way of Fragrantissimum but with larger and more finely-formed flowers; and Dalhousianum Victoriænum, a handsome form remarkable for the superb development of the flowers.

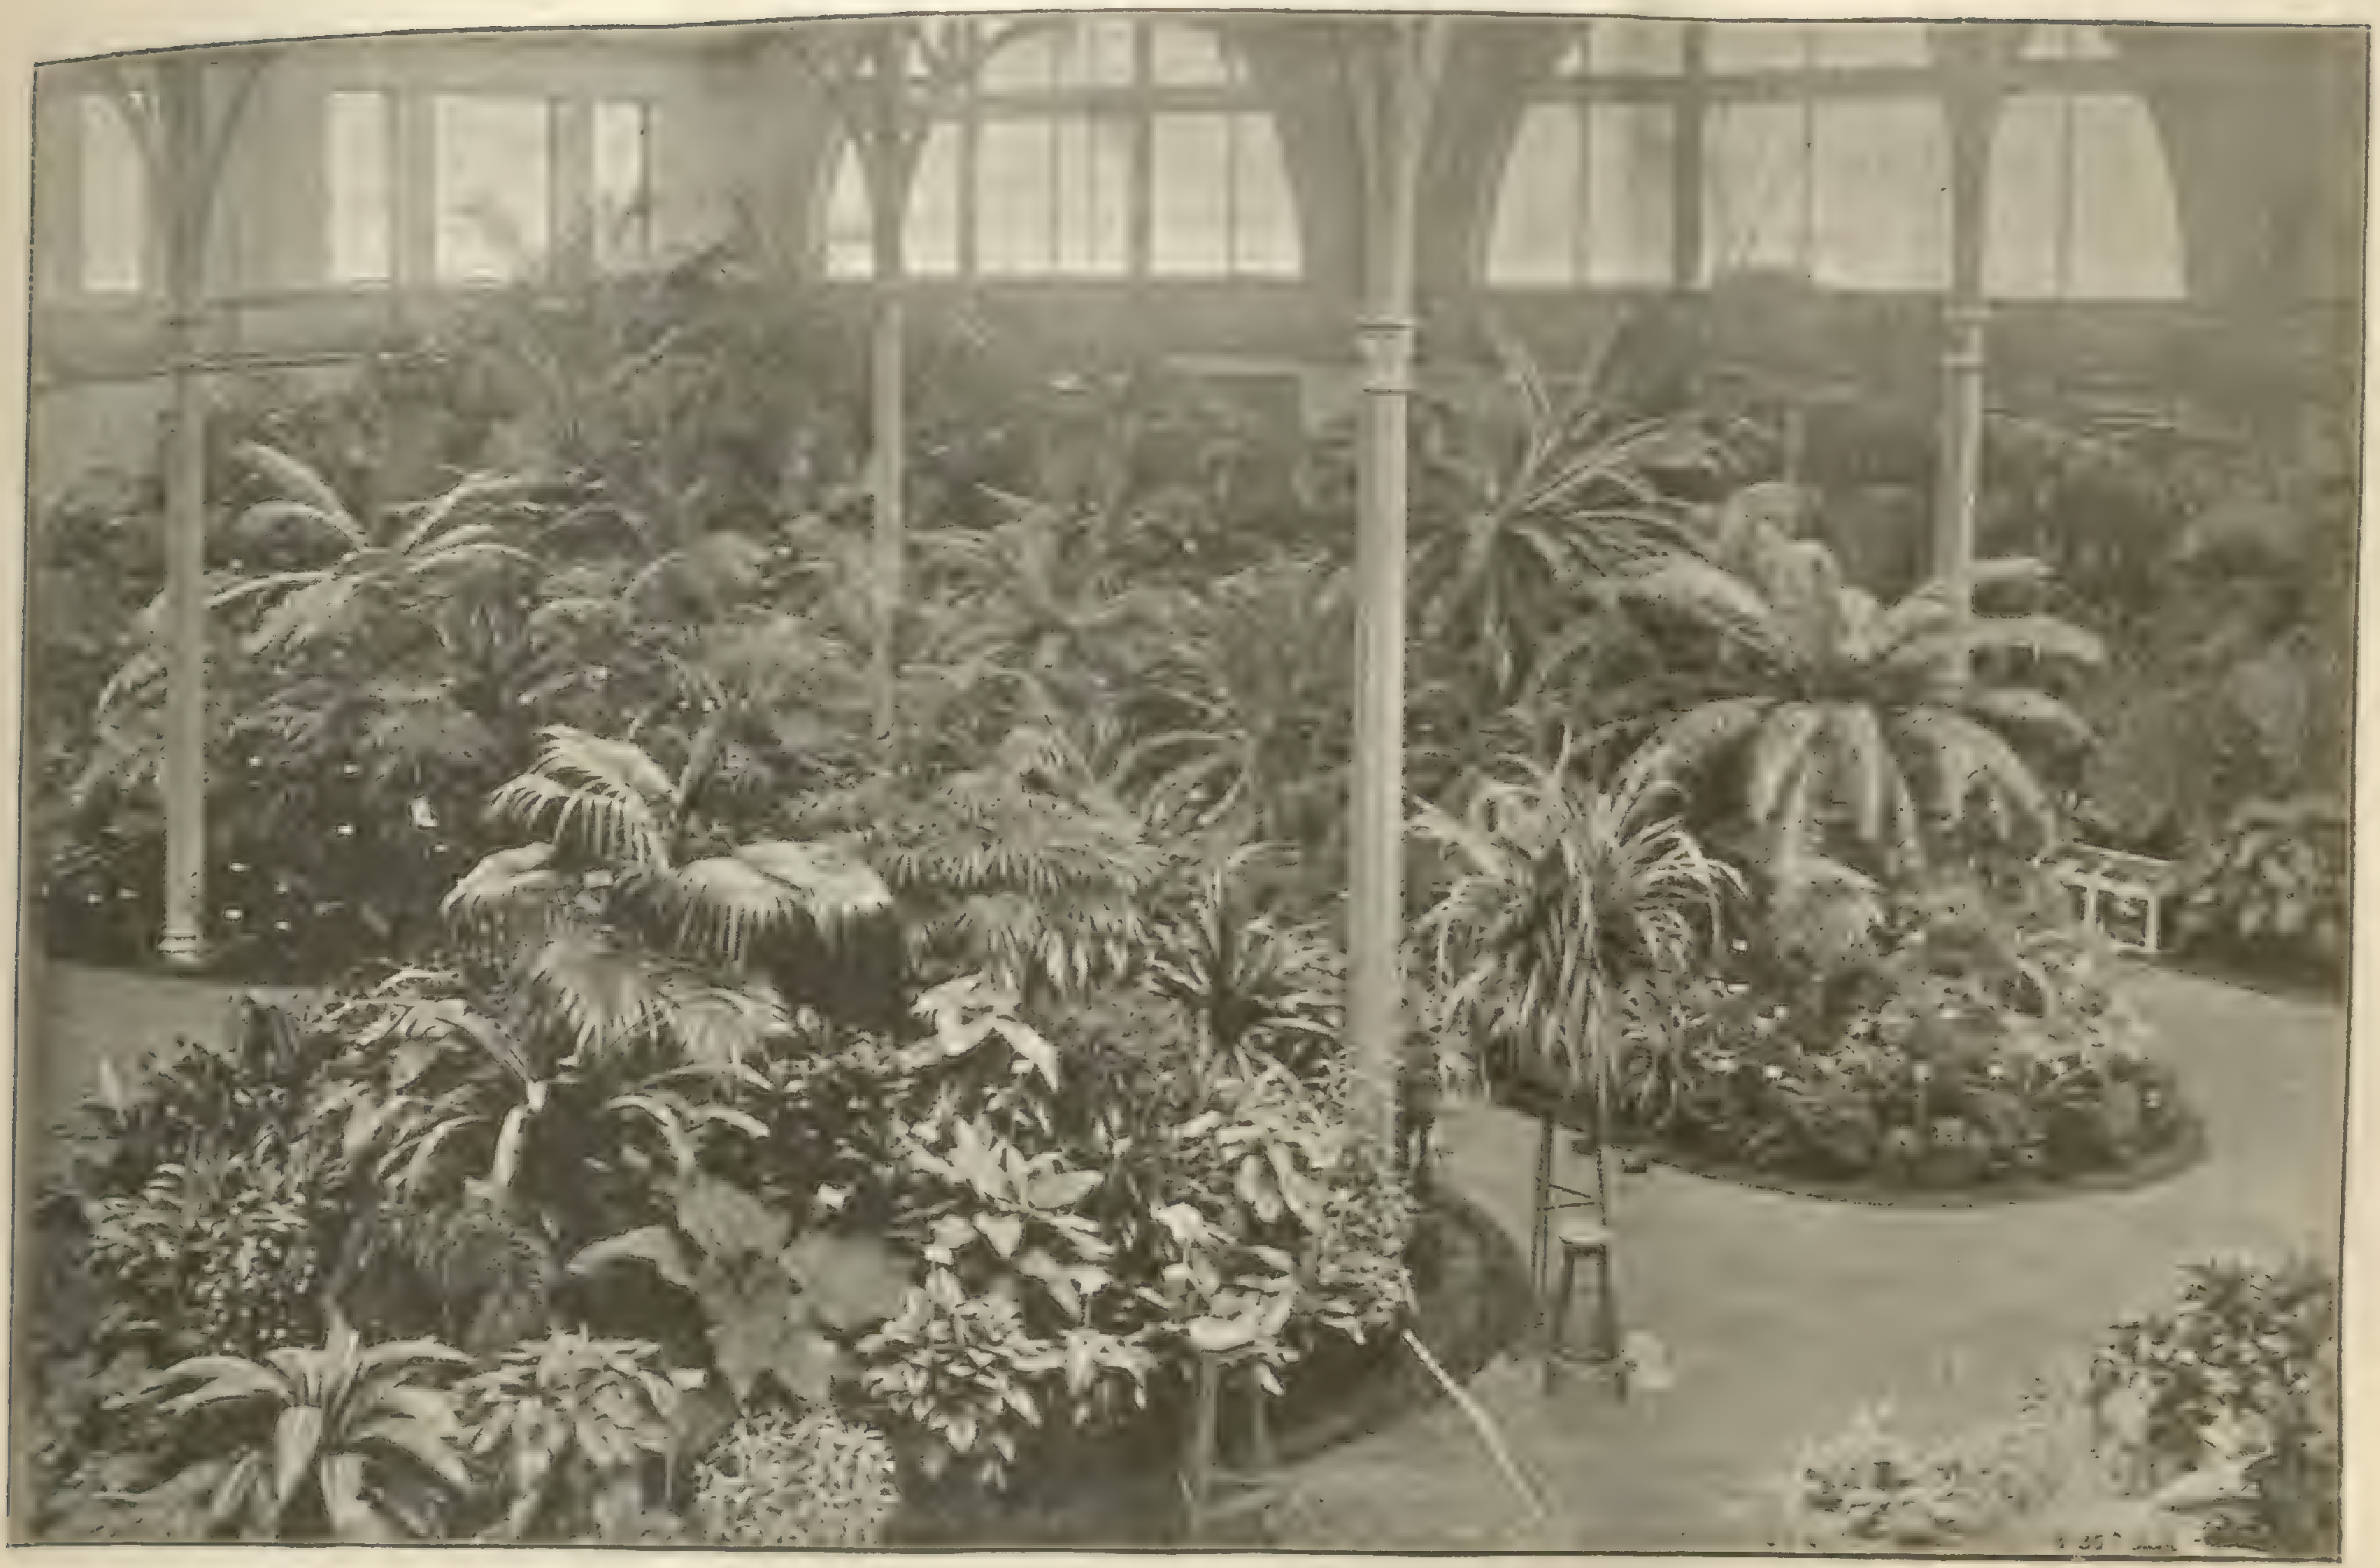
Stove Plants.

Seldom have we seen finer stove plants than were contributed in quantity at this show. Here, however, the majority of the specimens (though recognised as miscellaneous) were what we at home regard as stove plants as their names will show. In almost every case cleanliness and general high cultivation was evidence that M. Rigouts clearly won his place as the leading exhibitor at any rate, in the eyes of Britishers.

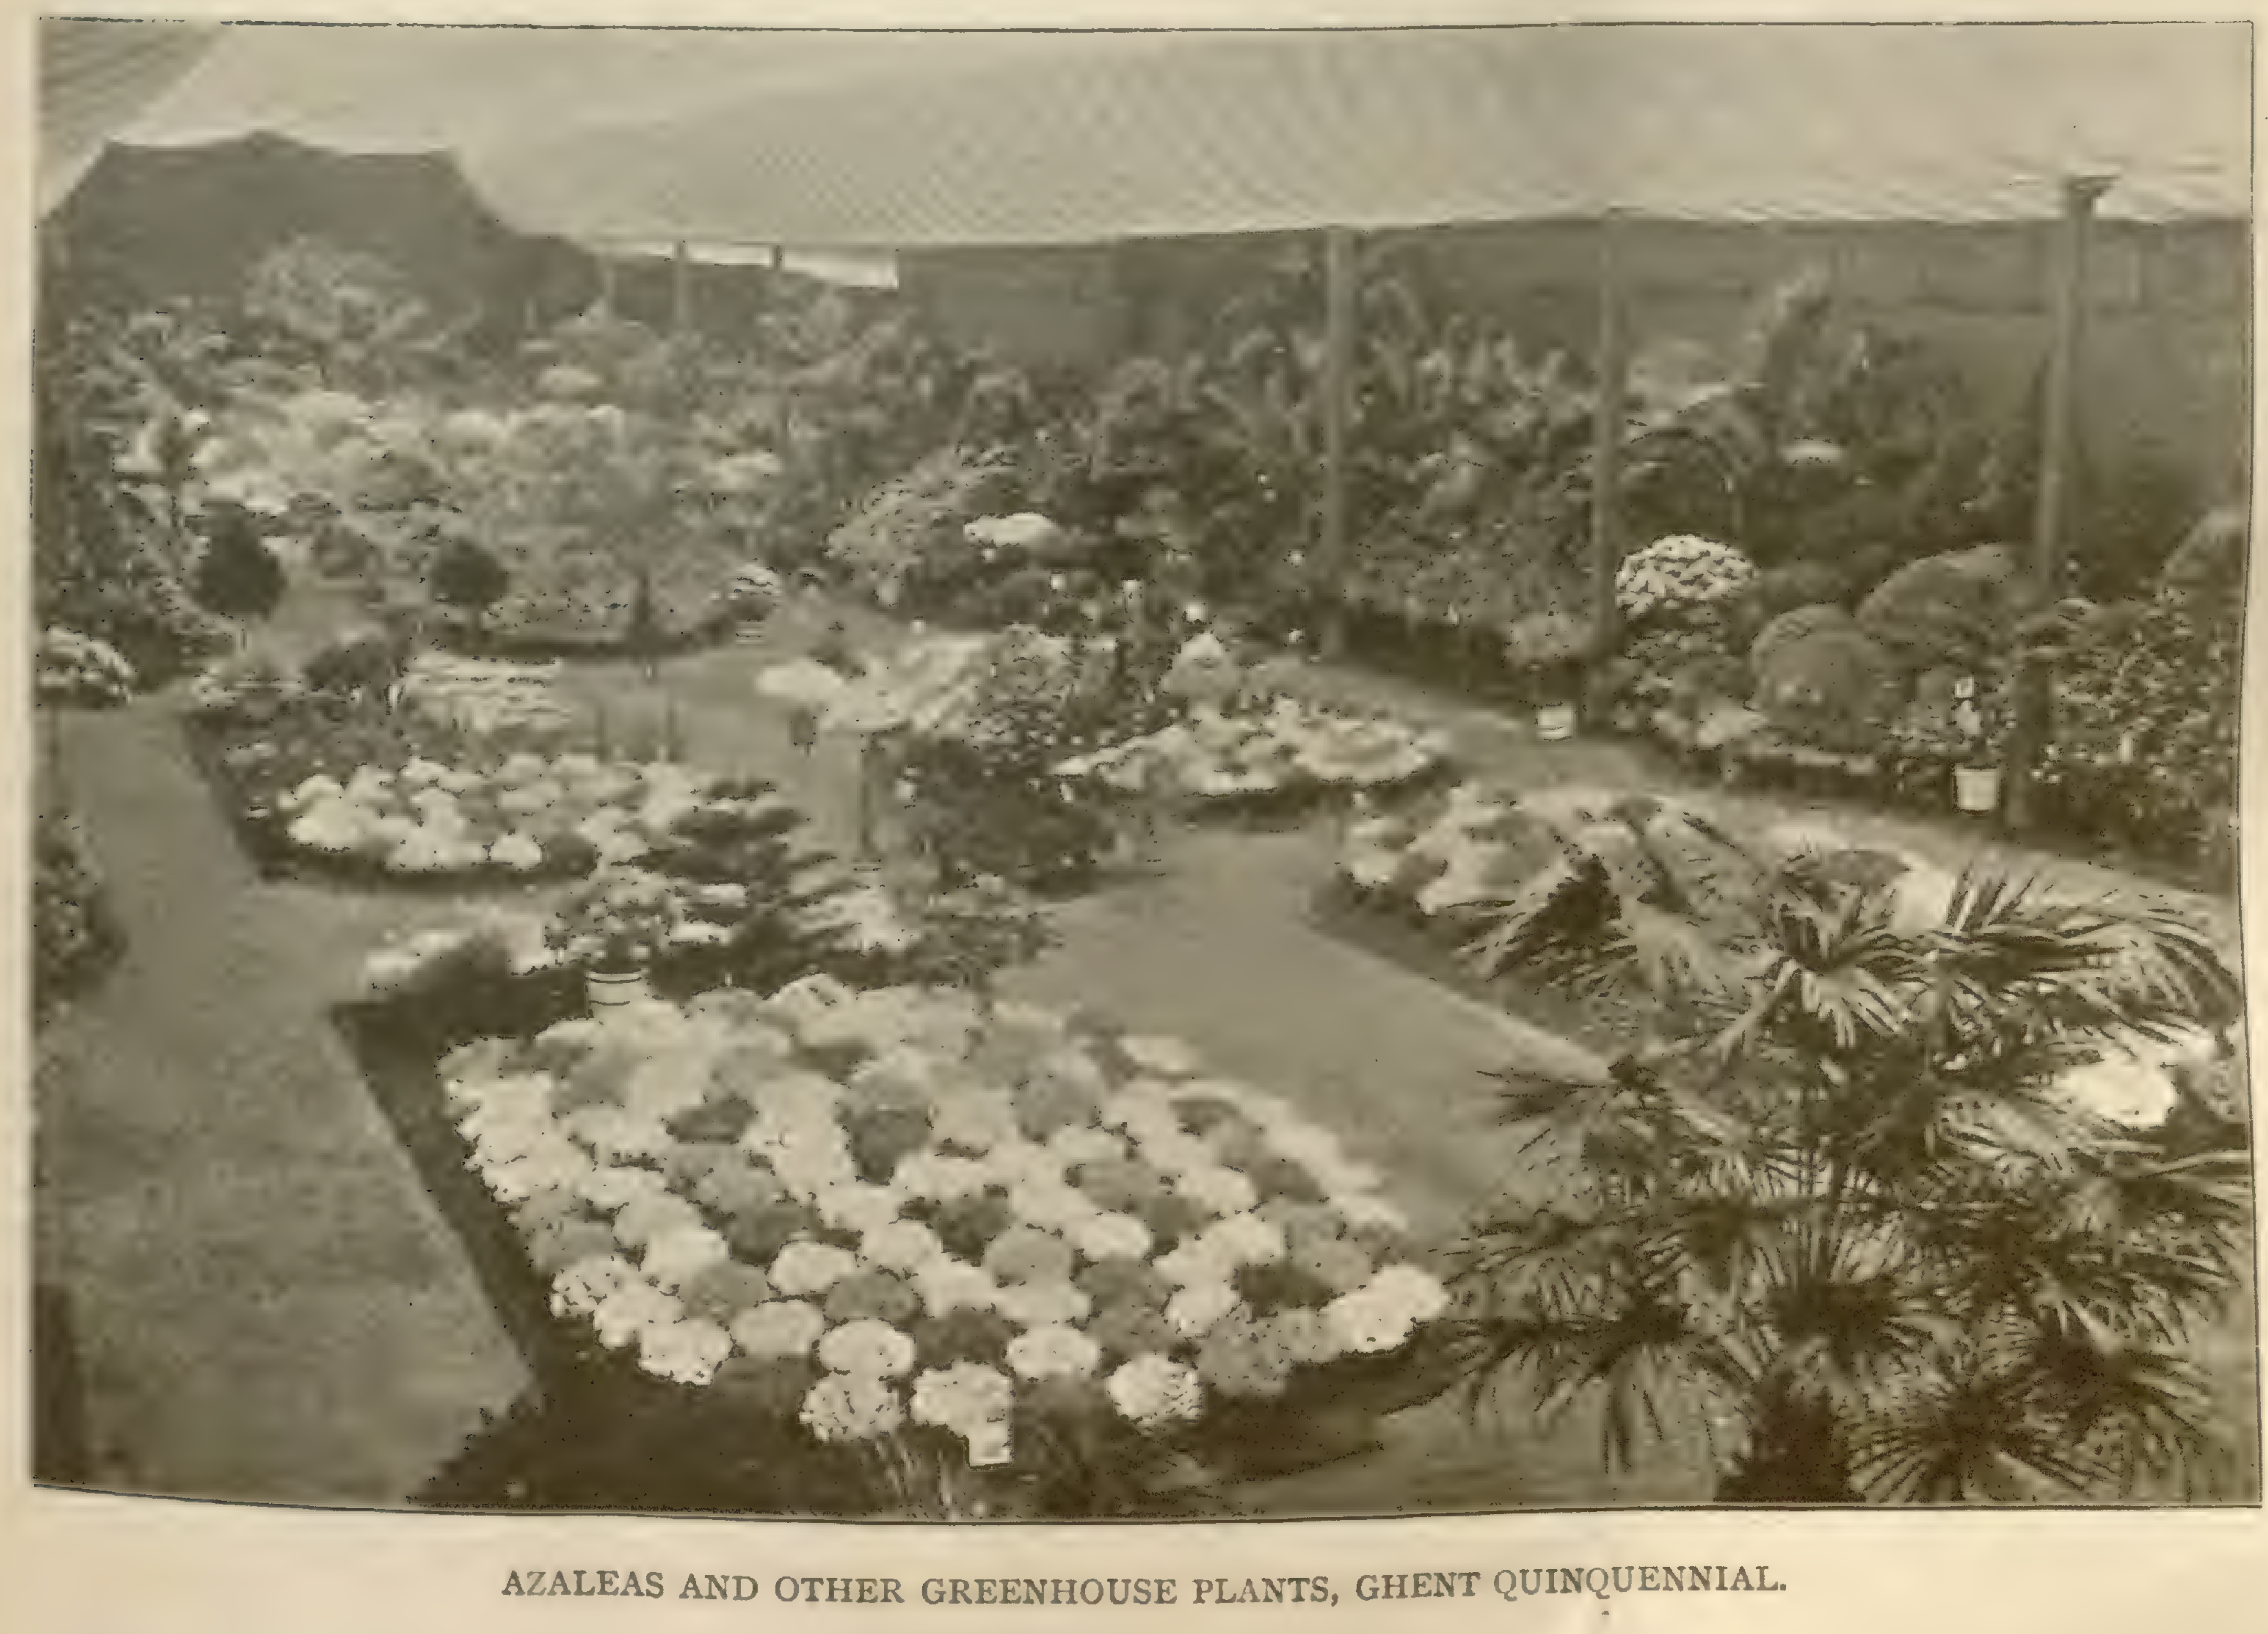
A huge bank of large specimen plants placed in tasteful arrangement before the double staircase of the winter garden of the Casino was exceptionally fine, and though some of the specimens were obviously made up, yet the majority were cultivated as shown, and exhibited a wonderful degree of cultural excellence. Such exhibits are not seen at home in these days. This display was from La Société Anonyme Horticole Gantoise, Ghent, and worthily won the Œuvre d'art, valued at 200 francs, offered as first prize for forty specimens, flowering or foliage, and in memory of M. Louis Van Houtte, pére. At the back, near the balustrading of the staircase, were fine examples of Kentia Belmoreana, Pritchardia grandis, Pandanus Veitchi, Cycas revolutum, Anthurium Veitchi, with very long foliage; Alpinia vittata, a fine clump of variegated foliage. Lower down were Dracæna Godseffiana, D. Sanderiana, Phyllotænium Lindeni, a fine plant; Alocasia gigantea, Phœnix Roebelini, exceptionally gracefully and well furnished; Eucharis amazonica, Spathiphyllum picturatum, Pavetta borbonica, Dieffenbachia Fournieri, Aralia sonchifolia, Leea amabilis, Oncidium sarcodes, and Adiantum Farleyense. The third prize fell to the firm trading as M. Louis van Houtte, pére, and the collection shown by them was staged alongside that already noticed. Big plants of Kentia Belmoreana, Alpinia vittata, Philodendron Sellowi, Cycas revoluta, Erica Cavendishi, Anthurium Veitchi, Coccoloba pubescens, and Zamia varicosa, formed a first-rate background for smaller examples of Nephtylis picturata, Dracæna Doncetti, Croton Warreni, Pimelia spectabilis, Schismatoglottis Robelini, Phœnix Robelini, Nepenthes mixta, and Dieffenbachia imperialis nobilis. The second prize, to the value of 200 francs, was awarded to M. Albert Rigouts, Meirelbeke-lez-Gand, but we are of opinion that some judges would have awarded this the chief honours of its class; it was a grand collection, and staged along the extreme end of the big hall. Towering over the centre was a large and well-grown Encephalartos, and grouped around this were noble specimens of Croton Queen Victoria, Cocos Weddelliana, Pandanus Veitchi, Alpinia vittata, Dicksonia antarctica, Dieffenbachia imperialis nobilis (with eighteen of its big spotted leaves), Philodendron Gossianum, the curious Coccolaba pubescens, and Clerondendron Balfouri. Lower down we noted a highly-coloured and handsome plant of Helicoma illustris, Pandanus Baptisti, the unspined species from the Solomon Islands; Dracæna Godseffiana, Alocasia argyrea, Polypodium difforme macrophylla, a new plant from Borneo, and a very fine fern as here shown; Vriesea Moensiana, Phœnix Roebelini, most graceful of date palms; Dracæna Sanderiana, Phyllotænium Lindeni magnificum, deserving its varietal name by reason of its robustness and more than usual complement of colour in the leafage. Orchids were represented by Cymbidium Lowianum, Odontoglossum luteo-purpureum, Oncidium ampliatum majus, and Anæctochilus petola, a pan two feet in diameter filled with the pretty green and gold foliage of this pretty little orchid.

There were a considerable number of groups of twenty-five stove plants with coloured foliage, and the premier collection was arranged by H. Millet-Richard, Ledeberg; it was a fine set, the plants being all beautifully clean and splendidly cultivated, though not of enormous size; Cyanophyllum magnificum, Alocasia metallica, Spathiphyllum pictum, Hibiscus Cooperi, Maranta regalis, Dieffenbachia Fourneri (grandly coloured) Dracæna Goldiana, D. Godseffiana, Curculigo recurvata variegata, and Anthurium Warocqueanum were a few notable plants in a splendid set. Another success of M. Rigouts was the winning of second prize—a gold medal to the value of 150 francs—for twenty-five stove foliage plants remarkable for striped, marbled, or spotted leafage; Aglaonema picta, Heliconia illustris, Dieffenbachia Jenmani, and Nephtytis picturata attracted our attention to this group. A handsome set of stove plants arranged in a sloping bank near the rustic bridge and water was contributed by the Société Horticole Gantoise, and merited a small gold medal; due regard to the colour of foliage had been evinced in the arrangement. The most notable plants were Heliconia illustris, highly-coloured Spathiphyllum picturatum, Dieffenbachia magnifica (its [illegible] spots showing well against the green ground colour), Dracæna Godseffiana, Leea amabilis, Alocasia Lindeni, and Croton Czar Alexander (a large-leaved form with gold veins on a green and brownish ground). Fifteen plants of Pandanus Veitchi from M. K. J. Kuyk, Mont St. Amand, made an effective group near the orchids; but a set of larger plants arranged by MM. de Verdonck, [illegible], made quite a little pandanad forest. One of the largest specimen pandanus in the was a towering example of P. Desmetianum, a bold green-leaved form shown by M. Pynaert van Geert, and securing for him a silver medal.

The chief award for fifteen ornamental foliaged plants was gained by M. [illegible] de Cock, Ghent, with some large spreading palms of popular kinds, as [illegible] and Ciboteum Sheidei, Philodendron Corsiensis, Cycas revoluta, &c. [illegible] Société Horticole Gantoise again scored for twenty miscellaneous plants, [illegible] similar kinds to those otherwise referred to. In the nurserymen's [illegible] twenty miscellaneous plants, M. van den Abeele gained second place [illegible] interesting collection that included handsome specimens of Adiantum Farleyense, Cymbidium Lowi, Maranta Sanderiana, Cyanophyllum magnificum, Vriesea [illegible]lata, a small Ataccia cristata, Anthurium crystallinum, and Ag[illegible]belini. In the same class plants staged by M. A. Rigouts gained a [illegible] medal; notable plants here were Aglaeonema costa, beautifully [illegible] admirably grown; Dracæna Godseffiana, in full flower; Curculigo [illegible] medio-picta, a form with several creamy-white regular bands down the [illegible] the leaf; Anthurium crystallinum, Philodendron Melinoni, Alocasia Lindeni, and [illegible] Oncidium Marshallianum. For six plants with handsome foliage, and [illegible]



VIEW IN THE WINTER GARDEN, GHENT QUINQUENNIAL.



AZALEAS AND OTHER GREENHOUSE PLANTS, GHENT QUINQUENNIAL.

ing as many different genera, M. A. Rigouts was placed first with Peperoma argyrea, an old plant now not often seen; Dracæna Sanderiana, Dieffenbachia Jenmanni, Maranta Veitchi, Pandanus amaryclidifolius, and Croton Oerstedti (labelled Aureo-punctatissima). Mons Gustave Botelberge, Ghent, showed four large tubs of Atrelizia Reginæ, carrying in the aggregate twenty spikes of their curious yellow and purple-blue flowers; such large examples are scarcely ever seen in this country outside our leading botanic gardens.

M. Rigouts practically swept the board when competing in classes for stove plants, and he secured a gold medal for twelve specimens with ornamental foliage with the same kinds of plants as shown and enumerated elsewhere. Abutilon Sellowianum in the third prize set of twelve stove plants was remarkable for its thick but soft foliage, quite yellow, finely speckled with green and brown, and veined palest green; this was shown by M. Millet-Richard, Ledeberg. M. Rigouts secured the silver-gilt medal for half-a-dozen specimen stove foliage plants, Croton Andreanum, Alocasia pucciana, and Croton Baron J. de Rothschild being conspicuous. The first prize group of twenty miscellaneous plants, amateurs, was from M. Bedinghaus; big ferns and dieffenbachias were shown in addition to pretty examples of Acacia cordata, Ruellia Mackoyana, with deep rosy flowers; Vriesia Lubbersi, with three spikes, Eriostemon linifolium, &c.

Camellias.

Camellias were not contributed in large numbers, but those shown were of great merit and remarkable for profusion of flowering, having regard to the comparatively late period. In the great class for thirty, M. L. Eckhaute, St. Denis, Westrem, was awarded the first prize, consisting of an object of art, for spendidly developed specimens, chiefly trained in pyramidal form, and freely flowered. The varieties were mostly those well known in the United Kingdom, but we noticed a few beautiful varieties that are comparatively unknown in this country. One of the finest of these is Madame Cochet, which has large and superbly formed flowers, of a delicate flesh colour, occasionally striped and flaked with brilliant carmine. Camellias: Société Anonyme Horticole were awarded a gold medal for an excellent collection. The finest of the collections of camellias was that of fifteen plants shown by M. E. de Cock.

Dracænas and Crotons.

The Société Horticole Gantoise secured the large gold medal offered for twenty-five handsome foliaged dracænas; all the specimens were well grown, though the colours were scarcely so brilliant as one would expect a month or two later. D. Goldieana, D. Gladstonei, D. Wilsoni, D. Barteti, and D. amabilis were represented by handsome specimens with robust foliage right down to the pots. Near the water basin a group of dracænas did not seem so much out of keeping as at first one would imagine them; these were a second prize lot, and gained a gold medal of the second class; D. Lindeni, D. Baptiste, D. Norwoodiense, D. imperialis, D. amabilis, D. Smetiana, D. speciosa, and D. Alphonse de Cock were the most attractive examples.

The twelve crotons that secured for La Société Horticole Gantoise the first prize in their class were beautifully coloured and moderately large bushy specimens, clean and most attractive, the collection forming a fine patch of colour near some dracænas and aroids. The varieties shown were Madame Bause, Sunshine, Madame Linden (very broad gold and green foliage), Mons. Bause, Madame Ruffant, Morti, Countess, Madame Bruant, Madame Leon Duval, Georges Lebucer, Amiral Cuverville, and Albert Truffant.

Cycads.

The finest lot of fifteen cycads came from M. de Ghellinck de Walle, and it speaks volumes for plant culture in Belgium that such a collection should come from one establishment: Encephalartos Altensteeini, E. horrida, Zamia Perowskiana, Z. Lehmanni, Dioon edule, Cycas circinalis, Z. Ghellincki (a feathery form with tomentose foliage), Z. masura, Z. vernicosa, Z. Katzeriana, Z. Maclura, Cycas revoluta (with a trunk five and a half feet high), Z. Hildebrandi, and Cycas scamensis, a very handsome cycas, well furnished.

Palms.

For fifteen rare palms the Société Horticole Gantoise was awarded the gold medal as first prize for Licuala Dr. Oxley, Calamus subangularis, Daemonorops javanensis, Geononia acaulis, one of the species with short stems and undivided fronds; Chamærops hystrix, Livistonia Hoogendorpi, Ceratolobus concolor, a light green form; Brahea havanensis, Trachycarpus Khasyanus, Penanga Kuhli, a fairly good plant of the common coco-nut palm Cocos nucifera; Oncospermum Van Houtteanum, Licuala grandis, and the Oil Palm, Elais guineensis. The chief attraction in the fifteen classes for palms was the class for twenty-five specimens, the first prize being a work of art offered by M. le Comte de Kerchove de Denterghen, president of the society. This coveted award fell to the Société Horticole Gantoise for a collection of handsome, large and clean specimens that fully occupied one big corner of the largest hall. Chief among these palms were Thrinax chuco, Maximiliana regia, Verschaffelia splendida, Cocos insigne, Livistonia chinensis, Kentia australis, a Phœnicophorum, Areca lutescens, a big clump; Wallichia oblongifolia, Chamædorea elegans, Kentia Lindeni, a pretty plant of Caryota urens; the spiny Astrocaryum mexicana, with two flower spikes; Thrinax elegans, and a huge Rhapis flabelliformis.

In the nurserymen's class for fifteen large palms the first prize was unanimously awarded to M. Em. de Cock for examples that could only find space in huge houses or where the summer climate would allow of their being put out of doors Thrinax argentea, Ceroxylon niveum, Kentia Forsteriana, Phœnix senegalensis, Rhapis flabelliformis, Arenga saccharifera, Livistonia altissima, Geonoma imperialis, and the graceful Thrinax grandiflora were conspicuous examples. The gold medal offered as a second prize for fifteen palms (nurserymen) was won by M. Albert Rigouts with very large specimens, the set including Kentia australis, Rhapis flabelliformis, Sabal Blackburnianum, Areca Baueri, Seaforthia elegans, over twenty feet high, and a fine specimen of Phœnix senegalensis.

Among the palms shown by M. Ad. de Clercq-van-Ghyseghem, Ledeberg, was a finely variegated Latania borbonica, quite a large specimen.

Ferns and Asparagus.

A handsome group of ferns, forming a splendid bank by the rustic bridge and pond in the winter garden, constituted a collection of thirty tree and other ferns, and was beautifully in keeping with the surroundings of grass and water. This lot came from the Comtesse de Kerchove's collection, and included among the larger examples big specimens of Cibotium Barometz, C. princeps, Cyathea medullaris, Marratia Willincki, and Angiopteris evecta. Smaller specimens were of Adiantum sancta Katherinæ, A. assimile, Polypodium Billardieri, Goniophlebium glaucophyllum, Davallia epiphylla, Oleandra nodosa, and Asplenium bulbiferum. An interesting group of twelve ornamental asparagus, shown by MM. Duriez frères, contained fair specimens of A. deflexus, A. tenuissimus, A. medius, A. plumosus nanus, A. comorensis, A. plumosus cristatus, A. Broussonetti, A. retrofractus aborescens, A. Sprengeri, and A. virgatus, the latter a decidedly handsome plant, though not so valuable for cutting as A. plumosus and its forms. M. Ed. Pynaert van Geert secured a second prize for an Elk's Horn Fern showing a large and old example of the popular P. alcicorni, this measuring nearly six feet through. The same exhibitor gained a special prize—silver medal—for Polypodium aureum, grown in a tub. M. Pynaert van Geert had to be content with second place for thirty ferns, winning a gold medal with a miscellaneous collection that followed that of the Comtesse de Kerchove.

In a miniature greenhouse, and well closed in from the influence of the drying atmosphere around, M. Arthur de Smet, Ledeberg-lez-Gand, showed a dozen filmy ferns; these were comparatively small, the biggest specimen being an example of the Killarney fern, *Trichomanes radicans*; others were T. Lushnathianum, T. reniforme, Todea superba, a neat example; T. pellucida, T. species, T. plumosa, T. hymenophylloides, Hymenophyllum demissium, H. caudiculatum, and H. flexuosum. The Comtesse de Kerchove was successful for six tree ferns, securing the work of art offered by the council of the society; Cynthea medullaris, Cibotium Schiedei, Cyathea Beireckiana, C. dealbata, C. Smithi and Dicksonia squarrosa; the two latter have very long slender trunks, the Dicksonia being probably nearly twenty feet high. The Messieurs Duriez frères easily came first for a dozen ferns, notable specimens being Adiantum macrophyllum fol. var., A. fragrantissimum, Asplenium Belangeri, and Acrostichum crinitum, the Elephant's Ear fern. M. Ed. Pynaert van Geert secured a silver medal of the first class for twelve pterises, his set containing such comparatively new sorts as P. Mayi, P. Reginæ, P. serrulata gracilis, P. Victoriæ, P. Wimsetti, and P. longifolia Mariesi.

The only group of ten Elk's Horn ferns came from M. J. de Cock, Ledeberg, and included a big example of Platycerium alcicorne, and smaller ones of P. grande, P. Hilli, P. Willincki, P. majesticum, P. bicornis, and P. alcicorne majus. P. Hilli was very good.

Bulbous Plants.

Bulbous plants were plentiful and good. In the six classes provided for hippeastrums the Britishers were delighted to see that Messrs. R. Ker and Sons, Aigburth Nurseries, Liverpool, secured all the first prizes; they arranged a large collection around the salon, and throughout these exhibits great excellence, both of strain and cultivation, was evident. Flowers were round and segments broad, the green bases to the sepals and petals were almost absent, and there was a considerable variety of coloration observable. In the class for forty specimens Messrs. Ker were followed by MM. Krelage and Son, Haarlem, whose plants seemed to have suffered somewhat during transit. Messrs. Ker and Sons took the only prizes offered for twelve amaryllis with a first-rate set, and won the gilt medal for half-a-dozen examples—one form, named Nestor, rich orange-scarlet and white, being of especially good form and size. The work of art offered for the best seventy-five hippeastrums also comes home to Liverpool, and the plants that won it were the centre of admiring crowds throughout the exhibition; nearly every plant in this set carry four flowers per spike, a high percentage. Whatever there was to be won for amaryllis the Messrs. Ker secured easily. Polyanthus narcissi were best shown by M. Kuyk, Mont St. Amand, but they were not above average excellence.

Hyacinths did not strike us as being of special excellence; but those specimens shown by M. Byvoet, and gaining the work of art as first prize for 150 plants in fifty varieties, were moderately good. The best varieties were King of the Blues, Tabista, Leonicas, Cardinal Wiseman, King of the Yellows, King of the Blacks, Moreno (pink), Czar Peter, and Charles Dickens, all popular sorts at home. The Messrs. Byvoet frères, Overveen, had much the best hyacinths in the show, and, besides the set already alluded, they scored for 100 hyacinths, with an even set of very fair merit; La Grandesse, Princess Amalie, Charles Dickens, Grandeur a Merveille, Lord Derby, Bird of Paradise, and Piennmann were the varieties showing the finest spikes. M. Kuyk came second, and M. Van Houtte third; but reversed their order of precedence in the previous class. No particular new variety was to be seen in M. Kuyk's first prize set of fifty narcissi. M. L. Van Houtte was to the fore with small collections of hyacinths. M. Kuyk, Hillegom, won a large gold medal for a large group of hyacinths, staged effectively in pans of separate varieties, ten bulbs per pan, and usually nine to twelve spikes on each; these pans, bedded with ferns, were very effective—Gertrude, Queen of the Blues, Madame Van der Hoop, La Grandesse, and Cavaignac were very fine, as was the yellow Ball of Gold.

M. Kuyk had a bright exhibit of tulips, showing these in pans, ten bulbs per pan; there were thirty pans, so that the blaze of colour can be imagined. A gold medal was awarded. Double tulips were best shown by M. Kuyk, and the varieties were all popular, especially the double Tournesols.

The cyclamen classes were monopolised by M. L. P. de Langhe-Vervaene, Brussels, who made extensive displays of his variously coloured papilio forms, one of which we figured some time since. These show the variation of form that can be evolved from the ordinary type by following up any small break from the usual shape; all the colours save the deepest crimson were seen in M. de Langhe's collection, and he won the gold medal for fifty examples, and also the Williams' Memorial medal offered for the best twenty-five specimens. The papilio cyclamens are quite as floriferous as the commoner forms, but seem scarcely so effective.

Bromeliads.

These interesting plants are extensively cultivated in Belgian gardens and nurseries, and were accordingly very strongly represented. A collection of thirty bromeliads exhibited by M. de la Ruye-Cardon, Ledeberg, was worthy the gold medal awarded. Leading examples were Nidularium rutilans, Caraguata cardinalis, with long scarlet centre; Tillandsia Zahni, with several spikes of yellow flowers; T. splendens major, T. Lindeni, with numerous rich blue blooms; Vriesia Barilletti, Tillandsia tessellata, T. Wartelli, with a long, sword-like scarlet spike; Vriesia Leodinense, with orange and yellow spike, and V. hieroglyphica, with handsome foliage.

MM. Duval et Fils, Versailles, scored for fifteen bromeliads in flower; they were all small plants but well grown, and such as would attract the attention of the curiously-inclined at home. Vriesia Rex, V. cardinalis, and Caraguata Zahni were most interesting. This firm had also the best three bromeliads, a Vriesia Rex superba, a strong form of the type. For twenty-five examples of the same species the MM. Duval put up a little company of Vriesia Poelmanni, a handsome crimson scarlet spathed hybrid between V. gloriosa and V. [illegible] Scepti.

Bromeliads are fairly popular with our Belgian friends, but many of them are not very handsome except when in flower. M. J. Moens, Lede, gained a second prize in the amateurs' class for fifteen specimens. Tillandsia van Volxem and Nidularium argenteo-strealum were good specimens.

Trees and Shrubs.

Trees and shrubs were exhibited in immense numbers, and, arranged for the most part in the grounds, formed a highly interesting feature. Lilacs were especially good, and were associated with the greenhouse plants. MM. Lemoine et fils, Nancy, took premier position for lilacs, staging very pretty plants of President Carnot, blush; Emile Lemoine, double white; M. Jules Finger, semi-double white; Charles Joly, double lilac; Michel Buchner, very large flowers; Abel Carriere, with large branching spikes of pale lilac flowers; Leon Simon, a fine double blush form, were very fragant and handsome. A beautiful bank of Marie Legrange lilac, single white, made a fragrant exhibit from M. L. de Bock, Ghent; they were admirably forced. M. de Bock secured several medals for forced lilacs, and in every case his plants were splendidly flowered.

M. Fred. Burvenich, père, was awarded a gold medal for a collection of conifers; this was a good exhibit, but there wanted some choice variegated forms to enliven the whole; Juniperus sinensis, Podocarpus Koriana, Picea excelsa clanbraziliensis (very dwarf), Abies lasiocarpa, and A. Nordmanni were deserving of mention. This exhibitor showed large numbers of conifers, and won the chief [illegible] everywhere; we could not find, however, any specially meritorious varieties [illegible] new or rare, but the whole collections were of good average quality. Hardy evergreen shrubs were freely arranged out of doors, and in bulk added not a little to the effectiveness of the whole exhibition; they consisted of seedling aucubas, hollies, laurels, enonymuses, buxus, berberis, &c. M. Burvenich set up a really good lot of well-fruited aucubas in pots, both green and variegated forms. Standard hollies were a little out of the common, and the chief collection came from M. Bedinghaus; H. arborea aureo-variegata and H. a. marginata were by far the most handsome, though all those staged were very well grown, from four to seven feet high, and with heads two and a half to three feet through. Four specimen [illegible] laurustinus freely flowered and fragrant, were much admired; these were placed close to the Conpure entrance by M. E. Eeckhart. M. Léon Fretin [illegible] the best standard bays, marvels of patient cultivation, and admirable as such. M. Bernard Spae was responsible for some gigantic phormiums, both green and variegated, and some standard laurustinas full of fragrant white trusses of flowers.

Shrubby plants with ornamental foliage were a feature, and admirably contributed by M. A. de Mayer and M. J. de Cock; Laurustinus aureo-variegatus, Eleagnus pungens medio-picta, Skimmia japonica variegata, Euonymuses in variety, Hedera argentea, aucubas and hollies made up interesting exhibits that suggested we do not take full advantage of coloured foliage for [illegible] and conservatory decoration during winter. The Comtesse de Kerchove secured the first prize for a specimen eriostemon with a bulky example. Big enonymuses came from M. Bedinghaus, and some of the varieties of E. japonicus were immense examples, but fairly coloured. Standard roses from M. C. Vanderhaagen, pére, were nicely flowered, and made up a fragrant exhibit; the varieties were mostly popular sorts.

Greenhouse Plants.

Greenhouse plants, remarkable for the beauty of their flowers, were represented by numerous collections, consisting of specimens so highly developed that they could hardly fail to afford pleasure to those of our compatriots who are interested in hardwooded plants. For a collection of plants introduced from the Cape or New Holland M. E. Collumbien was awarded the gold medal for excellent examples of Diosma fragrans, Correa cardinalis, Boronia hetrophylla, Acacia [illegible], Polygala Dalmaiseana, and other well-known subjects. In the corresponding class for amateurs M. E. Bedinghaus was awarded premier honours. Several good collections were contributed to the two classes for twenty Cape and New Holland plants, and the Comtesse de Kerchove and M. J. de Cock were first in the amateur and trade classes respectively, the premier award being in each case a gold medal. The remarkable beauty of Boronia elatior when grown to a specimen size was admirably exemplified in the collection of twenty plants for which M. Piers, Ghent obtained premier honours. These ranged from two to three feet in diameter, and were profusely bloomed, the bright pink campanulate flowers presenting a pleasing contrast to the elegant bright green foliage.

The King's prize for twenty-five greenhouse plants was worthily won by M. Emile de Cock, Ghent, with a handsome exhibit of large plants of Eriostemon [illegible], Boronia elatior, very graceful and freely flowered; Acacia grandis, a mass of golden balls; Polygala Dalmaisiana; Cymbidium Lowianum, with seven [illegible] spikes; Acacia cordata, bristling with soft yellow flowers; Azalea linearifolia, a mass of pale rose blooms, and in fine condition, such as we do not see it at home; Grevillea Preissi, Medinella magnifica, some azaleas and camellias, made up a fine exhibit. M. Bedinghaus, who was second in this class, led the way for fifteen greenhouse flowering plants, showing towering acacias, a fine [illegible] Chandleri, and a spreading azalea, Marie Van Houtte, six or seven feet across. M. Bedinghaus made a reputation for New Holland and Cape plants, his exhibits reminding one of the olden days, when these subjects were popular in England. He led the way both for twenty and ten specimens, showing large and freely flowered examples of Acacia verticillata, A. linearis, A. arumata, Leptospermum scoparium, Bauera ericoides, Metrosideros semperflorens alba. Standard Cytisus racemosus, ten feet high, and with big rounded heads, a mass of golden yellow, came from M. Eugene de Cock. A splendid standard of Acacia paradoxa from M. C. de Loore attracted our attention by reason of its size. Diosma fragrans is a charming plant with large white flowers, each with red basal vein, was a notable specimen in a group of M. Collumbiens'. Pyramids and standards of Genista alba from M. van Driessche were exceedingly pretty, as shown smothered with small pure white flowers. M. van de Wynckel, Ghent, staged a finely developed lot of Citrus sinensis, the oranges clustering thickly all over the large [illegible]. A set of somewhat small ericas won leading honours for M. de Clerque [illegible]; E. herbacea and its forms, E. Willmoreana and E. arborea odorata were the best of a middling lot. M. Bedinghaus's large standard Polygala [illegible] secured a chief award, but was scarcely fully in flower. Gnaphalium [illegible] from M. Eggremont were curious fine examples of careful culture, but scarcely to our taste. M. Bernard Spae, Ghent, merited a gold medal for araucarias, a speciality in Ghent; he showed varietal forms of A. excelsa, notably A. glauca robusta, the strong A. Bidwilli, A. Cooki, A. gefride elegans, A. Rulei, a stiff grower, and some others. M. Leon Fretin, Mierebeke, also had a fine group, staging smaller specimens of A. Cunninghami, A. Cooki, A. glauca robusta, A. [illegible], and A. Cunninghami glauca.

Aroids.

Aroids were contributed in large quantities, and on the whole well cultivated. The premier group of thirty plants representing as many species, came from that [illegible] cultivator, M. Rigouts, who had fine anthuriums, Aglaonemus costata, [illegible], Philodendron gloriosum, Alocasia pucciana, and Nephythitis [illegible]. For fifteen aroids M. Rigouts again led the way with highly-cultivated [illegible], among which Dieffenbachia Baumanni was conspicuous. M. Louis van Houtte, père, took secondary position here. M. de Smet Duvivier contributed a considerable number of anthuriums, crotons finely coloured, alocasias, and bertolonias, gaining numerous gold medals for the displays. The Société Horticole Gantoise arranged twelve pretty spotted forms of Anthurium Scherzerianum, one named A. Princess Clementine having its spathe very heavily checked with scarlet on a white ground. A new medium-sized Richardia named Perle von Stuttgart came from M. Wilhelm Pfitzer, Stuttgart; it is a compact grower, and rather larger in the spathe than Little Gem,

Dieffenbachias were plentiful in all the large collections, and in the class for ten specimens M. Rigouts maintained his position as a splendid cultivator by carrying off the silver-gilt medal as first prize, with well-coloured examples; the kinds were D. Memoria Corsi, D. Gartneri, D. picta, D. Bowmanni, D. nobilis, D. Fournieri, a pretty plant; D. imperialis, D. Jenmanni, D. magnifica, and D. Bausei; some specimens had as many as ten growths. The best set of fifty caladiums was set up by M. L. van Houtte, pére; they were medium-sized examples, but far too crowded together to be seen to advantage; the best-coloured specimens were of Candidum L'Automne, one of the yellowish green varieties; Louis van Houtte, deep burnished crimson; Ovala, Gabriel Lemoinier, and Raymond Lemoinier, creamy with rosy crimson centre. M. A Dalliere, with dwarf plants, gained a silver-gilt medal as a first prize for caladiums; his varieties M. Bause, M. de l'Aigle, and Countess being the best shown, and each highly coloured.

Miscellaneous.

Bertolonias from M. Dalliere were very handsome, especially the silver and rose-coloured Souvenir de Antoine Chantin and Fr. Marchand; Comtesse de Kerchove, silver and green, Prince Albert, bluish silver and green, were also very attractive. The same exhibitor contributed a yellow variegated form of the now popular Saintpaulia ionantha. M. Jules de Cock sent a good lot of bertolonias highly coloured and most robust. A large example of Nepenthes mixta won for M. L. Van Houtte, père, a gold medal; it carried about fifteen pitchers. The same firm were awarded a gold medal for a collection of nepenthes, but the pitchers were past their best.

Messrs. Vilmorin, Andrieux, and Co., Paris, were large exhibitors of both double and single cinerarias of good form and colour; they also staged a splendidly flowered lot of white Primula obconica that met with much appreciation. Herbaceous calceolarias from MM. Vilmorin gained a gold medal, while the cinerarias and primulas gained their share of leading awards. Tricolor and other coloured foliaged pelargoniums from M. H. de Coninck, St. Denis, were of interest to not a few, Bijou d'Or, Princess of Wales, Crystal Palace Gem, Canary, and Sappho were good golden sorts. while tricolors were represented by Lady Cullum, Alpha, Countess of Graiz, Sophie Dumaresque, and Mrs. Pollock, the two last being the most handsome.

Dracæna Goldieana was superbly shown by Messrs. De Reuse frères, Ghent, who staged twenty-five splendidly coloured specimens, bedded in asparagus. For this display they justly gained a first-class silver medal as first prize for the best coloured dracænas. Some magnificent specimens of Dracæna Doucetti were staged, and these were four and five feet high, and furnished to the ground with handsome leafage; M. G. Gyzelinck had the best pair, but there was not much to choose between the second prize pair, and we have never seen finer specimens.

Aralia leptophylla is an imposing plant when well grown, and its inflorescence, if not adding to its beauty, does to its interest; a big specimen was shown by M. G. Gyzelinck, Melle.

Succulents were poorly represented, though M. Bedinghaus obtained the large gold medal for the best collection of twenty-five specimens. There were some good yuccas here, but the agaves looked starved.

Non-Competitive Exhibits.

A magnificent group of hippeastrums came from Messrs. J. Veitch and Sons, Chelsea; the variety in colour was especially observable, the white grounds being of especial note; some of the blooms gave evidence of somewhat hard forcing, but on the whole it was a brave show, and delighted the eyes of our continental friends. In addition to the hippeastrums the Messrs. Veitch made a fine show of nepenthes, sarracenias, and other pitcher plants, including Heliamphora nutans, Cephalotes follicularis, Darlingtonia california; the pitchers of the nepenthes were remarkable for their size and production at such an early month of the year; N. Dicksoniana, N. Veitchi, N. mixta, N. formosa, N. cincta, N. ampullacea, N. Burkei excellens, N. Curtisi, N. Mastersiana, and N. sanguinea were among the finest of the specimens staged; a few droseras, ferns, and asparagus furnished an edging and groundwork to this splendid exhibit.

Carnations were well shown by Messrs. W. Cutbush and Son, Highgate; the varieties were principally Souvenir de la Malmaison forms, Winter Scarlet, Daybreak, and E. G. Hill. A few palms formed an admirable background for a dozen and a half flowering specimens of Richardia Elliottiana.

An extremely interesting group was the large and fine display by Messrs. Linden and Co., L'Horticulture Internationale, Brussels, and set up to show as far as possible the comprehensiveness of the late Mons. Jean Linden's introductions. To mention a quarter of the species displayed would occupy far more space than we can spare, and would serve no useful purpose at the present time. We may remind our readers, however, that they are indebted to M. Jean Linden for such well-known plants as Bignonia Rodigasiana, Caraguata cardinalis, Leea amabilis splendens, Cocos Weddelliana, Spathiphillum floribundum, Dioon edule, Phyllotænum Lindeni, Gunnera manicata, Anthurum magnificum, Dichorisandra angustifolium, Stenandrium Lindeni, Maranta majestica alba, Cyanophyllum magnificum, Tradescantia superba, Dracæna Lindeni, Maranta illustris, Iresine Lindeni, Hæmanthus Lindeni, Acalypha triumphans, Fittonia argyroneura, Anthurium crystallinum, Odontoglossum cirrhosum, O. luteo-purpureum, O. Pescatorei, O. crispum, O. triumphans, Cattleya Mendeli, C. labiata Warocqueana, C. Trianæ, and Miltonia vexillaria, in addition to very many fine palms and large growing stove plants such as find a place in all well-appointed gardens. Aralia gracillima was one of M. Linden's finds.

A big specimen of Cyntodeira fulgida, grown in the shape of an armchair, was sent by M. A. Dalliere, Ghent. This was a remarkable case of patience put to a poor use.

Autumn-sown Onions.—"A. D." is quite right, as far as our experience goes, in surmising that the harder brown skinned varieties of onions, if sown in the autumn, will keep a great deal longer than the Tripolis. We have had bulbs a pound in weight of Sutton's A 1 grown from autumn-sown seeds and as sound as possible in January. How much longer they would keep I cannot say. In the event of a very mild season, as a preventive to bolting, we have found it answer well to transplant in autumn instead of waiting till spring.—C. J. Dicker, *Frant Court.*

SOME ROSES OF 1897.

In considering the merits of roses sent out for the first time some ten months ago, it is obvious one can only judge of them principally as seen at the exhibitions, or, in the case of British-raised roses, as set before us prior to being distributed. Now it has been proved in more than one instance that however good a rose may appear whilst in the hands of the raisers, and coming from the climate and soil where it is at home, a very different account of the rose may be given when tried in another climate and in other hands. Messrs. Dickson and Sons will pardon me, I am sure, for giving as an example Margaret Dickson, a gold-medal rose, which they have staged, and continue to stage, so well. With us in the south it makes long, coarse growth, with many blind shoots, and a flower only here and there, but too thin, too hollow to be of any use. It may be our mismanagement, but we have patiently tried it on manetti and briar, as maidens and cutbacks, and hoped on year after year; but now we have given it up as quite useless to us, so that in dealing with roses of 1897 we can only in some cases give first impressions, and for the most part must fall back upon the raisers' descriptions.

Countess of Caledon, H.T. (A. Dickson and Sons) has been before the public since 1895, when it was awarded a card of commendation at the National Rose Society's show at Derby. Probably by reason of its colour and general character it has not been awarded a gold medal, nor has it won such universal favour as Mrs. W. J. Grant in 1894, or Ulster in 1897. Messrs. Dickson state that Countess of Caledon "is a magnificent variety of undoubted merit, alike useful for exhibition or decorative purposes. It is of vigorous growth and free branching habit, flowering in great profusion throughout the entire season. The blooms are large, of great substance, and perfect form, with large stout petals; colour, rich carmine rose; splendid."

Empress Alexandra of Russia, T. (William Paul and Son).—This rose was well staged by the raisers at the Manchester Rose Show last year, the judges deservedly awarding it a certificate without hesitation. In colour and habit it reminded one of that old copper-coloured rose, Ophirie, but of much better shape. Some of the flowers were not very well formed, but others were decidedly good and well up to exhibition standard of excellence. Considering that this is its first year, one must not be too exacting as to form and substance. I think it will turn out to be a very good rose. From its distinctness in colour and freedom in flowering it will be useful for decorative purposes. The raisers describe it as "rich lake-red, shaded with orange and fiery crimson; very large, full, and globular; of vigorous growth, fine foliage, and great freedom in blooming; a most distinct and effective tea rose, splendid also for pot culture and late autumn and winter blooming. Plants in full bloom exhibited by us at the Royal Horticultural Society's meetings on November 26, 1895, December 15, 1896, and March 9, 1897, received a silver Banksian medal and an award of merit, and were universally admired by all visitors present on those occasions."

Mrs. Frank Cant, H.P. (Frank Cant and Co.).—I can speak more decidedly of this rose than of any of the others in this list, having seen it, not only as staged at exhibitions, but also as growing in Mr. Frank Cant's rose grounds. There it was sturdy and upright in growth, vigorous, and bearing well-formed flowers of good substance, quite distinct in colour. As far as my knowledge of it goes, I can fully endorse the raisers' description of it, which is as follows: "This is a charming new rose distinct in every way from all others. Its colour is a beautiful clear pink, the edge and back of petals silvery white, while the base of the petals are fully two shades deeper in colour. The flowers are large, very full, perfectly formed, and produced abundantly, every shoot bearing a flower. Its habit of growth is erect and vigorous. Not only is it a valuable exhibition rose, but also one of the finest pot roses in cultivation. Exhibited at the Royal Horticultural Society it gained an award of merit. Exhibited at the Crystal Palace National Rose Society Show, card of commendation.

Miss Ethel Richardson, H.P. (A. Dickson and Sons), has been exhibited by the raisers several times last year, and if my memory serves me true, some good flowers were staged in the open treble class at Trentham last season. As a white or blush H.P., it is quite distinct. The growth did not appear to be very strong. The raisers' description is as follows: "This superb rose is thoroughly distinct from anything extant. It is of moderate growth and free-flowering habit. The flowers are of very large size, imbricated form, with high centre, the petals large, smooth, and slightly reflexed; colour almost pure white, with pale flesh centre. As an exhibition variety, we feel confident this rose will take high rank."

Robert Duncan, H.P. (A. Dickson and Sons), is one of the set of three new roses sent out last year by this firm. The raisers tell us that it is another very distinct and fine hybrid perpetual, of vigorous growth, flowering abundantly. The blooms are large, perfectly formed, and of good substance; petals large and shell-shaped; colour bright, rosy lake. highly meritorious variety either for garden decoration or exhibition purposes."

There are also three summer-flowering climbing roses, announced as "The Three Graces," and said to be companions of Turner's Crimson Rambler, but I have not seen them. They are thus described:—

"Aglaia (Yellow Rambler).—Bright orange yellow, a vigorous climber, producing large bunches of flowers; highly spoken of in Germany and America." An illustration of this rose climbing up a wall is given in Messrs. Paul and Son's catalogue. It looks a very handsome rose.

"Euphrosyne (Pink Rambler), with large bunches of small pink flowers."

"Thalia (White Rambler).—Very large bunches of white flowers."

There are a few other roses of 1897, some of which have been seen at last year's exhibition, but of which it will be sufficient to give the names and descriptions as taken from the trade catalogues.

Enchantress T. (William Paul and Son).—Flowers creamy white slightly tinted with buff in the centre; large, full, and globular, the petals slightly recurved at the edges; of vigorous growth, fine foliage, and great freedom in blooming; a most distinct and effective tea rose, splendid also for pot culture and late autumn and winter blooming. Messrs. Paul go on to say: "Plants in full bloom, exhibited by us at the Royal Horticultural Society's meetings on November 26, December 15, 1896, and March 9, 1897, received silver Banksian medal and award of merit, and were universally admired by all visitors present on those occasions."

Ferdinand Batel, H.T. (Pernet et Ducher).—"Colour varying from pale rosy flesh to nankeen yellow; flowers fair size, very free blooming."

Ferdinand Jamin, H.T. (Pernet et Ducher).—"Rosy carmine, shaded salmon, large well formed flowers."

Marguerite Appert, H.T. (Vigneron)—"Bright red, very large flower of full and globular form."

Madame Cadeau-Ramey, H.T. (Pernet et Ducher).—"Rosy flesh, shaded with yellow at the base and bordered at the end with rosy carmine, flowers large and full, very promising."

The Rev. Allan Cheales, H.P. (Paul and Son).—"A large pæony-like rose. of extraordinary novelty and beauty of colour, pure lake with reflexed silvery-white back petals; an early and late bloomer, producing large masses of its vividly-coloured flowers. Very vigorous, with handsome blue-green foliage. A cool season exhibition rose, and as a garden rose excellent for bedding in masses. Named in compliment to one of our oldest amateur rosarians. It proves to be finest rose-coloured forcing H.P."

Waltham Standard, H.P. (William Paul and Son).—"Brilliant carmine, shaded with scarlet and violet; opening flowers very vivid in colour, with fine stout petals keeping well to the end; shape and petal of A. K. Williams; of vigorous growth and fine foliage. A grand exhibition rose, and also one of the best for garden decoration."

Joseph H. Pemberton.

BOMAREAS.

Those members of this genus now in cultivation form some of the most ornamental of our climbers for the warm greenhouse. They are natives of the mountainous regions of south-western America, and many are found at extremely high altitudes. In the "Handbook of Amaryllideæ" as many as seventy-five species are described, but a very small proportion of these are to be found under cultivation; indeed, they are very seldom to be seen outside of our botanical gardens. Considering the little difficulty attending the cultivation of these free-growing plants, and the charm possessed by them when in bloom, it is a matter for wonder that they are so often neglected. The roots are tuberous, and swell out to a considerable size, and being of quick growth require a substantial soil for compost, and they succeed well in borders given good drainage, the latter being a great point in their culture. The elongated stems grow to various lengths, usually to ten or twelve feet or more, while the foliage borne along these is of an acute oblong shape. At the termination of these growths are formed the inflorescences, and if they are allowed to hang for several feet from the roof they are shown to best advantage. The best results are attained when the growths are trained upon single strings or wires, as no crowding then occurs, and each stem receives all the light possible. At Edinburgh they are planted upon the stage in the cool end of the Succulent House, and in this manner, as at Kew, they are found to do well. To pot culture they do not take kindly, and it is far better to prepare a bed of soil for them in the most suitable spot available than to attempt to grow them in pots, for in the latter they have generally the appearance of being starved.

Just now there is flowering here Bomarea patacocensis, which for some time enjoyed the synonymous name of B. conferta. This is undoubtedly the gem of all the species in cultivation, and at the same time one of the strongest growers. When seen in good condition, with several of its large umbels carrying twenty to thirty flowers each, and in such condition as it grows here, at Kew, and at Trinity College Gardens, Dublin, it is not readily forgotten. In August of 1896 seedlings were sent here by Mr. F. W. Burbidge, and these are now flowering, the rich crimson colour rendering the umbels conspicuous. This species is figured in the *Bot. Mag.* t. 6,692, and was introduced about 1882 by Messrs. Shuttleworth and Carder. B. Carderi is also a fine plant, with a compound umbel which, upon strong plants, forms very large heads of bloom of a loose habit. An inflorescence of this lasts for several months in flower. The leaves of this species are glabrous. In colour the floral segments are pale pink spotted with brown. One of the most prolific species is B. frondea; it produces dense flowered umbels of reddish [illegible] blooms, and flowers over a considerable period. The habitat is at from eight to ten thousand feet elevation on the Andes of New Granada. B. oligantha is a native of the Andes of Peru, and produces slender [illegible] with umbels of only six to eight flowers, these being of a dull red [illegible]

Bomarea edulis chontalensis is a pretty variety, found by [illegible] the outskirts of the woods in the Chontales Mountains of Nicaragua, and introduced in 1871. It has a branched inflorescence [illegible] unequal spreading peduncles, and the blooms have a rose-red [illegible] and yellowish inner segments. Other species are B. caldasiana, a [illegible] coloured plant and a free bloomer; and B. ærtifolia, a slender [illegible] species from Mexico, the colour of the flowers being a pretty combination of yellow and red. The temperature maintained where these plants are grown should be above that of an ordinary greenhouse, yet [illegible] requires to be grown in a stove—as they may be sometimes seen—and a free circulation of air is required to grow these handsome [illegible] well.

Royal Botanic Gardens, Edinburgh.

R. L. Harrow.

SCARCITY OF LATE PEARS.

[illegible] correspondent, Mr. G. Wythes, does well in calling attention to this important subject, for there are many varieties of pears catalogued as [illegible] in season from January till April, and yet few of them are found to [illegible] good condition after the turn of the year. That soil and situations have much to do, not only with the time of ripening, but also with the [illegible] of pears, all who have had much experience in their cultivation will admit; and also that seasons vary, and cause a considerable difference in the time many of them are available for use. Still, it is puzzling to discover how nurserymen compile their lists. If they were compiled years ago, when many of the varieties were grown as standards in open orchards, then one could understand that there would be a difference in their time of ripening, as many were grafted on the pear and white thorn stocks; but now the quince is mostly used, and being shallow rooted, the fruit doubtless matures much earlier, and though they may seem hard at the time of gathering, they soon change, even when kept in a very cool place.

We will take, for example, Beurre Diel. I have had fruit of this variety, a pound in weight each, gathered from espaliers, which kept in good condition till the middle of January. The fruit was allowed to hang on the trees till the middle of October, and then stored in a cool place. Here, in the south, the fruit is seldom good after the middle of November, even when the greatest care is taken in gathering and storing. Forrelle refuses to grow with me in any position, yet in some gardens this is a fine variety, of both excellent flavour and appearance; in North Wales I grew it against a south wall, and grafted on the pear stock, and no pear could have been finer in flavour at the end of January. Hacon's Incomparable was also very fine on the light sandy soil in the district above referred to, but here, even against a south wall, it cracks, and is of no use. Glou Morçeau, on the same warm, sandy soil was excellent. Gathered the second week in October from cordon and espalier trees, the fruit remained in good condition till the end of January; but here, on a cold, stiff soil, the fruit cracks badly, and what few are perfect usually ripen about the middle of November. Ne Plus Meuris, grafted on the pear, and grown as an espalier, was excellent on the warm, sandy soil in Denbighshire; but here the fruit is of but little value; there fair-sized specimens were obtained, but here in the south they are neither so large or of such fine quality. Winter Nelis, a fine old pear that should find a place in every garden, as it is of first-rate quality, and though not large, will usually give a crop of fruit. At Buxted it ripens too early, especially when grown on the quince, for though we had a good crop last season, the fruit was all ripe in November, not a specimen being left even till the following month, though they were not gathered until [illegible] late in October. Zephyren Grégoire is a fine-flavoured variety, but like Winter Nelis, is only of medium size, and therefore finds but little favour with those who grow only for exhibition. In favourable seasons this will keep good, even in the south, till January. Van Mons. Leon le Clerc, when grown on the pear stock, is particularly fine; I have had specimens weighing eighteen ounces that have been in grand condition in the middle of January, but in some seasons, and on cold, stiff soil, it is most unsatisfactory.

Jean de Witte, when grown on the pear stock, will keep in condition fully two months longer than when grown on the quince. This fine old pear is not thought so much of nowadays, since all the rage has been for huge fruits, but if flavour is to count for anything, then both this and Passe Colmar should have a place. Bergamotte Esperen is another medium-sized variety that does not find so much favour as it ought; the tree is not a strong grower, but the fruitfulness of this variety should commend itself to all. Like most others, however, when grown on the quince the fruit ripens fully a month earlier than it ought. Like Mr. Wythes, I am greatly disappointed with Le Lectier, and with me the fruit was early ripe in December, and of but second-class quality. The only thing in its favour was size. President Barabe was fairly good, but could not be considered first-class. I have never yet eaten a good fruit of Beurre de Jonghe, for here they go woolly before fully ripe, and even in the most favourable seasons it will not keep beyond the middle of November. Beurre Rance is often so gritty as to be almost worthless, though in favoured situations, and on warm, sandy soil, the fruit is fairly good. On the cold soil here it is quite worthless. Chaumontel, grown against an east wall in some seasons, is quite passable, though in others the fruit is poor and gritty; even at the best it is seldom we have been able to keep it till January. Easter Beurre is usually good, though in [illegible] autumns this is also liable to crack; still, as a rule, it is one of the [illegible] late varieties we have. Josephine de Malines is sometimes very good, especially when grown against an east wall. On the pear stock this [illegible] does better than on the quince.

The question now is, Are we not by growing pears on the quince [illegible] bringing them more quickly into maturity, causing the fruit to ripen earlier than when grown on the pear stock? if this be so, then the remedy is as bad as the disease, for though we may have more fruit at an earlier date, we sacrifice more than is gained by being without good pears when dessert of any kind is scarce. I should be glad to know what others have to say on this subject, as it would be very interesting to hear their experience. Most of us know that, by allowing the fruit to hang as long as possible, it will retard its ripening, but with respect to the various kinds of stocks used to play such an important part, it would be more interesting still to have opinions.

[illegible] Park Gardens.

H. C. PRINSEP.

THE BEST GUIDE to the garden for the whole year is the "Gardening Year Book," [illegible] articles on the cultivation of Flowers, Fruit, Vegetables, &c. Price 1s. "Gardeners' Magazine" Office, 4, Ave Maria Lane, London.—[ADVT.]

WORK FOR THE WEEK.

WARM ORCHIDS.

THE repotting, top-dressing, and re-basketing must be proceeded with, as the season is advancing rapidly for this kind of work for many species and varieties. The dendrobiums generally that require a warm temperature will have in most cases finished their season of flowering (except in cases where they have been retarded for exhibition and other purposes), and must receive general attention and be placed in their growing quarters, after being well sponged over with soft-soap water and loosely tied to neat sticks. Where grown in pots, a mixture of fibrous peat with all the small dust shaken out, the best sphagnum cleanly picked and washed, a little charcoal and broken crocks will suffice. The plants must be kept well above the rim of the pot, and the pots used must be as small as possible, according to size and condition of the plants. Green fly is a great pest at this season and attacks the young growths and flowers, so a fumigating with XL All will be necessary occasionally. The roller blinds must be used to keep the atmosphere humid, as root action is now vigorous. Dendrobium fimbriatum and its var. oculatum, D. thrysiflorum, D. chrysotoxum, D. suavissimum, D. aggregatum, D. densiflorum, D. Jenkinsi, and others in this section will in some cases have finished flowering, and now require also repotting, &c.; these should not be repotted unless they really require it, as often a top-dressing is quite sufficient. Cattleya minucia, C. Ashtoni, and C. Johnsoni—the result of a cross between C. Harrisoniæ and C. gigas—will first be commencing their new growth, and if any of these require attention they must receive it at once. Pot-shaped baskets are the best to use, suspending these from the roof along with the rest of the choice cattleyas, lælio-cattleyas, &c. Cattleya Harrisoniæ, C. amethystoglossa, C. guttata, C. Leopoldi, C. velutina, and C. Forbesi, will all require top-dressing or potting. Cattleya Skinneri will probably be flowering and must receive less water, as it is liable to damp; the driest place in the house ought to be chosen for it. Cattleya Bowringiana will now be rooting fast, so more water must be afforded. Cockroaches, woodlice, and slugs must be well kept down in the cattleya house, otherwise they will eat off all the roots. Cattleya Mantini (now a general favourite with orchid growers, especially its var. nobilio), the result of a cross between C. aurea and C. Bowringiana, thrives well in a basket suspended from the roof, and if not already attended to must receive attention forthwith.

Oncidium sphacelatum and O. sphacelatum majus may be grown in any warm house kept at 55 or 60 degrees during the winter months; and it may be found in almost any amateur's collection, and is one of the easiest of orchids to grow; it will now be showing flower, so a few more degrees of heat will assist it. Those that are failing to flower and require repotting should receive immediate attention, and the compost should consist of rough fibrous peat, sphagnum, a little charcoal, and a little silver sand; the pots need to be drained half their depth with clean crocks, and tied firmly down with a few sticks. Sufficient water must be given to keep each bulb plump. Oncidium flexuosum is another old orchid, and when a place suits it well it should not be removed; it thrives well suspended in square baskets in the store in a compost similar to that advised for O. sphacelatum. Thrips and red spider trouble these, and the syringe ought to be used about them on favourable occasions. More damping will be required now, and shading will also require attention; pests will trouble us very much, so fumigating must be done occasionally as a preventive. The temperature may rise a few degrees all round, but the ventilation must be well watched to guard against cold draughts by night and day.—THOMAS STAFFORD, *Tyntesfield Gardens.*

CONSERVATORY AND GREENHOUSE.

AT no other season of the year is it necessary to use so much discretion in affording ventilation to these structures as now and for the next few weeks. At the time of writing there is bright sunshine, which quickly raises the temperature, but as a searching east wind is also prevalent it would be better to let the temperature rise somewhat higher than usual than to open the ventilators for an inrush of cold air. For the most part plants of all descriptions have either been repotted recently, or are developing young and tender foliage, therefore anything approaching a draught through the house would prove anything but suitable to the well-doing of the plants. Fresh air for a short time daily, whenever the weather is favourable, is necessary to encourage clean healthy growth, but until the outside conditions become more balmy, this should be admitted from the highest point of the house, using the side ventilators with caution. The desired temperature is more easily secured, and a nice growing atmosphere maintained by turning off artificial heat, early on bright mornings, and dewing the stages and other parts of the house with tepid water several times during the day. We are not in favour of using heavy blinds for shading greenhouse plants generally so early in the season, as this is apt to promote weak growths; a temporary screen, however, will now be necessary at mid-day, especially for plants in full bloom and also those whose roots have been disturbed. It is undoubtedly the best and neatest way to shade palms, camellias, &c., growing in lofty houses, to paint the roof-glass over with summer cloud, or some other mixture which will not wash off readily. This saves much time and trouble, as the plants enjoy both shade and moisture; a permanent shade, until the autumn, proves an advantage in every way. Established palms, tree ferns, and the like planted in the borders of the conservatory will require copious waterings from now onwards, and the syringe should be freely used about the stems and fronds of tree ferns, to ensure free and clean growth. Hanging baskets from the roof should be gradually watered more freely as the occupants become established, as anything approaching dryness at the roots now would probably lead to failure.

The greenhouse rhododendrons are among the finest plants grown, and may be had in succession by means of gentle forcing. On no account should much heat be employed or a scarcity of moisture in the atmosphere be allowed, as thrips would probably attack the foliage and the blooms fail to open properly. To keep the plants uniform, pinch out the points of those shoots not set with flower buds. Another class of plants that might be grown side by side with these are the daphnes, as the same treatment suits both. Neither will survive coddling for any length of time, and to keep them in robust condition, syringe them liberally during fine weather and admit plenty of air, closing the house early while they are making new growth. Now is a good time to pot these. Clean pots, carefully drained, are necessary; and the compost should consist of good fibrous loam, one-seventh of decayed manure passed through a fine sieve, and coarse sand—a liberal quantity of the latter should be used, and press the compost firmly round the roots. Plants that are in a good condition at the roots, but somewhat straggling in habit, may be pruned into shape. They will break freely if not over-watered and the tops kept syringed. Autumn-struck cuttings of marguerites should be potted on as required, using old potting soil to ensure sturdy growth and plenty of bloom. Unless small decorative plants are required early, pinch out the flower buds as they show, until within a few weeks of when required; as the pots become filled with roots, use soot water, which gives substance to the bloom and deep colour to the foliage. Cut back cytisus as they pass out of flower, and as new growth appears, repot them if necessary, standing the plants in a warm, shady, and moist position for a few weeks, afterwards, gradually hardening them to more sun and air.—RICHARD PARKER, *Goodwood Gardens.*

THE FLOWER GARDEN.

BY the time these notes appear the supply of flowers of the violets will have become exhausted, and as soon as possible after the plants should be taken up, divided, and replanted. With most varieties there will be an abundance of runners or young plants already formed for making up the new plantations. Any old plants or surplus young ones not required should be planted out in odd corners, or by the sides of woodland paths, the old Czar variety being one of the best for this purpose. For the new plantations, or beds, from which a supply of fine violet flowers are required, a piece of fresh ground should be annually given that has been previously prepared by deep digging, and the incorporation of a good dressing of thoroughly decomposed manure. If newly dug it should be trodden over and made firm before planting. Put the young plants out about a foot apart each way, and if the weather be dry, an occasional watering, and almost daily sprinkling overhead towards evening should be afforded until they are partially established. A mulch of old mushroom bed manure or leaf mould is of much assistance in dry weather, when red spider is liable to attack the foliage if the surface soil is allowed to remain dry for any length of time. Any spare spots near walls, with a south-west or north aspect should also be utilised in order to forward and prolong the supply of flowers as much as possible. Several fine single varieties have been sent out during the past few years, Princess of Wales is a grand variety, very free and a large flower, with a good stout stalk, a decided acquisition. Amiral Avellon and California are also strong-growing varieties, but, as far as my experience goes, not equal to the first-named variety for free blooming and sweetness combined. Wellsiana and the Czar should also be grown, while Rawson's White is the best single of that colour. The double varieties are not so generally grown and flowered outside, but during the past few winters plants have stood the weather fairly well, and flowered freely. New beds of lily of the valley may yet be made up, the crowns being somewhat late in starting this season. Where these have become thick and matted together, so that small flowers spikes result, they should be lifted, the crowns sorted over, planting the smaller by themselves, if required. The site of the new beds should have been trenched and manured freely, as a frequent renewal is not necessary. The selected crowns should be planted in sloping drills, chopped out with a spade, about four inches apart, allowing about half the space in the row, press the soil firmly against the crowns, which should be kept just under the surface, and afterwards give a slight mulch of old mushroom bed or similar short manure. West and north borders are the best adapted for lily of the valley culture, those on the north aspect forming a succession to the others.

During this and the coming month the planting of aquatic plants, as water lilies and similar subjects, is best carried out. Considerable attention has been given this style of gardening the past few years, partly caused by the introduction of the fine varieties of nymphæa, by the French raiser, M. Latour Marliac. These are quite hardy, and may be trusted to withstand our most severe winters. With the addition of the bright-coloured varieties of this raiser, including purple, rose and pink in various shades, also sulphur yellow, a good choice in colour is now obtainable, and where the necessary depth of water can be obtained, these may be added at a moderate cost. Where the pond water is from two to four feet deep is a suitable position, with a deposit of mud a few inches in depth. The best method for starting their cultivation is to plant the roots in shallow baskets containing about a bushel or more of soil, consisting of fibrous loam and one third leaf-mould mixed together. The roots may be fastened in with wire or string, and before submerging the basket lay a few stones over the surface of the soil. It is almost useless planting where swans are kept, as they pull off the young leaves and otherwise destroy the plants; water rats are also sometimes troublesome. The pruning and planting of roses and shrubs, &c., should ere now have been completed, and plants of the former may with advantage be given a mulch of half-rotten manure. The hardening off of bedding stuff should receive due attention. Pelargonuims may with safety be transferred to cold pits, or skeleton frames, and be given temporary protection when necessary. Where small plants of golden pyrethrum are required for edging or carpet bedding, seeds should be sown thinly now in frames on a slight hot bed. The planting of the main batch of gladioli should be completed forthwith, the corms deteriorate if kept later out of the ground. Beds or borders filled with carnations may have gladioli planted between them, to flower after the former are out of bloom, they will be of little inconvenience to the layering of the carnations. Bare spots on lawns may be renovated now during showery weather, by sowing grass seeds in suitable mixture, adding a little fine soil after, and pressing firm with a moderately heavy roller.—C. HERRIN, *Dropmore Gardens.*

HARDY FRUITS.

IT may appear strange to advise watering hardy fruit trees at this time of year, but in some soils it is necessary; for instance, a shallow soil resting on gravel is so soon drained of moisture that it needs earlier supplies than some think, and in many cases its application would prevent loss of fruit by dropping. At the time these notes are penned we have still an insufficient rainfall, and having a thin shallow soil, it has been necessary to give newly-planted trees, under walls with a good coping, several waterings; these trees were planted late, and we gave moisture freely to prevent the bark shrivelling. One thorough watering is better than several small ones, especially if a mulch of short manure is given, as this retains the moisture and promotes new root action. Not only do wall trees benefit by the mulching, but those in the open also, as their roots will not then suffer from drying winds. It is necessary to plant many fruit trees shallow to prevent the roots going too deeply, and a mulch now will benefit such. I am not in favour of heavy dressing of wet manure, as this does more harm than good at this season. After the severe gales we have experienced of late, it will be necessary to attend to the supports and ties of young trees. For some weeks past, previous to the flowers opening on wall trees, we gave our fruit trees in sheltered places the overflow from tanks of both liquid manure and rain water, as there are few fruits but what are thus benefited; this with a mulch now keeps matters right for a long time. I am adverse to heaping up large quantities of material over the roots, but some short strawy manure which lies lightly is useful. Trees on sloping banks may have better material, as it will be neeessary to keep the roots cooler, and in sandy soils cow manure, if partially dried, is an excellent mulch and fruit trees like it greatly. In heavy lands such aids as spent mushroom, manure or old hotbed materials may be used for surface dressings.

Some weeks ago I mentioned the necessity of giving fig trees on walls more exposure if the growths were not crowded last autumn and were well ripened; in this neighbourhood we have had no frost since to injure growth, and there will be no need for further protection, but if pruning has been delayed it is well to have the work completed. With an ample supply of young shoots there will be too much wood, and it is well to lay in the new wood wherever possible, removing the old bare growths, which often make many weak shoots that unduly crowd the tree. Some of the longest and naked branches should be clean cut out, or at any rate cut to a healthy shoot. I prefer close training in to the wall for figs, as the fruit is earlier and of better quality; six to nine inches should be allowed between strong fruiting shoots, as the leafage is large and the wood soon suffers if shaded. With old trees there will be a need of thinning out some of the older weak shoots to prevent crowding, as the best fruits will be produced on well-matured wood of last year and not on the small weak spray growth. Sucker growths at the base should be removed, though at times it may be well to secure a well-placed one to replace a poor leader. Now is a good time to plant fig trees on open walls, but such should not be too forward. Few varieties are superior to the White Marseilles, Brunswick, and Brown Turkey; many prefer the latter, but so much depends upon the locality. Near the south coast the fig tree does grandly in the open, especially the Brunswick, but for walls I find Brown Turkey specially suitable; whatever variety is grown, guard against a rich soil or manures at the start, or grossness will result. Figs succeed best in chalky soils, and where chalk cannot be given I have found a liberal quantity of old mortar rubble mixed with fairly strong loam and a liberal quantity of wood ashes is a good compost; for enriching poor soils use bone meal freely in preference to animal manure. If the land is wet or clayey well drain the same, but make the portion near the roots as hard as possible to prevent them going downward; this can be done by thoroughly ramming the materials used for drainage. If the trees have been grown in pots, it will be necessary to spread the roots out, as with pot trees there is a tendency for roots to go downwards, and this must be avoided. Mulch after planting, and give ample moisture in dry weather.—G. WYTHES, *Syon Gardens.*

VEGETABLES FOR EXHIBITION.

RADISHES.

THE difference between a properly and badly grown radish (*Raphanus sativus*) is most apparent. When radishes are well cultivated and brought to the table at the right time they are generally liked, while they make a wholesome and refreshing salad during spring and summer. On the contrary, radishes that are produced on poor soil are a long time growing, and so become indigestible and scarcely fit for human food. To produce radishes of the best quality at all times the ground should be moderately rich, deeply dug or trenched; that which has been manured heavily the previous season is best, and the crop at no time should be allowed to suffer for want of water. The earliest supplies should be produced on gentle hotbeds when a constant supply is required, and should be sown in small quantities about every ten days; we practise sowing some each time when planting potatos or sowing carrots in pits and frames, scattering the seed thinly broadcast after the potatos are planted, and in the case of carrots drilling between the rows. These will be ready before the potatos require to be earthed up, and do no harm to the carrots. For a succession, turf pits, skeleton or cold frames, where they can be easily protected against frost, are suitable, after which warm, snug parts of the garden will suffice. It is surprising what large quantities are cultivated by our market gardeners and the ready sale they find for them, especially when produced early in the season, when they are most remunerative. I am well acquainted with one man who depends chiefly on this crop for a living, and he is generally first in one of our large markets; he commences to sow as early in the year as the weather will permit, protecting the seed with straw until the young seedlings are above the ground, after which, in the event of a sharp spell of frosty weather, pea-sticks are laid over them, and a thin layer of straw on these, the whole being carefully removed on all favourable occasions, and only very rarely are these early sowings a failure.

During the hottest part of the summer, when radishes are often wanted, some little difficulty will be experienced in producing them fresh and good unless grown in a shady cool part of the garden. A north or north-east border is a capital site for growing them during July and August. If sown about every ten days through the spring and summer, and kept well supplied with water, little trouble will be found in keeping up a constant supply. The seed may either be sown broadcast or drilled, the former I prefer. The seed in either case should not be sown thickly, for not only is this a waste of seed, but good radishes cannot be grown [illegible] overcrowded. Small beds should be marked out, and the seed [illegible] buried with the rake, and protected thoroughly against birds. There are now many excellent kinds in the market, including long olive and turnip-shaped varieties well adapted either for forcing or outdoor cultivation. But the two kinds I recommend for general cultivation [illegible] Wood's Frame for early use, and French Breakfast for later [illegible] both old but first-rate varieties.

In staging a collection of salad, not only are well-grown radishes indispensable, but they are very attractive, and help to brighten up the exhibit, and in a miscellaneous collection of vegetables several kinds should be included, for when neatly and judiciously arranged they form a pleasing feature. At all times and for all purposes radishes should be pulled when quite young, and for exhibition should be thoroughly [illegible] and tied up neatly, the long kinds in fan-shaped and the [illegible] turnip sorts in round bunches; about twelve of the former and [illegible] of the latter make suitable-sized bunches. It is a good plan to [illegible] in pieces of damp muslin during transit. For winter use the [illegible] known as Black Spanish is often grown; it should be sown [illegible] August in drills one foot apart, and thinned to eight inches. T[illegible] should be taken up early in November and stored in sand [illegible] when they can be taken out for use as required. Some [illegible] a liking for these, but personally I do not consider them worth cult[illegible] E. [illegible]

Aldenham House Gardens.

HUMUS IN ITS RELATION TO SOIL FERTILITY.

(Concluded from page 251.)

Humus and the Water Supply of Crops.

A SOIL rich in humus not only absorbs more water, but holds it more tenaciously in time of drought than a soil poor in humus. In fact, this is one of the most important differences between soils rich in humus and those poor in humus. A soil which by long cultivation has lost half of its total humus will show a loss of ten to twenty five per cent. of its water-holding power. These differences are well illustrated in the following table, compiled from data obtained in the examination of two typical Minnesota soils :—

WATER CAPACITY OF SOILS CONTAINING DIFFERENT AMOUNTS OF HUMUS.

	Water.		
	In original soil.	After 10 hours' exposure to the sun.	Loss
	Per cent.	*Per cent.*	*Per cent.*
Soil richer in humus (3.75 per cent.)	16.48	6.12	10.26
Soil poorer in humus (2.50 per cent.)	12.14	3 94	8.20

Humus is also an important factor, especially in sandy soils, in assisting the capillary rise of subsoil water to the roots of crops. In a mixture of sand and humus, water will rise to the surface by capillarity much more rapidly than in pure sand. As is well known, soils which are properly manured and thus supplied with abundant humus retain more water and yield it up more slowly and evenly to growing crops than unmanured soils. The part which the humus takes in the water supply of crops is sufficient in itself for placing a high value upon the humus of the soil.

Humus and the Heat of Soil.

Humus soils are generally considered cold or sour, but this is not always true of them. In humus soils decomposition or oxidation of the organic materials is constantly taking place, and this oxidation is accompanied by the evolution of a certain amount of heat. A portion of this heat is used up in warming and evaporating the additional water stored up in the soil on account of the humus, but even after this is provided for there is still some heat left from the oxidation of the humus to aid in warming up the soil. It should be observed also that humus, as a rule, imparts a darker colour to the soil, and thus causes it to absorb more of the heat of the sun. In autumn humus soils are not affected by sudden changes of temperature to the same extent as soils poor in humus, the difference frequently being sufficient to ward off an early frost and to enable corn in the Northern States to reach its full maturity Applications of humus-forming materials, such as manure, have frequently been observed to raise the temperature nearly a degree, and this in colder climates is often sufficient to prevent the growth of a crop from being checked. In the colder regions soils which are poor in humus freeze much deeper than soils which are richer in humus. So far the attempt has been made to demonstrate that the chemical action of humus in rendering available plant food in the soil makes it of the greatest value as a fertiliser; that it consists in materially bringing about the physical conditions in the soil best suited to the growth of plants; that it furnishes a medium peculiarly [illegible] to the activities of such organisms as those of nitrification, which are useful in plant growth; and that loss of humus from the soil is always attended by a marked decline in its productiveness. It is now important to discuss the means by which this valuable constituent of soils may be conserved and increased.

Means of Maintaining the Humus of the Soil.

On account of the variable composition of humus it is difficult to state the definite amount which should be present in all soils. A large amount of humus, containing a very high per cent. of carbon, approaching in many cases the composition of charcoal, is not as valuable as a smaller amount of humus, which is capable of readily undergoing decomposition. With an excessive amount of water, and in the absence or scarcity of the proper soil elements, like lime, potash, &c., humus-forming materials may produce sour soils, but in good soils well stocked with lime, there is but little danger of this result. It is safe to conclude, therefore, that soils as a rule will be benefited by those systems of culture which conserve or increase the humus content. The liberal use of well-prepared farm manures, green manuring, and a judicious rotation of crops are the three most important means of maintaining the humus of the soil. In the arid regions, and in many of the prairie sections, the proper preparation of *farm manures* is a problem which has not as yet been satisfactorily solved. On account of the slowness of decomposition of the straw in the manure, many farmers in the regions named have begun to look upon manure as a detriment rather than a benefit to the land. In these regions, however, the soil is in greater need of humus that in the regions of uniform summer rains, and it is of the highest importance to devise some system of preparing the produced manure on the farm so that it may be utilised to the fullest extent. The humus materials of the soil may be increased by the use of well-prepared muck. It is best to draw the muck during the summer. After drying, it can be used as an absorbent in stables, for which purpose it is very valuable, many mucks having the power of absorbing more than their own weight of liquid. When muck is mixed with urine, it readily undergoes fermentation, which increases its fertilising value. The brown mucks are much quicker in their action than the black. A little marl or land plaster mixed with the muck keeps it from forming sour mold.

Clover and plants of the leguminous family are more suitable for *green manuring* purposes than any other class of farm crops, because, in addition to supplying an abundance of humus-forming materials, they add to the soil large amounts of nitrogen drawn principally from the air. In the South the cowpea is extensively used for this purpose with good results, and crimson clover has proved valuable on the sandy coast soils of the Eastern States. Where land is cheap and fertilisers and labour are expensive, green manuring will doubtless prove to be the most economical way of maintaining fertility. When land has a high value and labour is cheap, better returns will be obtained from feeding the crop to stock and using the manure rather than resorting to green manuring. Another means of maintaining the humus of the soil is the practice of proper systems of rotation of crops. The general laws which apply to the rotation of crops, are in perfect accord with the conservation of the soil humus, but definite rules cannot be given on account of the variations in soil and climate of different parts of the country. The methods of farming which are the most destructive to the soil humus are continuous grain cropping without manures, and the continuous cultivation of cotton, corn, or potatos, whilst the methods which increase the soil humus are the growing of grass crops and dairy and stock farming, which result in the production of large quantities of manure. These statements are by no means intended to discourage certain cultures, but to encourage a definite course of rotation in culture, and the use of more well-prepared farm manures, so as to keep up the humus of the soil.

Summary.

1. The decline in the crop-producing power of many soils is due to a loss of the partially decomposed animal and vegetable matters known as humus.

2. The humus of the soil is decreased by the continuous cultivation of grain, cotton, potatos, or any crop with which the land is kept constantly under the plough without the addition of any humus-forming materials.

3. The loss of humus involves a loss of the nitrogen, which is one of the elements composing humus. The loss of nitrogen from the soil is not always due simply to the nitrogen removed by the crop, but is frequently caused by waste of the humus by improper methods and systems of cultivation.

4. The humus of the soil is increased by the use of well-prepared farm manures, green manures, and by a systematic rotation of crops in which grasses, or preferably clover, form an important part.

5. The loss of humus from the soil results in decreasing its power of storing up and properly supplying crops with water. Soils with a liberal amount of humus are capable of more effectually withstanding drought than similar soils with less humus. In arid regions the loss of humus from the soil is more serious than in the regions of continuous summer rains.

6. In sandy soils the loss of humus is most severely felt. In poorly drained soils, where there is a deficiency of lime, potash, and other similar materials, the humus may form sour mould, but this can usually be corrected by a dressing of lime, marl, or wood ashes.

7. Humus-forming materials, like the decaying animal and vegetable matters in farm manures, have the power of combining with the potash and phosphoric acid of the soil to form humates which are readily assimilated by plants when acted upon by the proper soil organism. These humates thus increase to a marked extent the available plant food of the soil.

8. Farm manures and other humus-forming materials are not only valuable for the elements of fertility which they contain, but also for the power of making the inert material of the soil more available to plants.

9. In soils where there is a good stock of reserve materials it is cheaper to cultivate fertility through the agency of humus than it is to purchase it in the form of commercial fertilisers.

MILK PRESERVATION.

THE British Consul at Cherbourg devotes a long section of his last report to a new form of competition by French agriculturists with the British dairy industry. This is the growing export of milk from Normandy to this country. It appears that a wild herb which is very common in France proves an effective and harmless antiseptic, the discovery having been made by observing that the milk of cows which had eaten of the herb did not turn sour so rapidly as other milk. A single drop of a tincture obtained from the plant was found to stop all fermentation in a quart of milk for six days, while the butter made from milk so treated kept better than any other. The secret has been purchased by a French firm, which has fitted up a dairy and factory close to the docks at Cherbourg, and arrangements have been made to collect milk on all the roads leading out of the town. A detailed account of the working of the factory is given in the report, but certain disadvantages are pointed out. The tincture seems to disappear by evaporation after having sterilised the milk; at all events chemical analyses have failed to trace it. "What will be the effect of the prolonged consumption of this milk by children or invalids cannot yet be determined. The analysis is, of course, only negative, and medical opinion might not be favourable to the constant absorption of an unknown substance, however small the proportion." Further, there is no guarantee that the milk exported from Cherbourg has come from dairies where the inmates are free from infectious disease; it is certain that no diseased cow contributes to the supply, but there the guarantee ceases. Nor does the company's veterinary adviser inquire into the water supply of the farm. "It may be taken for granted, therefore, that the exported Cherbourg milk is safe only so far as the health of the cows producing it can affect it. It is the rich milk of healthy cows, at pasture all the year round, and milked in the open air." The early operations of the company during the closing months of last year were not as large as was anticipated, but over 76,000 gallons were despatched to England in October, November, and December last, and reached an average of 1,200 gallons a day during December. "If Normandy milk ever becomes a danger to our home dairy industry, it will be due to the intervention and assistance of British firms, doubtless greatly to the advantage of the British consumer, just as some years ago London firms went to the rescue of Normandy butter vendors when the Paris market was closed to them, an intervention so fruitful in consequences to the Norman farmer on account of the enormous extension thereby given to the Normandy butter export trade. Normandy, even more than Denmark, finds the butter export trade hampered by the competition of Australasia. No further expansion of the Normandy butter export trade is likely, but England will be deluged with foreign milk if Messrs. Lepont's attempt to form a limited liability company with the help of English dairymen is successful." The Consul points out that there are other preservatives besides this new secret antiseptic, and concludes :—"What is it then that stands in the way of West-country and Irish farmers doing by concerted action what Cherbourg proposes to accomplish with the assistance of British purveyors for the teeming millions of our metropolis? Surely some means might be found to remove that which blocks the way to a very effective means of relieving distressed agriculture."

MR. GEORGE A. BISHOP, steward to Sir Humphrey F. de Trafford, Bart., Hill Crest, Market Harborough, has been appointed by the Secretary of State for the Colonies to the position of superintendent of the Botanic Station, Bermuda—a position worth nearly £500 per annum. Mr. Bishop will be remembered as the originator and chairman of the Wolverhampton Chrysanthemum Society, and as an active member of the executive of the Wolverhampton Horticultural Club, and the Wolverhampton branch of the Gardeners' Royal Benevolent Institution. His brother, Mr. Alfred Bishop, head gardener at Westley Hall, Bury St. Edmunds, will succeed Mr. G. A. Bishop at Hill Crest.

"THERE'S A CHIEL AMONG YE TAKIN' NOTES, AN' FAITH HE'LL PRINT 'EM," has now become a saying so familiar that no apology need be made for introducing it; especially as it is intimately associated with the Press, which has helped in publishing the value of Holloway's Pills and Ointment. "The chiel that had been takin' notes" for the past fifty years of the cures effected by these wonderful remedies, has frequently informed the public that they have no equal. He has noted where they have been successful when other medicines failed, and he has been particular in stating that at this period of the year they are especially useful, as they cure or relieve dysentery, diarrhœa, all stomach and bowel disorders, bile, and indigestion.—[ADVT.]

ROYAL GARDENERS' ORPHAN FUND.

A VERY large and influential gathering was present at the annual festival dinner, held at the Whitehall Rooms, Hotel Métropole, on the evening of Wednesday, April 20. Charles E. Keyser, Esq., presided, and was supported by Sir Trevor Lawrence, Bart., Messrs. N. N. Sherwood, Martin J. Sutton, Leonard Sutton, J. Laing, H. B. May, H. Turner, G. Wythes, G. Gordon, S. Segar, R. Dean, A. H. Weeks, G. Reynolds, R. Cannell, W. Marshall, A. F. Barron, G. Monro, J. Smith, H. J. Jones, J. G. Veitch, G. Nicholson, Assbee, T. Rochford, P. Kay, and others. The dinner was served in the usual elegant and admirable style that characterises the functions held at this fashionable resort. At the conclusion of the repast the Chairman submitted the usual loyal toasts in felicitous terms, and these were well received, as is ever the case with a company of Britishers.

The toast of the evening, "Continued Prosperity to the Gardeners' Orphan Fund," was proposed by the Chairman, who said he felt the toast was rather a large order for him, and he felt diffident, especially coming after such noblemen and gentlemen who had previously filled the post of chairman at festival dinners. He knew, however, that the cause which brought them together was a first-rate one, and he was glad to announce that it had about £10,000 invested funds. The orphans under its care numbered nearly seventy, and in providing for these they were dealing with the children of those who had been connected with horticulture and had fallen by the way. The committee, he said, were sorry they could not afford more assistance, and he hoped he might persuade those present to unload their pockets for the sake of the orphan and the fatherless. He appealed to those who had been blessed with comfortable circumstances to aid the fund, as by so doing they were often helping in a very material manner the widow who also has been left unprovided for. The Chairman said he felt quite proud to preside over such a large attendance, and he felt sure that as so many had returned from Ghent to attend the dinner they had a very great and hearty interest in the charity, and would do all they could to make the contribution list of the evening a very large one. In conclusion, he eulogised the services of their treasurer, N. N. Sherwood, Esq., who for so long had held his present position and done so much for the fund. With the toast he coupled the name of Mr. Sherwood. The toast was drunk with enthusiasm and followed by rounds of cheering. In response, Mr. Sherwood returned thanks for his hearty reception, and thanked the chairman in a most hearty manner for his presence at their annual dinner. He then briefly referred to the position of the fund, its usefulness, and its need. He reminded the meeting that last year the subscriptions fell off a little, and that regular annual subscriptions were greatly needed, so that an assured income might be obtained. He hoped to see the time when all the orphans who were needy would be put on the fund as each annual election-day came round. He also suggested that gardeners should bring the matter before their employers, and as one way of helping the fund, suggested that owners of large horticultural establishments should contribute thirteen guineas per year, and so maintain one orphan, and this subscription might be on the name of the mansion, a favourite child, or otherwise be a memorial. He always did all he could for the society, and it was a great pleasure and recompense to read some of the thankful letters received from widows who had children on the fund. Such letters went to his heart, and would do to those of others could they but read them. Such letters showed what a grand institution they were assisting. Mr. Sherwood's brief but able speech was well received by the company.

The next item was the reading of the subscription list, and as various familiar names and the amounts promised were made known, the applause grew louder and the company very enthusiastic. The following is the list as read: Mr. C. E. Keyser, £116 16s.; Mr. Assbee, £63 6s.; Mr. N. N. Sherwood, £58 14s.; Mr. G. Reynolds, £32 18s.; Mr. N. M. Rothschild, £26 5s.; Mr. M. J. Sutton, £25; Mr. L. Sutton, £25; Mr. A. de Rothschild, £10 10s.; Mr. S. M. Segar, £19 19s.; Mr. A. W. Weeks, £16 5s.; Mr. J. McLeod, £10 16s. 6d.; Mr. W. Robinson, £10 10s.; Mr. A. W. Sutton, £5; Mr. H. J. Adams, £5 5s.; Mr. J. B. Stevenson, £6; Messrs. Dicksons, Chester, £5. These, with further smaller amounts, made up a grand total of a little more than £515.

The toast of "Gardeners and Gardening" was proposed by Mr. Martin J. Sutton, who said he came to fill the place that should have been occupied by his brother, Mr. A. W. Sutton, who had been detained by the illness of one of his children. He observed that he was not a gardener, and that, strange as it might seem, he had no garden; he was an agriculturist, and as such he could not but admire the intelligence and spirit of gardeners as a body. He felt perfectly sure that one of the methods by which agricultural prosperity might be restored was that the farmer should become a great deal more of the gardener. He referred to the remarkable advance made in horticulture, and concluded by expressing the opinion that gardeners were a splendid set of men. Mr. A. H. Weeks responded, and thanked Mr. Sutton for his eulogistic remarks anent the horticultural profession and horticulturists. The latter were always among the most trusted of servants, and they often took far more care of their employer's property than of their own. One had only to become acquainted with horticulturists to fully appreciate them.

Mr. W. Marshall, the chairman of the Executive Committee, ably proposed "The Health of the Chairman," stating that whatever other claim he had upon their notice, Mr. Keyser claimed their attention for the admirable way he had presided, and the handsome manner in which he had helped the fund financially. He was glad to say that the fund was now becoming widely known and British gardeners were understanding that it had been instituted and was being kept going purely for their sakes and that of the children of any who fell in the battle of life. C. Keyser, Esq., responded suitably, saying that he felt he took as great an interest in horticulture as any of the noblemen who had filled the chair in earlier years. He alluded to his able gardeners—Mr. Gleeson at Stanmore and Mr. A. Galt at Aldermaston Court—and said that he hoped in future to afford them ample opportunity of displaying their ability at forthcoming London and provincial shows, for he saw how well the tradesmen exhibited, and as an amateur he felt he ought to show what his establishments could produce of fruits, flowers, and vegetables. He modestly alluded to his share of the subscription list, and said that he expected further sums from friends abroad, and hoped before long to have a further accession of £50 or so. As an amateur he was proud to be found among so many well-known operative gardeners, and he thanked them all for their generous response to the fund and to the toast of his health.

The toast of "The Press" was proposed by Mr. R. Dean, who alluded briefly to the value of the daily press, and more fully to the great indebtedness of the fund to the horticultural press, coupling with the toast the name of Mr. G. Gordon, editor of the GARDENERS' MAGAZINE.

Mr. Gordon responded, thanking the company for their hearty response to the toast. All horticultural pressmen felt it their pleasure and duty to do all they could for the gardening charities. He considered that the speedy rise of the Orphan Fund was largely due to the influence of the horticultural press and that of its representatives who assisted in the conduct of the charity. As compared with the sister charity, they had made as much progress in ten years as it did during the first thirty years of its existence. With regard to an increase of subscriptions and contributions, he held that very much might be done by gardening associations and horticultural societies throughout the kingdom, as with a little enterprise concerts, exhibitions, &c., might be instituted for the benefit of the fund. From this source alone he thought that not less than £500 a year ought to be received.

The function concluded shortly after ten o'clock, and was altogether a most enjoyable one. The tables were prettily decorated with daffodils, azaleas, orchids, &c., contributed by Messrs. Barr and Son, Sander and Co., J. Laing and Sons, and others. Messrs. Wills and Segar arranged the flowers. Votes of thanks were accorded all the foregoing firms. The musical arrangements of the evening were in the hands of Mr. Herbert Schartau, who, as usual, provided an admirable entertainment.

LANDSCAPE GARDENING.

Design.

IN his fifth lecture Mr. Milner stated that few definite rules can be insisted on with regard to design, but a few general principles may be laid down. Sites, soils, and environment largely dominate our landscapes. In fact some one has truly said that gardens should grow out of rather than be imposed upon their surroundings. Simply to copy another place or design is to invite failure. Geological formation, surface features, extent, climate, aspect, near and distant properties and prospects, powerfully affect our gardens. In the pictures created by landscape gardening the view is always changing—we see the picture on all sides; colours change and plants grow, so that in a few years a mere complementary effect may have changed to a tall tree and may be wholly marring the original effect in the landscape. In forming the surface of the ground into lines of grace and beauty we can hardly do better than follow pretty closely on the heels and example of Nature. In Nature, as already observed, straight lines are seldom found. Straight lines are the production of art, so the terrace, being artificial, may be treated more formally. Beyond the line of the terrace wall, slope or walk, the design of the garden may be naturally treated and freedom allowed to assist. Uneven ground, curved lines, and planting, are the chief means employed to bridge the barrier between the formal and the natural. Groups should not only be, but always appear to be posted in the right place. By the use of different heights of trees and shrubs great variety is obtained. Keep the prominent points high and the intervening bays low; avoid monotony and uniformity. Special subjects of interest such as roseries, rivulets, rockeries, groups of shrubs, and herbaceous plants increase the freshness, variety and beauty of landscapes.

Lawns express repose, and should be more than a grassy expanse shut in between woods—they should lose themselves as natural openings or glassy glades in a wood. Nothing should, however, block up or decrease the expression of expanse and repose, nor must it be forgotten in respect to distant prospects that the eye involuntarily travels down hollows; that trees and shrubs form the richest fringe to lawns, and that the rise and fall from one level to another on lawns should not be made by one railway-like embankment drop, but by means of the ogee or double curve. Neither should the extent of the whole garden or lawn ever be visible at a glance. The unfolding as well as the growth should be gradual—there should also be a difference between the furnishing of the gardens proper and park.—Exotic, more rare, and smaller trees should prevail in the gardens, while in the park big single trees or plantations should appear. In the garden we group the plants in regard to form, colour, size. We plant the hills and bare the vales, but this only expresses half a truth—for Nature plants on every side, not alone on the hills. The great point is to shun uniformity or monotony of size, form, and colour.

Terrace and Flower Gardens.

Coming nearer to the mansion, and with a general reference to a house of the nineteenth century, Mr. Milner proceeded to give much information as to the formation of parterres and terraces as features of garden landscape. He stated as an axiom that the treatment of the ground next the house should be artistically formal, with regular lines of turf, slopes, walks, or beds, all displaying harmony, so far as may be, with the architectural character of the building. As already shown the foundation of this is laid in gravel or other walks of sufficient width, with stretches of grass on either side, turf banks and steps leading from higher to lower levels, and frequently, if sufficient space on the level of the terrace allows it, a formal flower garden, either on the same level as the house, or sunk in a panel a foot to a yard below it. Much information was given as to the size and character of terrace gardens. Their general characteristics should be greater length than width. Such gardens may be laid out on grass or gravel, and edged with box, yew, or other dwarf shrubs. In furnishing these terrace gardens it should be borne in mind that they are chiefly looked down upon from a height of some five feet, and consequently they should not be placed too near to the house. Besides the usual bedding and foliage plants, choice variegated and other shrubs, trees and plants, such as box, yew, retinosporas, hollies, euonymus, and yuccas, have a good effect. As gardens posted so near to the house are always in sight no pains should be spared to preserve them always in full freshness and beauty. Much attention to details will be necessary, as height must be regulated by pruning, and the plants should be frequently renewed during the season, and so far as possible they should be kept in bloom through most of the season. Sunk panel gardens look best when about eighteen inches deep, and most beds embellishing terrace gardens, whether in the form of ellipses or rectangular, should run lengthways and in line with the [illegible].

Mr. Milner, showing some drawings and sketches, referred to the [illegible] effects of avenues running through a wood in the direction of a [illegible] distance. A grand avenue should have a width of fifty feet between the trees and at least forty from tree to tree, the best trees being elm, ash, oak, horse chestnut, and lime. Madresfield Court was cited as a domain where a good [illegible] fine avenue could be seen. Much useful information as regards estimating [illegible] then followed.

With some remarks on the laying out of public parks and cemeteries, proposals for the improvement of villa residences, and the presenting to each student of a rough sketch to be enlarged and improved before the examination, Mr. Milner concluded a series of lectures that have excited much interest and suggested much thought on a branch of our science and art that is far too generally neglected in these days of hurry and rush.

Professor Bayley Balfour at the close conveyed the hearty thanks of the meeting to Mr Milner for the grasp of subject and ability that he had displayed, and the amount of information he had given them. He hoped also Mr. Milner might be prevailed upon to publish the lectures *in extenso*. The lectures were free and open to the general public, ladies as well as gentlemen being welcome.

D. T. [illegible]

CYCLAMEN AT GODINTON PARK.

We are constantly in the habit of seeing at the Drill Hall during the winter months large collections of cyclamen in splendid order, but these are contributed by nurserymen, and it is rarely that we see them grown to any extent in private gardens (at least, that is my experience); we see some plants, it is true, more or less well done, but it is rare to find a house entirely devoted to them, and therefore a notice of a collection I saw a short time since may not be uninteresting to your readers.

Godinton Park, once the family residence of the Tokes, and now that of Mr. G. Ashley-Dodd, is situated about a couple of miles from the well-known railway station at Ashford, in Kent. The park is not very extensive, but contains some fine timber, while the Chestnut Toll is a landmark for many miles round. With this exception, however, the park is level, differing in this respect very much from Eastwell and Chilham, which are situated on the range of hills that run through this part of the county; but of the house itself it is impossible to speak too highly; it is not large, although it has been added to considerably in the last two years. It is a delightful specimen of Tudor work, and the hall and staircase are beautiful examples of the best period of that exquisite style of architecture. I do not think that any lover of the beautiful would grudge the time, if he only stopped at Ashford and drove out to see this charming house. The additions made to it were under the supervision of Mr. Blomfield, and they do not in any way interfere with its character. I have known Godinton all my life; I have seen during tue past thirty years many occupants, but being hitherto only tenants they had not any special interest in the place, consequently an air of neglect brooded over park and gardens; when it was purchased by Mr. G. Ashley-Dodd all this was over; the whole aspect of the place was changed; this has been especially the case in the gardens, which are quite altered. A rose garden has been made, and the most popular flowers are cultivated, and under the able care of Mr. Frost (son of that Mr. Frost whom many of us remember at the Royal Nurseries, Slough) promised to be a very attractive feature in the neighbourhood.

The end of March is not generally an interesting time in which to visit a garden, and I was greatly impressed with the rich treat offered through Mr. Frost's intelligent care of his plants; and to one who, like myself, can look back to the time when the Persian cyclamen was considered one of the most difficult plants to grow, the change is marvellous indeed; the rapidity with which plants are grown to a flowering size, from the time of sowing, is very remarkable; there were plants here the seed of which was sown in December, 1896, that had been in bloom for some considerable time; the corms were of good size, and carried about a couple of dozen flowers; this, however, can be exceeded if necessary, and I believe Mr. Frost could have them in flower in eight or nine months if required; I saw some sturdy little plants in the vinery, raised from seed sown in December, that will come into flower in November next. There was the usual variety of colouring, ranging from the purest white to the darkest crimson, and it must be remembered that all these results have been obtained by a process of selection, and not of cross hybridisation, that is, no other species have been introduced to induce these variations; some of the flowers, those of the giganteum strain, as it is called, are very large, and the plants two years old were bearing hundreds of blossoms. The different varieties can be relied on to come true from seed, although showing some variations in the tints. There is also some difference in the form of the flowers; some are more open than others; for instance, "Butterfly," which is a perfectly pure white, is much more open—that is, does not turn its petals back so much as the old varieties do; and there are some which have an ugly fashion of turning four of their petals, while the other does not reflex at all; this does not at all add to their beauty, and I myself should be inclined to discard these, and retain only those of a more regular form. Some curious things for which we cannot account come out in course of cultivation; thus the very dark variety known by the name of Vulcan does not produce seed anything like so freely as the others, nor are the flowers so large; why this comparative sterility will occur in this dark-flower variety it would be difficult to say. Then, again, in the matter of perfume, how does it happen that some have that delicate scent that is associated with its name, Cyclamen persicum odoratum, while in a great majority of plants it is totally wanting? As you enter the house in which Mr. Frost has his plants staged you at once recognise this delicious scent, but you may take up plant after plant and be unable to detect it, some only possessing it. And so in the matter of foliage; in some plants the leaves are beautifully marbled, and in others nearly plain; in some, as in the giganteum strain, the foliage is very large; in others it is neat and compact.

How, then, are these admirable results obtained? In the first place a good strain of seed is obtained and this is sown in November or December, and placed in an intermediate house, the compost used being light and friable; as soon a the corms are of a sufficient size (which will be about the size of a large-sized pea), they are pricked off into thumb-pots, the compost used being loam, leaf-mould, well-rotted manure, and sand, and as the plants increase they are again potted into larger pots in the same compost. A cool frame is the best place for them during the summer months, and a northerly aspect the best position for the frames, air being given at all times, and the plants not being exposed to rain; it will thus be seen that the cultivation which these plants receive is based on good sound principles; there is no quackery about it, and there is nothing that any amateur may not carry out. Of course the same method of treatment may be adopted where an amateur has smaller facilities, and wishes to grow a smaller number of plants. The curiously-crested form which Messrs. Low and Co. have exhibited at the Drill Hall and elsewhere does not appear to have occurred in the collection under Mr. Frost's care, but there does not seem to be any end to the variations which we may expect in this beautiful class of plants. Should growers be able to obtain large white varieties with a coloured crest in the centre of each petal it will form a very pleasing addition to those already in cultivation, and, [illegible] what has already taken place within the last twenty-five years, you may well say "Why not?" At any rate, if they will mark any deviation from the normal form, it is most likely they will obtain something which will be worth looking after.

H. H. D'.

HORTICULTURAL CLUB.

The usual monthly dinner and conversazione took place on Tuesday evening, April 12; notwithstanding the holidays and the Ghent Exhibition, which drew several of the members, there was a good attendance. The chair was occupied by Mr. George Paul, J.P., V.M.H. The Rev. George Engleheart was the [illegible] of the evening, and gave a very valuable address on "Seedling Narcissi," in raising which, as is well known, he has been so successful; he exhibited some of his [illegible] productions, which were greatly admired, and had previously obtained [illegible] and awards of merit at the Drill Hall; an interesting discussion followed, in which many of those present joined.

ANSWERS TO CORRESPONDENTS

Editorial communications should be addressed to the Editor of the Gardeners' Magazine, 148 and 149, Aldersgate Street, E.C.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, &c., for reproduction in the Gardeners' Magazine. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

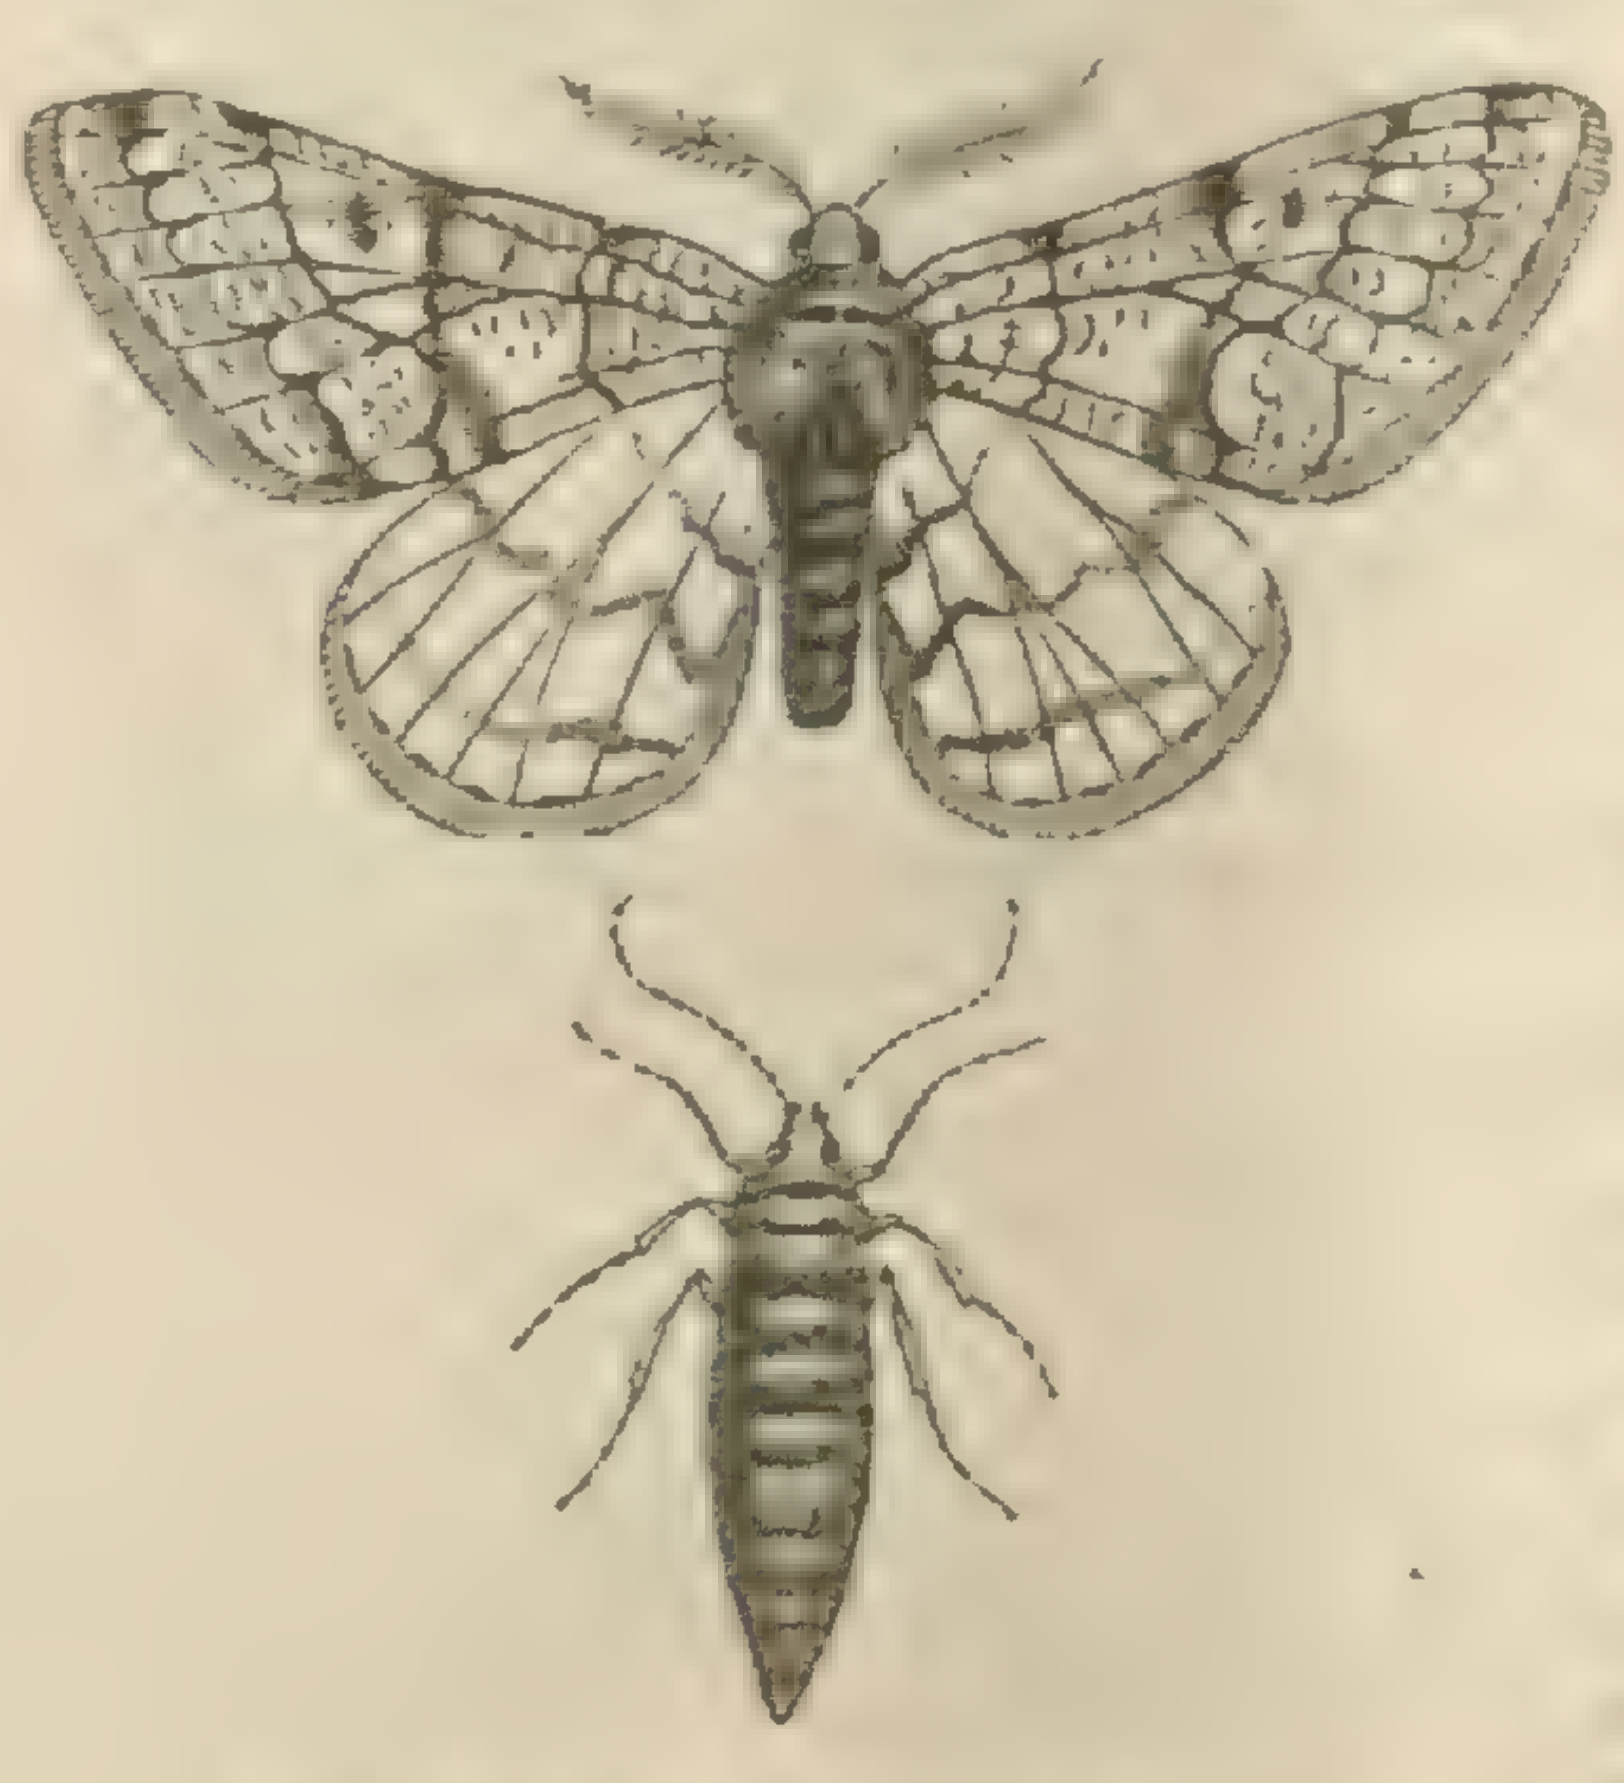
Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the Gardeners' Magazine, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

Secretaries of horticultural societies are invited to send early notification of forth coming exhibitions and meetings, and are requested to advise us concerning change of dates

Florists' Directory.—S. H., Reading: The book to which you refer is "Maddock's Florists' Directory," a work published in 1792, by James Maddock, a Walworth florist of no small repute. Its full title reads, "The Florists' Directory; or a Treatise on the Culture of Flowers"; to which is added a supplementary dissertation on soils, manures, &c. The flowers treated upon in the 272 pages are the hyacinth, tulip, ranunculus, anemone, auricula, carnation, pink, and polyanthus. Copies may sometimes be purchased at second-hand book-sellers, and they vary in price according to their condition.

Planting Pansies.—G. E. A., Rugby: It is not too late to plant pansies, but the sooner the work is done the better, so that the plants become established before dry weather sets in. A deep moist and rich loam suits pansies, as it will keep them cool. Give water as necessary after planting, and early next month give the bed or plot a top-dressing or mulch of equal parts leafsoil and dried cow manure, sifted and mixed together; put this on directly after a good shower or heavy watering. Allow no flower buds to develop until you are sure the plants are well established. Keep the surface regularly and frequently stirred with a Dutch hoe and give an occasional overhead spraying with clear water as the sun begins to decline until flowering commences.

Pale Brindled Beauty Moth.—L. D., Gloucester: The twigs sent have clusters or rings of caterpillar eggs upon them, doubtless those of the pale brindled beauty moth *(Phigalia pilosaria)*. This moth appears early in the spring, sometimes by the middle of March, and the female soon commences to lay its eggs on small shoots towards the top of the tree, and form a ring round it. As soon as the season is sufficiently advanced for the leaves to unfold, the caterpillars are hatched, and at once commence their attack upon the delicate foliage. They are about an inch in length, pale green, with tufts of hair at the joints. The ants have a decided partiality for the caterpillars, which are carried away by them in large numbers when first hatched, more particularly from trees not exceeding eight or nine feet high. The male moth, shown in the upper part of the illustration, is of comparatively large size, the fore wings greenish grey, with brown markings; the hind wings are dull white, with bright brown heavy cross stripes. The female is wingless, small, and of a coffee-brown colour. The attack of the caterpillars of this moth may be greatly mitigated, if not prevented, by the use of grease bands, as in the case of the winter moth. This band is formed by spreading cart grease of good quality over a broad strip of grease-proof paper, and then fastening it round the stem of the tree. Spraying the trees with a solution of Paris green in the proportion of two ounces to forty gallons of water, when the caterpillars are hatched, will destroy large numbers by poisoning their good. Repeat the spraying after an interval of a fortnight, and if found desirable spray the mature foliage with a solution of half a pound of Paris green to a hundred fallons of water. Always keep the mixture agitated when spraying.



Pale Brindled Beauty Moth.
Male and Female.

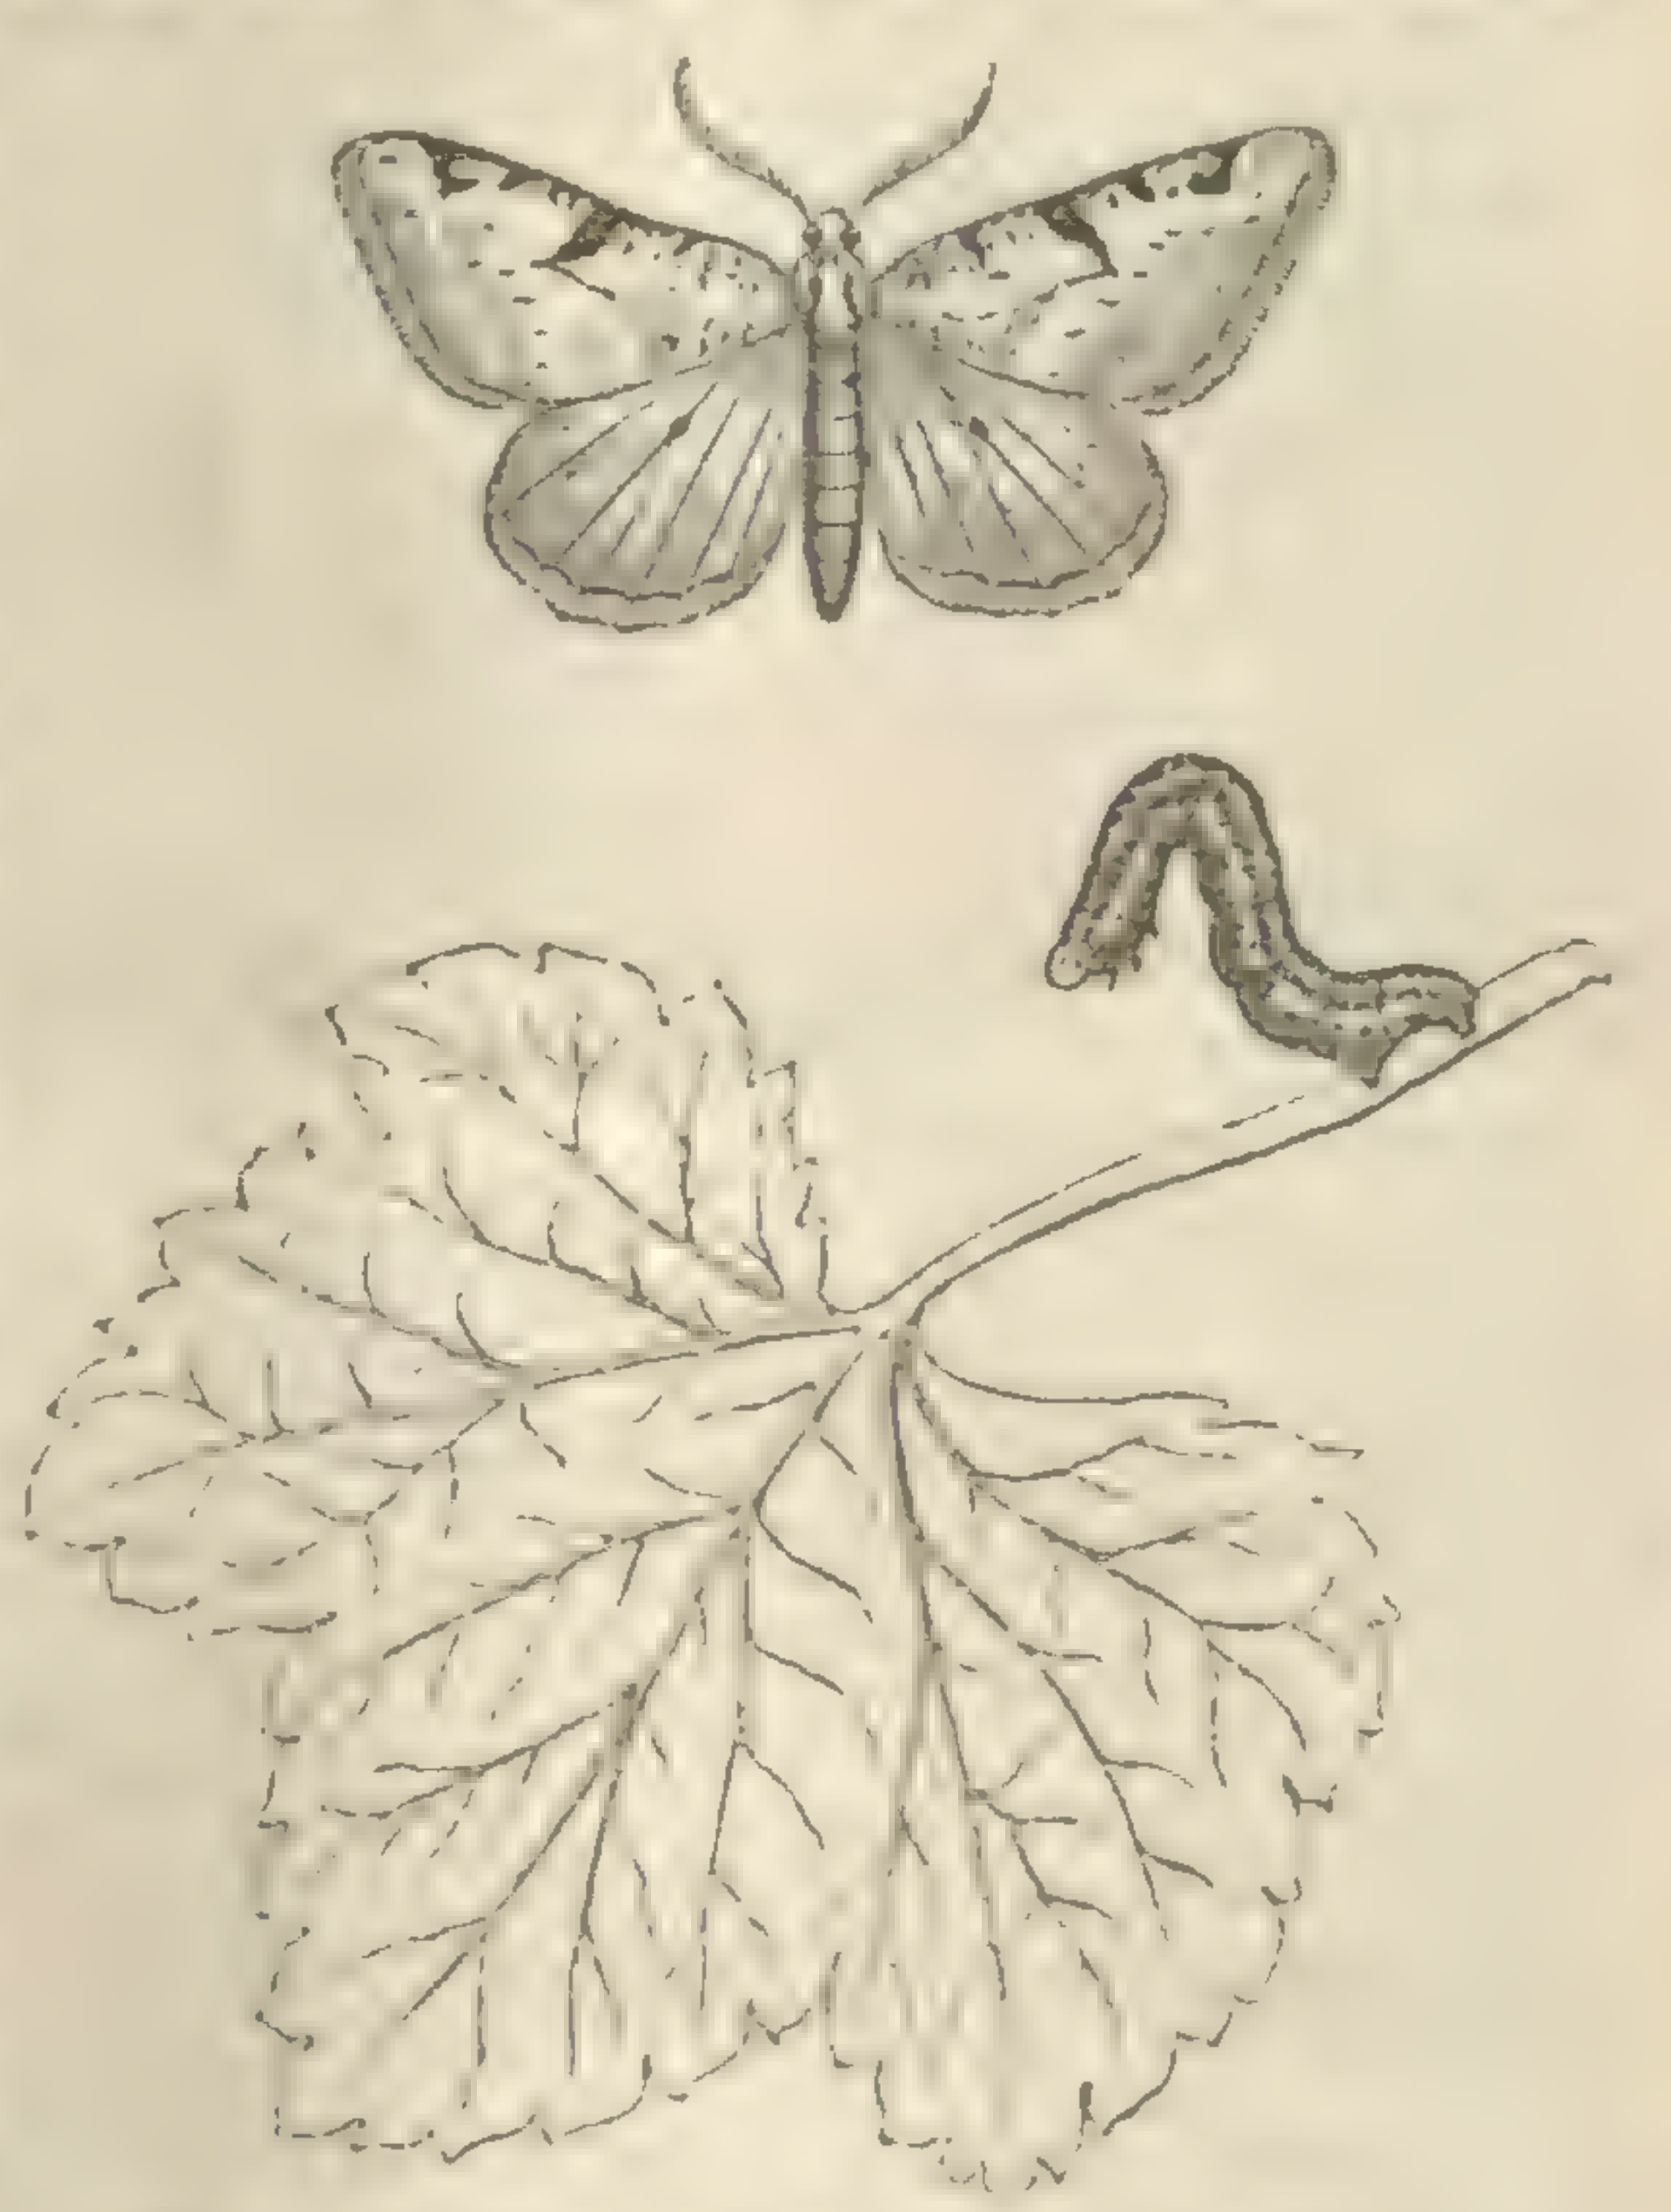
Window Boxes.—W. E. C., Kensington: It is by no means difficult to have a really good window box display at this season of the year, provided a little care be taken with the plants, such as providing them with water when necessary, for the soil in window boxes needs to be watered several times during an ordinary winter. We have, at the present time, a really good show of hyacinths, tulips, and daffodils, with a background of blood-red, yellow, and an intermediate form of wall flowers, and a front margin of fancy and gold-laced polyanthuses. Medium-sized clumps of doronicums are placed in the more roomy parts of the box, and these will have expanded their earliest golden flowers ere this reply appears in print. In the same boxes we had an early display of snowdrops, chionodoxas, and crocuses of sorts. Substantial soil in the first instance, and water as needed are, of course, essentials for an early spring show.

Throatwort.—H. H., Bury St. Edmunds: The scientific name of the throatwort is Trachelium cæruleum; we agree with you that it is a plant not often seen, but still very desirable. It is a native of Spain and Italy, and has been in cultivation for about 350 years. For greenhouse and conservatory decoration and for grouping it is a charming plant, but for some unknown reason it has been banished from most gardens during the past half-century, until now, quite a large number of our principal gardeners do not recognise it when they see it. It is easily propagated from seed, or by cuttings made from the side growths taken and inserted in sandy soil during the present month. A little warmth assists root formation, but as soon as the cutting becomes an individual plant it must be grown hardily, a cool greenhouse or frame sufficing. Pot on as necessary, thirty two-sized pots being large enough for general use. Give liquid cow manure as soon as the flower heads are seen. There is a white-flowered form of the species.

Hardy Ferns.—M. S., Basingstoke: It is now quite safe to remove dead fronds from hardy ferns, and also all the brown and decaying fronds from those species which do not lose all their frondage during winter—such as the harts-tongues. Plants may be divided now, though we prefer to wait until growth is a little more advanced, provided the situation of the fernery is considerably shaded. Where the soil has been washed away from the fern stocks add some new material, such as good loam and leaf mould in equal quantities; peat may be added but is not a necessity.

Bouillie Bordelaise.—F. H., Cambridge: As this is the best fungicide for such pests as potato and tomato diseases, apple scab, &c., we have not the least objection to repeating the formula and method of manufacture for the benefit of a new reader. There are several methods of making Bouillie Bordelaise or Bordeaux mixture, but one of the simplest and most effective compositions is as follows: mix four pounds of quicklime in a gallon or so of water and allow this to settle; in another vessel mix six pounds of sulphate of copper in four gallons of water, and to this add the liquid from the lime solution; mix the two liquids thoroughly, and add sufficient water to make forty gallons of the mixture; before application, give the mixture another good mixing and apply it in the form of a very fine spray that will settle on all parts of the trees or plants under treatment.

The Small Magpie Moth.—C. A., Uxbridge: The slim caterpillars sent are examples of the caterpillar of the small magpie moth (*Phalæna halias*). Sometimes this proves as great a pest as the Magpie Moth (*Abraxus grossulariata*), and we have already seen specimens on red-currant bushes ready to feed upon the tender foliage. Hand-picking will be the best method of getting rid of the pest, and a sharp-eyed lad can soon detect and destroy the caterpillars as they lie close to the stem. Dust soot and lime upon and under the bushes. At the end of May the caterpillars that have escaped will be full fed, when they will descend to the ground and among the surface nodules they will assume the chrysalis state. This is the gardener's opportunity, for if the surface soil is removed to the depth of an inch and a half and burned or buried deeply (about two feet) in some other part of the garden, the pest will be got rid of effectually. Replace the soil with some good material such as road-scrapings, old potting-bench refuse, or rich garden soil.



Small Magpie Moth, and Caterpillar.

Nitrogenous Manures—R. B., Kent: The question you raise with reference to the rapidity with which nitrate of soda and sulphate of ammonia becomes exhausted, is of considerable interest. As Sir J. B. Lawes has pointed out in discussing the valuation of unexhausted manures: When nitrate of soda is used as manure, its nitrogen does not enter into fixed combinations within the soil, but nitrate is dissolved in the soil-water, and unless taken up by vegetation, much passes into the drains, or into the subsoil beyond the reach of the roots of the crops. When salts of ammonia are used, part of the ammonia is temporarily taken up by the soil, but it is, more or less rapidly (according to the character of the soil and of the season), converted into nitrate, and is then subject to loss by drainage as when nitrate of soda is used. The loss by drainage will, as a rule, be the most when these manures are applied to grain crops, but materially less when applied to root crops or to permanent grass, as these crops have a more extended period of growth, tending to keep the soil-water nearer the surface, and to greater utilisation of the nitrogen. When these artificial nitrogenous manures are used for grain grops, they leave some nitrogenous crop-residue (stubble and roots); the more so the greater the amount of the increased produce due to the manure. When used for root crops, there will, as a rule, be much more of the supplied nitrogen recovered in the crop than in the total produce of a grain crop. When applied to permanent grass, there will also be much more of the supplied nitrogen recovered in the increase of crop than when applied to a grain crop; and there will at the same time be more crop-residue in the case of permanent grass.

The Pear Midge.—H. P., Norwich: Little can be done to combat the pear midge (*Diplosis pyrivora*) after the flowers expand as the pest makes its way to the centre of the flower a little previous to the buds opening. If your pears have not yet opened their flowers spray them frequently, until expansion, with the following mixture: Seven pounds of soft soap and ten pounds of quassia chips, boiled together with a little water; add a little Paris green, strain through a cloth and then dilute with one hundred gallons of water. Use the mixture warm. Pick off all infested fruits as they appear and burn them; they can be detected by their abnormal swelling. In his description of the species, Schmidberger states that the number of eggs these midges lay vary from one to sixty, which hatch in a very short time, if warm at four days from deposition; before the blossom is expanded they descend to the core; here they continue till the inside is exhausted. They generally leave at a rainy time, coming out on to the exterior of the young fruits, by cracks or boring out, from whence they spring to the ground. Often they remain in the pear until the fruit falls. The period of the full development of the insect commences as early as January 9, and continues consecutively until April 18, or even later. A gall midge has been seen with its long ovipositor inserted on the side of the blossom before it opened, but generally it lays its eggs on the middle of a single blossom by piercing the petals. The adult insect's general colour is dark grey or black; average length, two-fifths millimetre (or about one-twelfth of an inch): ovipositor, when extended, longer than the rest of the body; pupa, average length, three millimetres; head, thorax, legs, and wing-cases blackish; abdomen, yellow; larvæ length four millimetres; colour, pale yellow; surfaces polished, and very faintly reticulated.

ENGAGEMENTS FOR THE ENSUING WEEK.

MEETINGS.

Tuesday, April 26.—Royal Horticultural Society; Committees meet at Twelve o'clock. Lecture at Three p.m. on "Fragrant Flowers v. Scented Leaves," by Mr. F. W. Burbidge, F.L.S.

The National Auricula and Primula Society will hold its annual exhibition at the Drill Hall in connexion with the R.H.S.

AUCTION.

Monday, May 2.—[illegible] Plants, [illegible] Lane, Clapton.

OBITUARY.

Mons. Aime Girard, who died a few days ago, was a great benefactor to his native country, for few men have done more than he to popularise scientific agriculture in France. His chief researches were in connection with the improvement of sugar beet and potato cultivation. He will be long remembered; his experiments in potato improvement and cultivation gave wonderful results, for he showed how the crop could be made to yield a third more than previously, that the percentage of starch could be raised considerably, and that for stock feeding the tubers could be rendered more valuable than before. Aime Girard was the first to conduct experiments in the prevention of potato disease on a proper basis with Bouillie Bordelaise, a mixture now so popular as a fungicide, and discovered by him in use in some outlying French vineyards. The French nation has lost a great man, and agriculturists a friend, by the death of M. Girard in his sixty-eighth year. He was an untiring worker, and his best monument will be the good work he accomplished, and it will keep his name before generations to come.

Mr. W. H. Cullingford, who has long been a warm supporter of associations having for their object the encouragement of floriculture, died, we regret to announce, at his residence at Tunbridge Wells a few days since, in his sixty-eighth year.

Mr. James Crute who, in conjunction with Mr. William Marshall and the late Shirley Hibberd, founded the United Horticultural Provident and Benefit Society, died, we regret to record, on the 14th inst. Mr. Crute was an ardent amateur horticulturist, and devoted much attention to the improvement of garden pots, but of late years he has, in consequence of advancing years, been living in retirement at Bognor.

MARKETS.

Covent Garden.

The general demand is brisk, and with fairly good supplies prices are maintained. For new vegetables there is an increasing request, and these realise high rates. Flowers are plentiful, and sell freely at moderate prices.

Fruit.—Nova Scotian apples, 15s. to 25s. per barrel; Tasmanian, 12s. to 16s. per case; pineapples, 2s. to 5s. 6s. each; bananas, 5s. to 10s. per bunch; lemons, 6s. to 15s. per case; English grapes, 3s. to 5s.; Belgian, 2s. 6d. to 3s. 6d. per lb.; Valencia oranges, 9s. to 15s. per case; Jaffa, 10s. to 12s. per box.

Flowers.—Arums, 3s. to 4s.; carnations, 1s. to 3s.; eucharis, 4s. to 5s.; gardenias, 2s. to 3s.; Lilium Harrisi, 4s. to 6s.; tea roses, 6d. to 1s.; pink roses, 4s. to 8s.; red roses, 3s. to 6s.; cattleyas, 6s. to 9s.; Odontoglossum crispum, 1s. 6d. to 4s.; tulips, 6d. to 1s.; and tuberoses, 1s. to 1s. 6d. per dozen blooms; Adiantum cuneatum, 4s. to 8s.; marguerites, 2s. to 4s.; narciss, various, 1s. 6d. to 4s.; Roman hyacinths, 4s. to 6s.; daffodils, 2s. to 6s.; mignonette, 2s. to 4s.; pelargoniums (scarlet), 4s. to 9s.; wallflowers, 4s. to 6s.; primroses, 9d. to 1s.; and violets, 9d. to 3s. 6d. per dozen bunches; azaleas, 6d. to 1s.; stephanotis, 4s. to 6s.; lily of the valley, 6d. to 1s. 6d.; and pelargoniums, 6d. to 1s. per dozen sprays; bouvardias, 6d. to 8d.; white lilac, 3s. to 6s. per bunch.

Vegetables.—English tomatos, 9d. to 1s. per lb.; Canary, 1s. to 1s. 9d. per tray, 3s. 6d. to 4s. 6d. per case; mushrooms, 6s. to 8s.; eschallots, 2s. per 12 lb.; French asparagus, 2s. to 5s.; Italian, 1s. 4d. to 1s. 9d. per bundle; spinach, 2s. to 2s. 6d. per bushel; Forced rhubarb, 1s. to 1s. 6d.; natural, 2s. 6d. to 3s 6d. per dozen bundles; mint 5s. to 6s. per dozen bunches; endive, 1s. 8d. to 2s. 6d.; lettuce, 9d. to 1s. 3d.; cos, 2s. to 2s. 6d.; cucumbers, 2s. 6d. to 5s. 6d.; cauliflowers, 1s. 6d. to 2s. 6d. per dozen; Egyptian onions, 6s. 6d. to 7s, 6d. per cwt.; English spring, 2s. 6d. to 3s. 6d. per dozen bunches; green peas, 4d. to 5d. per packet; French beans 3s. to 3s. 6d. per basket; Canary new potatos, 10s. to 15s.; French, 2d. to 2½d. per lb.

Borough Potato Market.

Warmer weather has caused a decline in the demand for potatos, so with moderate supplies prices are only just maintained.

Dunbars, 120s. to 130s.; Scotch Magnums, 105s. to 115s.; Hebrons, 100s. to 110s.; Snowdrops, 85s. to 100s.; Bruce Maincrop, Sutton's Regents, Reading Giants, and Saxons, 95s. per ton; Belgians 4s. to 4s. 3d. per bag. New—Maltese rounds, 12s. per cwt.; Jersey hothouse, 3½d. to 4d. per lb.

THE WEATHER DURING THE WEEK ENDING APRIL 16, 1898.

The mean reading of the Barometer during the week at Greenwich was 29·66 inches, and that of the Thermometer 49°·3, the latter being 3°·1 above the week's average in the 50 years 1841—90. The direction of the wind was variable, the horizontal movement of the air being 32 per cent. above the week's average in the 16 years 1860—75. The duration of registered bright sunshine in the week was 25·8 hours. The measured rainfall amounted to 0·31 of an inch.

EPPS'S COCOAINE.

COCOA-NIB EXTRACT.

The choicest roasted nibs (broken-up beans) of the natural Cocoa on being subjected to powerful hydraulic pressure, give forth their excess of oil, leaving for use a finely-flavoured powder —"Cocoaine," a product which, when prepared with boiling water, has the consistence of tea, of which it is now, with many, beneficially taking the place. Its active principle being a gentle nerve stimulant, supplies the needed energy without unduly exciting the system. Sold only in labelled Tins. If unable to obtain it of your tradesman, a tin will be sent post free for 9 stamps.

JAMES EPPS AND CO., LTD.,
Homœopathic Chemists, London.

WEST'S
PATENT
IVORINE
PLANT LABELS
NAME TO BE WRITTEN ON WITH ORDINARY LEAD PENCIL OR PEN AND INK.

The "Ivorine" Writing Disc, Being made of a specially prepared substance, having the properties of real ivory, is imperishable, and does not corrode or eat away, like wood and metal labels; and being ivory-white, when written upon it shows to perfection. And also, as the writing is on the Ivorine itself it is permanent, though washable, and does not become unreadable, as is the case with all painted labels, as the paint gets old. It is for all purposes, and will last a century, either in a greenhouse or out in a garden, and not only is it always ready for use, and may be written on both sides, but the name when written in pencil may be easily rubbed off, and so used as many times as desired.

Samples and Lists of the West's Patent Specialities post free. Price, **9d.** per dozen; **8s.** per gross, Carriage Paid. Supplied by all Nurserymen, Florists, &c.

FOWLER'S LAWN SAND

TRADE MARK.

(INTRODUCED IN 1877).

A Certain and Effectual Destroyer of Daisies, Plantains, and Weeds generally, so troublesome and unsightly on Lawns. A renovator also of old and decayed Lawns.

All Lawns should be dressed at least once a year with this article, its fertilizing properties being equal, if not superior, to anything at present offered.

PRICES—In Tins, 1s., 2s. 6d., 5s. each.
In Casks, ¼ cwt., 8s. 6d.; ½ cwt., 16s.; 1 cwt.; 30s. each.

MANUFACTURERS,
CORRY & CO., Ltd.,
FINSBURY STREET, LONDON, E.C.

To be had of the Seed and Nursery Trade generally.

TREE TOMATO.

A valuable novelty of recent introduction. Easy to grow (see illustration, "Amateur Gardening," April 16th). Plants, 3 for 2s., 6 for 3s., or 5s. per doz. Carriage paid for cash with order.

The **Best Variety** of the usual style of Tomato is the new "**Up-to-Date,**" which is also good for open-air culture. Seed, in packets, 1s. and 2s. each, or plants 2s. per doz. Carriage paid cash with order.

ROBERT HOLMES, Norwich.

1898 FORBES' CATALOGUE 1898

(over 150 pages—nearly 150 illustrations) of **FLORIST'S FLOWERS and HARDY BORDER PLANTS** is got up REGARDLESS of TROUBLE or EXPENSE, with the result that it is by UNANIMOUS CONSENT pronounced the most COMPREHENSIVE, most ACCURATE, most RELIABLE, most COMPLETE, and BEST EXTANT.

It gives full and ACCURATE DESCRIPTIONS of every thing in the way of FLORIST'S FLOWERS, also COLOUR, HEIGHT, TIME of FLOWERING, and PRICE of all the best HARDY BORDER PLANTS, together with their ENGLISH or COMMON NAMES, and a mass of other VALUABLE INFORMATION that cannot be had elsewhere.

It is, in fact, a veritable REFERENCE-BOOK, invaluable to all growers of these plants, and should be in the hands of all intending purchasers. Free on application.

JOHN FORBES, Nurseryman,
HAWICK, SCOTLAND.
ESTABLISHED 1870.

DAHLIAS.

H. CANNELL and SONS, sole introducers of the Cactus and Single Varieties, beg to assure all admirers of this family that they have for 25 years been awarded Highest Honours for the best General Collection, and that their Stock of 40,000 in 600 varieties is the completest and best kept in England, and give the greatest satisfaction from one end of the world to the other, as a proof append the following:—

G. Herbert Hasyard, Esq., Charlottetown, Prince Edward Island, North America. 31/3/93.

"I wish to thank you for dahlias. I got some from four different places in England, which more or less failed. Whereas all yours are fine plants."

Send for Illustrated Catalogue, free to coming customers.

NESLING, Ganarew Cross, Monmouth.

GARDENER (Head); where two or more are kept; age 27; single; life experience in all branches Inside and Out; excellent character.—W. PETERS, Gardens, High Firs, Harpenden, Herts.

GARDENER (Head); age 35; thoroughly experienced Inside and Out; early and late forcing; 6½ years head in present place.—A. STOCK, Gardens, Bury Hall, Alverstoke, Hants.

GARDENER (Head Working) where others are kept; married; age 34; one child; life experience in all branches (including orchids and pines); good testimonials.—G. F., Church House, Rowner, Gosport.

GARDENER (Head Working, or good Single-handed); 15 years' good practical experience in all branches; first-class references; age 30; married when suited.—G. BOWYER, Normandy, Guildford.

GARDENER (Head Working), age 30; life experience; thoroughly understands flowers, fruit, and vegetables, including orchids and carnations; well recommended by present and past employers.—DAWSON, Rangemore Gardens, Burton-on-Trent.

GARDENER (Head Working), age 40; married, no family; good practical experience in all branches; one year's good character, 7½ previous.—CROCKFORD, The Gardens, Ham Manor, Angmering.

GARDENER (Head Working); married; age 40; thoroughly experienced and practical in all the branches; 12 years' excellent character as head from present employer.—W. BALL, Bramcote, Notts.

GARDENER (Head Working); age 39; married, one child, 12; thoroughly practical in all branches; 25 years' excellent characters; land stock if required.—STEVENS, 83, Wood Street, High Barnet, Herts.

GARDENER (Head Working).—Mr. G. CLIFFE, Gardener to Earl Egerton of Tatton, wishes to RECOMMEND his General Foreman, G. Howe; previous 2 years foreman, Stoke Park, Slough; 14 years' experience.—HOWE, Tatton Gardens, Knutsford.

GARDENER (Head Working); age 30; life experience in orchids, early forcing, vines, peaches, melons, cucumbers, fruit, flowers, kitchen garden, and pleasure grounds; thoroughly competent in all branches; highest references.—A. W. SMITH, Merrylands Cottages, Bookham, Surrey.

GARDENER (Head Working, where one or more are kept); well up in all branches both Inside and Out; can be highly recommended; age 29; small family.—W. HINTON, Grove Lodge, Epsom.

GARDENER (Head or good Single-handed); life experience in vines, melons, cucumbers, tomatos, stove and greenhouse, fruit, flowers, and vegetables; age 40; married, no family; good character.—GARDENER, Elm Cottage, Rickmansworth.

GARDENER (good Single-handed); age 32; married, no family; thoroughly experienced; six years' good character from present employer.—R. HODGES, Court Lodge, West Farleigh, Kent.

GARDENER; single; age 25; 10 years' experience in nursery and large private establishments; experience in all branches under glass, and decorating; excellent references; no objection as to kind of situation.—H. EAST, 45, Martin Road, Woodside Green, South Norwood.

GARDENER (Single-handed); age 23; nine years' experience in vines, peaches, orchids, stove and greenhouse plants, flower and kitchen garden, also wreath and bouquet making; good references.—L. SMITH, 9, Carthew Villas, Hammersmith.

GARDENER (Single-handed, or Second); eight years' experience; fours years in present situation; age 24.—Address GEORGE CAPES, care of W. Campbell, Esq., Grove House, Caister, Lincs.

GARDENER (Single-handed, or with help); understands vines, greenhouse, flower and kitchen garden, and the general routine of the business; seven years' excellent character; disengaged; age 43; married, no family; total abstainer.—W. SHILVOCK, near The Reform, Bridge Road, Maidenhead.

GARDENER (Single-handed, or good Second); age 24; 8 years' practical experience Inside and Out; good characters; disengaged.—W. BARRON, Poona House, Cosham, Hants.

GARDENER (Single-handed, or Under) where two or three are kept; understand horse; age 26; abstainer.—T. CHURCH, 66, High Street, Nelson, Treharris, Glamorganshire.

GARDENER (Single-handed); age 25; married when suited; seven years' experience in good gardens; Inside and Out; excellent references from past and present employers.—G. MANN, The Gardens, High Firs, Harpenden, Herts.

GARDENER (Second); Inside and Out, SEEKS SITUATION in private establishment; age 25; 10 years' experience; good character.—C. DOMAN, care of Mr. Warriner, Grange Road, Egham, Surrey.

GARDENER (Under, or Single-handed); used to kitchen garden and greenhouse work; six years' character; age 20.—A. DANIELS, Oakhurst Court Gardens, South Godstone, Surrey.

GARDENER (Under or Journeyman); age 22; seven years' experience; good references; abstainer.—A. HIBBERT, Church End, Arlesey, Hitchin, Herts.

JOURNEYMAN (Inside, or Inside and Out); age 21; having been in last situation 2 years can be well recommended; bothy preferred.—E. FRYER, The Lodge, West Drive, Brighton, Sussex.

JOURNEYMAN (Under); Inside, or Inside and Out; in good Private Establishment; age 19; good experience; bothy preferred.—J. TREAGUS, Waldeck Cottage, Lyne Lane, Chertsey, Surrey.

JOURNEYMAN (First); Inside, or Inside and Out; 3½ years' good character present situation; age 22; disengaged; bothy preferred.—H. BENTLEY, Glebe Cottages, Pluckley, Ashford, Kent.

JOURNEYMAN (First) Inside.—The Head Gardener, Les Altes, Isle of Wight, can highly RECOMMEND a young MAN, age 24, as above; eight and a half years' experience in good gardens; three years in present situation; bothy preferred; good references.

JOURNEYMAN (Inside); age 20; private or nursery; strong, active, and willing; six years' experience; three years in present situation; can be well recommended; disengaged; bothy preferred.—F. BURT, 190, High Road, Kilburn.

RICHARD SMITH and CO., beg to announce that they are constantly receiving application from Gardeners seeking Situations, and that they will be able to supply any Lady or Gentleman with particulars, &c.—St. John's Nurseries, Worcester.

UNDER-GARDENER, or Single-handed, by young man, age 22; with knowledge of orchids; good references; state wages; London or suburbs preferred.—ARTHUR, Tanswell Stores, Earl's Colne, Essex.

WANTED, SITUATION (Inside, or Inside and Out); age 21; experienced in peaches, tomatos, grapes, &c.; please state wages; abstainer.—F. WERNHAM, Well House, Newbury, Berks.

WANTED, SITUATION as Under Gardener, or Single-handed; good experience; married; age 22; last place five years.—PERCY HARE, Brafferton, York.

YOUNG MAN, 21, SEEKS SITUATION as Under Gardener; six years' experience; Inside and Out; good character.—Apply H. BUTLER, Angel Inn, Henley-on-Thames.

YOUNG MAN, age 28, REQUIRES SITUATION as Under Gardener; good character from last place. F. RADBOURNE, Woodspeen West, Newbury, Berks.

YOUNG GARDENER (age 22), wishing a CHANGE of Situation, seeks same under a good practical man; over five years in present situation; highest character and recommendation; total abstainer.—F. G., Mere, Bath.

Situations Vacant.

WANTED (at once), YOUNG MAN; must be quick at his work; potting, propagating all for nursery; state wages and references.—GEO. BLUNDELL, Florist, Friern Barnet, Whetstone.

NOTICE. AN EMPLOYMENT REGISTRY DEPARTMENT IS CONDUCTED IN CONNEXION WITH THE "GARDENERS' MAGAZINE," AND THE CHARGE FOR AN ADVERTISEMENT INCLUDES A FREE ENTRY ON THE REGISTER FOR ONE MONTH. IF NOT SUITED AT THE END OF THAT TIME, AND IT IS DESIRED THAT A NAME SHOULD REMAIN, IT WILL BE CONTINUED FOR A FURTHER PERIOD UPON RECEIPT OF A REQUEST, IMMEDIATE NOTICE MUST BE GIVEN WHEN AN ENGAGEMENT IS SECURED.

A List of Gardeners on the Register will be supplied upon application to the Publishers if a stamped envelope is forwarded, addressed 148 and 149, Aldersgate Street, London, E.C.

NATIVE GUANO.

BEST AND CHEAPEST MANURE FOR GARDEN USE.

Price **£3 10s.** per ton in bags. Lots under 10 cwt., **4s.** per cwt., 1 cwt. sample bag sent carriage paid to any station in England on receipt of P.O. for **5s.**

Extracts from 22nd annual collection of reports:—

NATIVE GUANO FOR POTATOS, VEGETABLES, &c.

C. H. TINDALL, Bardney: "Used for Potatos. Result very satisfactory; yield much above average. A splendid manure." G. WATTS and SONS, Bournemouth, report: "Good for general purposes. Grand for all Root Crops, Tomatos, and Cucumbers. Find it so cheap; and it does not exhaust the ground like other manure."

NATIVE GUANO FOR FRUIT, ROSES, TOMATOS, &c.

L. F. USHER, Sidcup: "Potatos and carrots, splendid crops; Peaches, Nectarines, &c., splendid. Should not like to be without it on any consideration." G. STONARD, Gardener to Sir A. T. Watson, Bart.: "Used for seven years for Peaches, Grapes, Tomatos, Cucumbers, Roses, and Chrysanthemums with excellent results."

Orders to the **Native Guano Co. (Limited)**, 29, New Bridge Street, Blackfriars, London, where pamphlets of testimonials, &c., may be obtained. Agents Wanted.

DOBBIE & Co.'s ANNOUNCEMENTS.

DAHLIA PLANTS.

WE are now busy sending these out to all parts of Britain, and to many continental countries. Those who have not already ordered, and who are desirous of having Dahlias early in bloom, should send in their orders at once. When received (in Neponset paper flower-pots if desired with balls of soil whole), they should be potted into 4-inch pots in nice, rich, open compost, and grown on for two or three weeks in a warm house or frame, afterwards gradually hardened off, and planted out 1st June. This is the way to obtain plants which will begin blooming in July.

We grow the best, and only the best, varieties in all the different sections—

Show and **Fancy, True Cactus, Decorative, Pompone, Single,** and **Single Cactus,**

and offer our Selection at the uniform price of

5s. per dozen (in Neponset pots, 5s. 6d.), carriage paid.
35s. per 100 (in Neponset pots, 38s.), carriage paid.
(In not less than 50 varieties.)

Special Offer of the following Splendid New Cactus Varieties of 1897 :—

Bridesmaid, Cedric, Cinderella, Cycle, Fantasy, Starfish Flossie, Ensign, Jessie, H. Stredwick, Iona, Mrs. Kingsley Foster.

The **12** for **15s. 6d.**, post free. Any **6** for **8s. 6d.**, post free, in Neponset pots. Single Plants, **1s. 6d.** each, post free, **1s. 9d.**

Buyers wishing to make their own Selections can have Catalogues on application.

THE DAHLIA: Its History and Cultivation.
A Handbook for all Growers.

The *Leeds Mercury* says: "With the aid of this pretty illustrated volume the cultivation of this superb flower should present no difficulties to anyone." Price, in stiff paper covers, 1s.; in cloth boards, 1s. 6d.; post free.

NOTICE TO ADVERTISERS.

Owing to the continued increase in circulation, the "Gardeners' Magazine" now goes to press on Wednesday. No advertisement can be guaranteed insertion, or altered, unless received before Four p.m. on that day.

NOTES OF THE WEEK.

PLANT NAMES.

No true lover of flowers or plants of any sort is satisfied with vague generalisations, and just as the lover of his fellow-men must needs start a friendship, or even an acquaintanceship, by learning the name, at least, of a fresh introduction, so the real admirer of a new plant cannot rest until its name be known to him in like fashion. Unfortunately, as horticulture has developed, and almost every flower has yielded variety after variety, each one demanding some special appellation, the faculty of memory has become so severely taxed that it is only the specialist who can retain them, and then even only in his own particular branch. The very names of species as compiled at Kew fill several huge volumes, while many of these have varied in scores, and it may be in hundreds, of ways, so that eventually the botanist proper washes his hands of the matter, the scientifically descriptive names upon which the memory might fix are dropped, and the plants are christened arbitrarily with the names of men and women of note or otherwise, or in any fantastic fashion which serves to distinguish them from the crowd. It is also a matter of constant complaint that the same plant is differently named by different people, and this occurs by no means exclusively among non-botanical folk, as a list of scientific synonyms will speedily show. In this particular connection the up-to-date botanist and would-be reformer finds himself handicapped and saddled with an inheritance of misnomers which have become so well known as referring to certain plants that revision simply means further confusion. Even names which are based on recognised specific characters, such, for instance, as the shape and position of the sporeheaps in ferns, are applied to varieties of species which present other characteristics altogether, so that our common lady fern and its mountain sister (Polypodium alpestre) are actually classed both with the polypodies and the spleenworts, two extremely distinct tribes, though they are properly members of neither, but of a quite distinct one. The shield and male ferns are both included in one genus of aspidium as an example of the opposite or "lumping" system, a result of which is that in one of our best text books on the subject one and the same fern is termed aspidium, nephrodium, and lastrea in the text and the illustrations, and in certain lists referring to both. This may undoubtedly be called hairsplitting, but it is, rather, headsplitting; and we cannot wonder that the question of nomenclature becomes a bugbear, for "who shall decide when doctors disagree," and how can we consistently blame Tom, Dick, and Harry for haphazard names when confusion reigns at headquarters? The difficulty arises in two ways—the botanist has his naming work to do very often on the strength of dried specimens and descriptions, which may quite well convey an erroneous notion and lead to a misleading name: he has also to deal with a very wide field, so that it is impossible for him to know as much of the living plants as those who grow them and know them from a better point of view. With the breeder of new forms, the same variety often arises in different hands, and hence gets a different name, all of which points to the value of a single centre of reference as the cure, though such a cure can only be partial, the evil being just as sporadic and recurrent as the "sports" themselves.

PROSPECTS OF THE FRUIT CROP.

THE great plantations of cherries, pears, and plums in Kent, and other of the fruit-growing counties, are now in the full flush of their floral beauty, and the billowy masses of snow-white blossom that greet the eye on all sides add immensely to the charms of the landscape, and give rise to considerable speculation as to the ultimate results of this prodigality of floral wealth. It is yet too early to forecast the fruit harvest of the current year, for a severe frost or a comparatively short period of cold weather is sufficient to destroy the embryo fruits, and reduce the crop to within a measureable distance of the vanishing point. Already we have received several complaints of the injury that has been done in pear and plum orchards by night frosts, and in two or three instances both pears and plums are said to have had their flowers completely destroyed. These facts notwithstanding, we regard the prospects of the crop of each of the three kinds mentioned as distinctly hopeful, and we have little doubt that should the climatic conditions be favourable there will be abundant supplies. Apple trees are just beginning to unfold their rose-tinted buds, and in a short time hence will contribute materially to the beauty of the country districts. In the more southern counties the apple trees are already in bloom; but unlike those of the pears, the plums, and the cherries, the flowers were not sufficiently developed to expose their organs of reproduction to the keen easterly winds and sharp frosts that did considerable damage in some districts to other fruits. There is not only a greater profusion of blossom this year of the whole of our orchard fruits, but by reason of the thorough maturation of the wood in the autumn, the flowers are more perfectly developed than was the case in the spring of 1897, and therefore are better able to withstand the adverse influences to which fruits grown in the open in the United Kingdom are exposed. This fact, taken in connection with the highly favourable change that has taken place in climatic conditions during the past few days, fully justifies the anticipation of heavy crops of our commonly grown hardy fruits.

MANURES FOR TOMATOS.

THE question of the most suitable fertilisers for tomatos is of considerable importance to a very large number of cultivators, and any information that will assist in its solution is well deserving of careful attention. In the current issue of the Royal Horticultural Society's journal, Mr. W. Neild gives in his paper on the cultivation of tomatos, some particulars of the experiments he has conducted during the past two years with a view to determine the best manures for these much appreciated esculents. In carrying out the 1896 experiments, to which alone we shall now refer, the plants were at their final shift put singly into ten-inch pots, and the soil used was "a heavy and adhesive" loam from a pasture. Nothing, we learn, was added to the soil excepting a small quantity of lime rubble for the purpose of supplying the plants with lime and keeping the compost open. On receiving their final shift the plants were divided into ten batches, the following manures applied fortnightly, after the food constituents in the soil had been exhausted, at the rate of one-eighth of an ounce to each plant, and when more than one manure was used, the several kinds were mixed together in equal proportions: (1) Nitrate of soda and muriate of potash; (2) superphosphate of lime, muriate of potash, and sulphate of iron; (3) sulphate of ammonia and muriate of potash; (4) muriate of potash, sulphate of iron, and nitrate of soda; (5) sulphate of iron and muriate of potash; (6) muriate of potash; (7) sulphate of iron; (8) nitrate of soda; (9) sulphate of ammonia; (10) superphosphate. The results obtained were exactly what might have been expected. Nos. 2, 5, 6, 7, and 10 were failures, the fruit being undersized, and the foliage had a yellow, sickly appearance. Nos. 3 and 4 produced a moderate crop, and the plants were fairly healthy; Nos. 1, 8, and 9 made a vigorous growth, and yielded an excellent crop, but hardly equal to that obtained from plants that were supplied with liquid manure from the stables. No figures are given with regard to the weight of the crop, but it will be seen that the best results were obtained from nitrate of soda and sulphate of ammonia when used alone than when combined with muriate of potash, and we are not surprised that this should have been so. Without an analysis of the soil we are not in a position to speak positively with reference to the percentage of potash, but as the soil is described as heavy and adhesive, it is safe to assume that it contained sufficient potash for the requirements of the plants, and that nitrogen alone was required to enable them to make a vigorous growth. Mr. Neild, in his comments on the results, observes: "Potassic manures have long been considered the best for tomatos, and yet when muriate of potash was applied by itself it proved to be a failure," an observation showing that much has yet to be learnt with regard to the food requirements of plants and the application of manures.

There can be no question as to the value of potassic salts as a constituent of the food of the tomato, but they must be in suitable form and proper proportions. In Mr. Neild's experiments the muriate of potash was applied so liberally that at each application the dressing was equivalent to nearly four cwt. per acre, and assuming four dressings were given, we have a total of sixteen cwt. per acre, a quantity so large that it must have seriously affected the health of the plants. Moreover, the muriate is not the best form in which to apply potash to the tomato as to some other crops, as, for example, potatos, tobacco, and sugar beets. Used in moderate quantities it tends to render potatos waxy in texture, to reduce the quantity of crystallisable sugar in beet, and to impair the flavour of the tobacco leaf, and the injurious effect produced is considered to be due to its tendency to give rise to the formation of calcium chloride, a compound more or less injurious to plant life. Potash and phosphates are not sufficiently active to admit of their being profitably used as fortnightly top-dressings, and the preferable course is to mix them with the compost when being prepared, and in moderate quantities, the necessity for this course being brought into strong relief by the results of Mr. Neild's experiments. These results are also useful in reminding cultivators that plants should not be supplied with an excess of some one constituent of their food, but must have, to ensure their full development, the whole of the constituents in proportions adapted to their requirements.

Fertility of Hybrid Orchids.—Before Darwin published his "Origin of Species" it was an article of common belief that distinct species were seldom fertile with each other, and that if hybrids were raised at all they were sterile. Darwin made an elaborate study of the question, and as the result came to the following conclusion: "First crosses between forms sufficiently distinct to be ranked as species, and their hybrids, are very generally, but not universally sterile. . . . The sterility is of all degrees." In "Animals and Plants Under Domestication," Darwin observes, "The sterility of distinct species first united and that of their hybrid origin graduates by an almost infinite number of steps from zero up to complete fertility. . . . This high degree of fertility is, however, rare." Dr. Alfred Wallace held similar views, and so late as 1890 he stated in "Darwinism" "Distinct species on the other hand, however closely they may resemble each other externally are usually infertile when crossed, and their hybrid offspring absolutely sterile." Yet it is recorded that 783 hybrid orchids have flowered, 485 of which were obtained from crosses effected between distinct species, and 248 from the inter-crossing of hybrids. With reference to this interesting question Mr. C. C. Hurst cites in his "Notes on Some Curiosities of Orchid Blending" in the current issue of R.H.S. Journal some figures placed at his disposal by Mr. Reginald Young, of Sefton Park, Liverpool. Taking the East Indian cypripediums, Mr. Hurst states that Mr. Young has made 577 crosses among thirty distinct species, and fifty-three distinct hybrids during the past five years, crossing species with species, species with hybrids, hybrids with species, and hybrids with hybrids, and all under uniform conditions. Out of these 577 crosses Mr. Young succeeded in obtaining 452 pods of good seed, which represents 78·3 per cent. fertile. An analysis of these figures shows that out of 188 crosses between distinct species 179 pods of good seed were obtained, a degree of success difficult to excel even in crosses between varieties of the same species, representing as it does 95·2 per cent. fertile. While out of 389 crosses in which a hybrid was concerned in the parentage 273 pods of good seed were obtained, being 71·8 per cent. fertile, showing a decrease of fertility of 23·4 per cent. in crosses between hybrids as compared with crosses between species. This seems to point to the conclusion that in this cypripedium group while crosses between distinct species are almost, if not quite, as fertile as crosses between varieties of the same species, yet crosses with hybrids, though fertile to a very large extent, are yet slightly less fertile than crosses between species. What is the cause of this slight decline in the fertility of hybrids? From Mr. Young's experiments it seems to be due in a large measure to the loss of power in the male element of the hybrid. For out of 143 hybrids crossed with the pollen of pure species 128 fertile pods were obtained, or 89·5 per cent., showing a very slight loss of power in the female element of the hybrids of 5·7 per cent. While out of 118 pure species crossed with the pollen of hybrids only sixty-seven pods of good seed were obtained, showing 56·7 per cent. fertile.

Smooth-leaved Kales.—It is a fortunate circumstance that the destructive fungus which so generally destroyed the smooth-leaved kales at Chiswick connected with the kale trial there, and in other places in the metropolitan area, does not seem to have extended to the provinces. Certainly, it has not been found everywhere. We very recently saw at Norbiton remarkably nice clean breadths of that hardy kale, Chou de Milan, and later at Hackwood Park, Basingstoke, a fine breadth of delicious Breda kale. It was this variety, the asparagus, Ragged Jack, and similar ones that were so entirely eaten up by the fungus at Chiswick and elsewhere. The Breda is held in very high esteem at Hackwood, and it was evident that at this time of the year a good breadth in perfect health must be a blessing to any gardener. It is to be hoped that these fungus troubles may be of but a temporary nature, and that in a year or two hence all our borecole stocks may be as free from them as the curled ones have been.

Lovers of Curious Orchids, especially of that section known horticulturally as "botanical," will find a large number of interesting species now flowering in the orchid houses at Kew. Some few of the species are sometimes found in private collections, such as Masdevallia Ephippiam, Maxillaria Houtteanum, Cochlioda rosea, Epidendrum elongatum, and Ærides Sandarum; but where only the showiest of orchids are grown these are taboed. A few of these tiny orchids are Maxillaria sanguineum, M. aciantha, a green-flowered Costa Rica [illegible] præstans, a yellow and red brown Guatemalan species; Lycaste [illegible] white and green, worth growing; Calypso borealis, a charming and [illegible] orchid; Disperis capensis and Holothrix villosa, two other terrestrial [illegible] Bletia gebina, Odontoglossum retusum, brown and yellow; Polystachya [illegible] Ornithidium nanum, Epidendrum Linkianum, and E. stenopetalum, [illegible] with white centre to the lip. Those whose knowledge of orchids does [illegible] beyond varieties and hybrids of odontoglossums, cattleyas, and cypripediums, would obtain a fair idea of the enormous variation of form and growth the order contains, by a visit to the Kew collection.

Germination of Beet Seed.—The seed of the beetroot, as cultivators are aware, materially differs from that of other of the vegetables grown in British gardens, and sometimes perplexes those who, not acquainted with its peculiarity, conduct experiments with a view to determine its germinative power. The "seed" of two or three true seeds is enclosed in the hard corky calyx of the parent flower. Hence, when the "seed" germinates in the ground, two or three young plants present themselves at one spot, and this makes the crop more difficult to hoe effectively than is the case with other root crops. But there is an earlier trouble than the one incident to hoeing with which cultivators are not unfamiliar, and that is the uncertainty of germination. An investigation, conducted at the Wisconsin Agricultural Experiment Station, on the influence of varying amounts of water on the germination of beet seed, throws some light on the matter. In the experiment the seeds were placed for germination in asbestos cloth—a drier cloth, containing approximately 87 per cent. of water by weight at the beginning of the trial and 83 per cent. at the end, and a wetter cloth, holding about 92 per cent. of moisture at the beginning and 111 per cent. at the end. The average germination from the two testers showed a difference of fifty seeds for each hundred seedballs—as they are not inappropriately termed—in favour of the drier cloth. It would appear, therefore, that the germination of beet seed in the open ground is liable to be prevented by excess of water in the soil.

New Roses that have the promise of proving useful for enhancing the charms of the garden are sure of a warm welcome, and the new climbing roses presented to public notice by Messrs. Paul and Son at the R.H.S. meeting on Tuesday last did not fail to obtain a full share of attention. They were named respectively The Dawson and Psyche, and the first is a variety raised in the Arnold Arboretum from a cross between the single-flowered Polyantha and General Jacqueminot, and has been grown at Kew for several years past. It has a vigorous free-flowering habit, and produces large clusters of small flowers of a pink colour. We gave a characteristic illustration of this charming rose in the volume of the GARDENERS' MAGAZINE for 1896. Psyche was raised at Cheshunt from Golden Fairy, a dwarf-growing polyantha, fertilised with the pollen of Turner's Crimson Rambler, and has a scandent habit, the growth and foliage closely resembling that of the pollen parent, and the flowers are about two inches in diameter, quite double, flesh pink suffused with carmine rose. The plants shown, although only about fourteen months from the graft, were about six feet high, and were clothed with foliage and flowers from the rim of the pot to the apex. Psyche should prove a valuable companion to Crimson Rambler, and one of our best climbing roses.

Vegetables are so limited in variety at this season of the year that the [illegible] comprehensive and otherwise excellent collection contributed to the meeting of [illegible] Royal Horticultural Society on Tuesday by Mr. George Wythes, of Syon Gardens, formed an interesting feature. The principal varieties represented [illegible] lection are enumerated in our report of the Fruit and Vegetable [illegible] the names are of value as showing that vegetables which may be had in [illegible] early in the spring are sufficiently numerous to admit of the maintenance [illegible] and excellent supply. Mr. Empson also had excellent vegetables in his [illegible] laneous collection.

Australian Medicinal Plants are plentiful, though at present [illegible] have been utilised, and these but to a limited extent. In New [illegible] such plants are abundant, many kinds being found in the immediate [illegible] Sydney, especially in the Parramatta district. One of the most common [illegible] wild penny-royal, a decoction of which is largely used as a tonic. [illegible] oil may be extracted from it, which may be employed both as a medicine and [illegible] means of imparting a pleasant odour and flavour to other ingredients. [illegible] plants of the Gentian family, plentiful enough in the spring, have proved [illegible] efficacious in certain stages of dysentery. The common native raspberry, [illegible] other species of Rubus, possesses astringent properties, which may one day [illegible] it a place in the colonial pharmacopœia; which already includes the native [illegible] saparilla, although, notwithstanding the latter abounds in the [illegible] Sydney, the bulk of the sarsaparilla used by colonial [illegible] country people frequently prepare an agreeable and [illegible] native plant, which costs nothing save the labour of collecting it. It is [illegible] by the name of Sweet Tea or Wild Liquorice. There is also a native [illegible] to the sassafras of the pharmacopœia, which possesses medicinal properties [illegible] but little understood. The native grape yields a rich [illegible] used as a gargle, to be good for sore throat. The native [illegible] perties in common with the European species, and the leaves are frequently [illegible] for making herb tea. Self-heal is plentiful and indigenous, as in Europe; [illegible] bitter and astringent, and occasionally used as a substitute for bark. The [illegible] in England, are supposed to be efficacious in healing cuts, hence [illegible] different species of native currant possess a powerful acid, capable of being [illegible] for flavouring sugar drops or employed as a substitute for lemon syrup.

The Pine Aphis (*Lachnus pini*) was found in [illegible] trees of Cedrus deodara about twenty feet high by a [illegible] the Board of Agriculture in January. The attack [illegible] the trees as to cause them to assume a yellowish hue, and consequently to give rise to some anxiety on the part of the owner. As pointed out in the Board's Journal, it is unusual to find aphids materially damaging plants and trees growing in the open thus early in the year, but there can be no doubt that the abnormal state of the weather until February greatly favoured the attack. Aphids are frequently found alive in winter, but seldom in sufficient numbers to cause injury to the plants on which they are found. The pine aphis attacks several species of firs, especially the Scotch fir, but is not often seen upon deodars. It is one of the largest of the British aphides. The wingless viviparous female is brown in colour, and, according to Mr. Buckton, there is also a darker variety. It has very long legs, particularly the hind pair, and an extraordinarily long beak or rostrum, with a spear-like point, with which it pierces the firs at the base of the "needles," and extracts the sap. Its body is covered with short hairs. Upon the needles of the pieces of deodars sent for examination to the Board little groups of fine white threads were seen, evidently produced by these aphides. The most serviceable remedy would, it is suggested, be to syringe the infested trees with solutions objectionable to the insect, so as to make its food distasteful. Nothing could be better for this than the composition used for freeing hop plants from their peculiar aphides, made by mixing eight pounds of soft soap and the extract of six pounds of quassia chips to one hundred gallons of water. This should be syringed all over the trees by means of garden-engines with strong pumps; or, if the tree is too high, knapsack machines for spraying may be used by men upon ladders. This must be done very carefully, and the syringing would probably have to be repeated.

Trillium grandiflorum is well known as one of the most beautiful hardy plants flowering in spring, but its value for pot culture is not fully recognised; hence the magnificent specimen exhibited at the R.H.S. meeting on Tuesday by Mr. Empson, the chief of the Ampthill House Gardens, is deserving of special mention. The specimen in question was about thirty inches in diameter, and was furnished with a profusion of its chaste snow-white flowers, and it created much interest among the visitors.

At the Swanley Horticultural College courses of instruction will be given during the summer, and open, for the first time, to non-resident students of both sexes. Professor Warrington, of Oxford, will deal with Soils; Professor Henslow will treat upon the Physiology of Plants; and the Messrs. R. and A. Dean will discuss Flower and Vegetable Culture. Courses of instruction in Bee and Poultry Keeping will also form part of the programme.

Vegetable Culture in Italy.—The cultivation of vegetables in Italy has been greatly extended of late years, and the exports of both fruits and vegetables have materially increased. The export of dried vegetables was 498,000 cwts. in 1895 and 794,000 cwts. in 1896, chiefly to Austria, Great Britain, France, Spain, and Portugal. No statistics are available as to the production of fresh vegetables, but cauliflowers, broccoli, artichokes, tomatos, and other fresh vegetables form an important article of export in the winter; the quantity sent abroad in 1895 was 315,000 cwts. and in 1896 380,000 cwts. Only 3,952 cwts. are stated to have been exported to great Britain direct in the latter year. The exports of preserved fruit and vegetables have steadily increased during recent years; in 1893 they amounted to 21,751 cwts., and in 1896 to 64,112 cwts., of the latter quantity 44,556 cwts. were shipped to Great Britain. The production of potatos is practically stationary. In 1870-74 the average yield was 14,121,000 cwts., it fell in 1883 to 11,196,000 cwts., but in the three years 1892-96 it amounted to an average of 14,411,000 cwts. The export in 1896, chiefly to Austria, Malta, and Germany. was 484,000 cwts.

Irish Nurserymen and Market Gardeners.—At a recent meeting of the Council of the Royal Horticultural Society of Ireland a brisk discussion took place with reference to the position of nurserymen and market gardeners under the provisions of the Local Government Bill. The outcome of the discussion was the passing of a resolution "That this Council of the Royal Horticultural Society of Ireland desire to urge on the City and County of Dublin Parliamentary representatives to endeavour to alter the proposed Local Government Bill to the extent of including all agricultural lands in urban districts, as well as rural districts, in the provisions of the Bill. That copies of this resolution be forwarded to the above members of Parliament."

Tacca Cristata, also known as Attacia cristata, is always an interesting plant when in flower, its nodding umbels of purplish flowers, surmounted by two large purple involneral leaves, attracting considerable attention by reason of their peculiar form. At present there is a large specimen of this Malayan plant flowering in the Stove at the Royal Gardens, Kew, and carrying eighteen large fully expanded umbels, besides a few others not yet opened.

Vine Cultivation in Bordeaux was not attended with the best results during 1897, for untoward weather, diseases, and insect pests combined to reduce the production of grapes and consequently the vintage also. Mr. Hearn, British Consul at Bordeaux, contends, however, that most vine diseases can be combated by liberal expenditure and extensive treatment. To the good cultivator phylloxera has few of the terrors that it has to the peasant who cannot afford to fight it. If the diseases only attack singly they may be beaten off by treatment, but when they come up in hordes, as they did in 1897, it is only the most robust vineyards that can make a stand against them. Mildew, blackrot, cochylis, and all sorts and conditions of other evils were rife in 1897, but after the mildew the most mischievous was probably the cochylis. This insect, which hibernates in a chrysalis state, comes forth in early spring as a brown and orange-yellow moth of the size of a house-fly, and lays its eggs on the plants, so that when the grub comes forth it can feed on the vine blossoms. Later generations of grubs finding no blossoms take kindly to the fruit, and so continue the work of destruction. Some success appears to have resulted from dusting the vines with a mixture of naphthaline and sulphur, but this has not been widely tried, and the cochylis certainly had it all its own way in the last vintage. It appears that the appearance of cochylis is contemporary with the destruction of small birds in the vineyards, for these are shot whenever possible, with the result that there is literally no bird life among the vines, and insect life reigns supreme. If the birds were only allowed they would go to the vines in search of grub, cochylis, or other kinds, and obtain for the proprietor a result which no amount of money can accomplish. The principal organ of the viticulturist interest states that "cochylis was last year one of the principal agents in the reduction of the vintage. In certain important vineyards the loss occasioned by this insect amounts to hundreds of casks. And yet this cannot be laid at the door of negligence, since we know of a property where from July 20 to September 10, 5,000 days' labour of women and children were alone employed in looking for and destroying the eggs and larvæ of this insect." Had the birds been allowed they would, says Consul Hearn, have willingly performed the work.

Zonal Pelargoniums at Ghent.—An exhibit that startled our continental friends not a little at the recent Ghent Quinquennial Exhibition consisted of a handsome and extensive display of large bouquets of finely-developed zonal pelargonium blooms from Messrs. H. Cannell and Sons, Swanley, Kent. These were shown in the style the firm has found most suitable during a long career, and one that is well known to visitors to our leading London and provincial displays. It is not necessary to particularise the varieties, but some idea of the effectiveness of the group will be gained from the statement that from ten to twelve dozen large bunches of blooms were set up over a groundwork of greenery. One of the very few silver medals awarded at Ghent for non-competitive exhibits goes to Swanley to show the jury's appreciation of Messrs. Cannell and Son's production.

A New Experimental Station at Garforth, near Leeds, is being established for the instruction of agricultural students. The County Councils of the East and West Ridings of Yorkshire are combining in this matter, and, under the supervision of Dr. Somerville, of the Durham College of Science, Mr. Haydon will at once commence experiments and give demonstrations. A vote of £1,500 has been agreed to as a vote towards expenses. Courses in dairying will be held shortly, and specialised instruction given to youths of fifteen years and upwards.

A New British Flora is in course of production by the Rev. E. F. Linton, who is taking the "London Catalogue" as his basis to work upon. Since the latest floras were published not a few "forms" of British plants and several distinct species have been discovered and described.

Botanists and Mycologists in the United States with officially Government positions number fifty. All but ten of the States possess a State botanist, while New York and Connecticut have two each. Altogether there are fifty-one State experiment stations in the United States.

BOTANICAL GARDEN FOR ABERDEEN.

The following is an abstract from the deed of trust by Miss Cruickshank for founding and endowing a botanical garden for Aberdeen: "The trustees, who constitute also the board of management, are the Principal (Sir William Geddes), the Professor of Botany (Dr. James W. H. Trail), and the Professor of Mathematics (Dr. Pirie), and their successors in their respective offices in the University of Aberdeen, and other three gentlemen whose successors fall to be appointed by the survivors from time to time as vacancies arise. There is to be handed to the trustees by Miss Cruickshank at Whit Sunday first a sum of £15,000 sterling, which is to be employed by them in providing, forming, and laying out and maintaining a botanical garden, with all necessary appurtenances, including provision for the teaching and study of botany as pure science, and as applied to arts and industries, and, in their discretion, the provision of a house as a residence for the keeper of the garden. It is provided that the keeper of the garden may, if the trustees think proper, be the professor of botany in the university, and they may appoint one of their own number to act as factor or cashier for the trust. The garden is to be known in all time coming as the "Cruickshank Botanical Garden," in memory of the donor's late brother, Dr. Alexander Cruickshank, and it is to be held by the trustees in all time for the use, enjoyment, and behoof of the University of Aberdeen, and of the general public, without any preferable right in either, except to such extent, if any, as it may be thought proper by the trustees, in furtherance of the trust, to set apart class rooms, laboratories, or other buildings for the special service of either body. The trustees, subject to the above declaration, are to prescribe such regulations for the use and control of the garden as they may think proper. It is specially provided that the bequest is, so far as the university is concerned, to be in supplement of the annual provision already made by the university court or from other public sources, or by other private donors, for the teaching of botany as above defined in connection with the university, and that if the University Court shall at any time withdraw or diminish their provision the trustees may divert the bequest to other purposes."

Commenting on this munificent gift to Aberdeen University, an Aberdeen correspondent says: Miss Cruickshank's gift of £15,000 is cordially appreciated by both town and gown, and on all sides the opinion is expressed that no more suitable form could have been adopted of perpetuating the memory of the late Dr. Alexander Cruickshank, the brother, whom it is the desire of the donor to honour. Dr. Cruickshank took an exceedingly warm interest in the welfare of Aberdeen University, and he was above all things a lover of Nature and of the sciences of which botany is a leading representative. As Sir William Geddes so well phrased it at the meeting at which intimation was made of the gift, it is a peculiarly happy circumstance that the memorial to Dr. Cruickshank's name should be associated with a science in which he was himself such a proficient. The fitness of the gift is no less noteworthy as regards the University itself. A botanic garden has long been felt to be one of the most urgent needs of the University. It has been an object ever dear to the heart of the popular professor who at present so worthily fills the chair of botany in the University, and the recently formed Endowment Association made the provision of a botanic garden one of its main objects. The public are to share in the advantages of the garden. The gift is for the use of the University, but combined with that there will be access for the public to the garden, and as far as possible to the collections within the garden. Summed up, the Cruickshank Botanic Garden will be a boon not only to the University of Aberdeen, but to the city as well, to the amenities of which it will form a notable and valuable addition.

NATIONAL AURICULA AND PRIMULA SOCIETY.

THE annual exhibition of this society was held in conjunction with the fortnightly R.H.S. meeting on the 26th inst, at the Drill Hall, Westminster. It was a moderate show, and the flowers of fair average quality, for although some were large and coarse others were of especial beauty, and so the balance was preserved. We have seen a more extensive display, and for this occasion the entries were larger than usual, but the cold nights of late have so kept auriculas and primulas from progressing that not a few intending competitors had insufficient flowers properly expanded to warrant them in competing. All things considered, the society is prospering, as was stated at the luncheon held after the prizes were awarded, at the Hotel Windsor, under the presidency of the Rev. H. H. D'ombrain, the veteran florist.

SHOW AURICULAS.

The first prize for a dozen dissimilar auriculas was won by Mr. J. Douglas, Edenside, Great Bookham, with a very neat set of plants carrying good trusses; the varieties were Negro (Pullman), Mrs. Dodwell (Woodhead), Mrs. Potts (Barlow), Greenfinch (Douglas), Acme (Read), Olympus (Douglas), Mr. Henwood (Barlow), Gen. Rudd (Woodhead), Black Bess (Woodhead), Marmion (Douglas), Dr. Hardy (Simonite), and George Lightbody (Headley); Mr. C. Phillips, Bracknell, second; Mr. W. Smith, Bishops Stortford, third; and Mr. J. T. Bennett-Poë, fourth. Mr. C. Phillips secured the chief award for half a dozen auriculas with pretty plants of Richard Headley, J. Simonite, Mrs. Henwood, Mrs. Barnet, G. Rudd, and Mrs. Phillips; Mr. Smith, second; and Mr. J. T. Bennett-Poë, third. The best four plants were handsome specimens of Mr. Dodwell, Abbé Liszt, Lancashire Hero, and Mrs. Potts, staged by Mr. J. Sargent, Cobham; the other prizes in order were awarded to Mr. A. S. Hampton, Reading; Mr. A. R. Brown, Birmingham; Mr. A. Fish, Broxbourne; Mr. W. Palmer, Shortlands; and Mr. J. Gilbert, gardener to Rev. L. R. Flood, Merrow.

The best pair of auriculas came from Mr. P. Hennell, Winchmore Hill, and were J. D. Horner and Acme; Mr. Sargent second, with Abbe Liszt and John Simonite; Messrs. A. R. Brown, A. Hampton, W. Palmer, and J. Gilbert followed, in order as mentioned. Mr. C. Phillips came first for a green-edged auricula. with an unnamed seedling; Mr. Sargent second, with F. D. Horner; Mr. J. Douglas third, with F. D. Horner, and Mr. Sargent fourth, with the same variety. In the class for one grey-edged auricula Mr. Sargent secured first prize, with Lancashire Hero; Mr. W. Smith second, with G. Rudd; Mr. W. Smith third, with Rachel; and Mr. J. Douglas fourth, with G. Rudd. The premier white-edged auricula was Heather Bell, shown by Mr. Sargent; Mr. Gilbert second, with Acme; Mr. J. Douglas third, with Acme; and Mr. A. R. Brown fourth, with Heather Bell. For a specimen self Mr. Fisk was first with Heroine, finely developed; Mr. J. Douglas second, with Mrs. Potts; Mr. Smith third, with Heroine; and Mr. C. Phillips fourth.

For fifty auriculas in not less than twenty varieties, the first prize was won by Mr. James Douglas, Edenside, Surrey, with a group of well-grown plants, the majority carrying large trusses. The varieties staged were Ajax, Black Bess (2), Richard Headley, Lady Churchill, Abbe Liszt (2), Rachel (2), Snowdon's Knight, Ruby, Acme (4), Monarch, Violet, Dinham, Miss Prim (3), Mrs. A. Potts (2), Blackbird, Ringleader, Lord of Lorne (2), Colonel Champneys (2), Seedling (2), Heroine, Heatherbell, Dr. Hardy, Sylvia, Dr. Kidd (2), Venus (2), Ariel (2), Negro, and Perseverance. There were three competitors in this class, and the second award was secured by the Guildford Hardy Plant Company, Guildford, the firm staging a very even set of neat plants. The leading varieties were Acme, Ariel, John Simonite, Pizarro, Rev. F. D. Horner, Mrs. Dodwell, Heatherbell, Mrs. Potts, Abbe Liszt, Phyllis, Beauty, Dr. Horner, Rolt's Green, Brunette, Sam Barlow, Heroine, Talisman, Dr. Kidd, G. Rudd, Lord of Lorne, Andrew Miller, Colonel Champneys, Snowdon's Knight, Sir W. Hewitt, and Alderman. The third prize was won by Mr. C. Phillips, Bracknell.

ALPINE AURICULAS.

Mr. C. Phillips easily won the premier award for twelve alpine auriculas with splendidly-grown specimens of Lady Clementine Walsh, Mrs. Gorton, Jubilee, Sister Mary, Edith Western, Regina, Vandyke, Perfection, Salwin, Evelyn Phillips, Gladys, and Mrs. Martin Smith. The second prize set came from Mr. J. Douglas, Edenside, who had good plants of Firefly, Echo, Dean Hole, Toujours Gaie, Urania, Queen of the East, Orelia, Britannia, Miss Amy Naylor, and Lord Dudley; the Guildford Hardy Plant Company won third place. Mr. J. W. Euston, gardener to Mrs. Whitbourn, Great Gearies, Ilford, was placed first for six alpine auriculas with splendid developments of Urania, Calypso, Tennyson, Schubert, Psyche, and The Bride; Mr. C. Phillips second with Salwin, Lady Llewellyn, Mr. Gorton, Gladys, Chastity, and Evelyn Phillips; Mr. J. Douglas, third; and Mr. J. J. Keen, Southampton, fourth. For four alpine auriculas distinct, Mr. J. Euston, was again first, his plants of Cimiez, Hiawatha, Rosy Morn, and Tennyson, bearing large full trusses of large true blooms; Mr. Walker, Reading, second; Mr. A. R. Brown, third; and Mr. J. Gilbert, fourth; there were eight exhibitors in this class.

The premier gold-centred alpine auricula was Clara, shown by Mr. C. Phillips; Mr. J. T. Bennett-Poë, second, with Dean Hole; Mr. Gilbert, third, with the same variety; and Mr. Phillips, fourth, with Clara. Mr. Phillips also scored for a single white or cream centred alpine auricula, showing Perfection; Mr. J. J. Keen, second, with Amazone; Mr. Douglas, third, with Edith, and fourth, with Toujours Gaie. There were two competitors in the class for fancy alpine auriculas, and here the Guildford Hardy Plant Company took the chief award with handsome examples of Full Moon, Belle, Twilight, Canary Cup, Old Gold, Khartoum, Moonlight, Buttercup, Russet, Innocence, Rosy Morn, and Harlequin. Mr. J. Douglas's second-prize set contained specimens of Rolt's Green, Golden Plover, Octavia. Melita, Old Gold, Lara, Sextus, Hypatia, Poppæa, Golden Oriole, Mauve Queen, and Acté. The premier alpine auricula in the show was a handsome specimen of Mrs. Martin Smith, shown by Mr. C. Phillips, Bracknell; this is a crimson, cherry, and gold form.

In the class for six auriculas, open only to those who have not hitherto won a prize, Mr. Purnell Purnell, Streatham Hill, was first with C. J. Perry, Acme, Abbe Liszt, Miss Prim, Colonel Champneys, and Black Bess; Mr. J. W. Euston second. Under similar conditions a class for six alpine auriculas was provided, and here Mr. G. H. Addy, Waddon, Surrey, came first followed by Mr. Euston and Mr. P. Purnell. The first prize seedling auricula was a rich deep purplish-blue self with fine white paste, shown by Mr. C. Phillips; it was named Mrs. Dranfield. Mrs. Barefoot, gold and crimson, was the best alpine seedling, but Miranda Phillips in the same way was a close second, and both gained certificates.

PRIMROSES AND POLYANTHUSES.

In the class for twelve fancy polyanthuses there were three competitors, and here the first prize was won by Mr. J. Douglas for freely-flowered specimens of yellow, white, crimson, rose, and violet forms, all with extremely large flowers; Mr. J. Dixon, Chelford, came second, and Mrs. Euston third. Mr. J. [illegible] again scored for a dozen primroses, a fine lot of plants but with [illegible] purple hues among them; there was no other competitor. Messrs. Paul [illegible] Cheshunt, easily won first prize for six double primulas distinct, showing [illegible] large pans; the varieties were alba plena, purpurea plena. Croussei [illegible] plena, sulphurea plena, and platypetala plena; the Guildford Hardy [illegible] pany came second, their set containing a pretty plant of Madame P[illegible].

There was keen competition for the prizes offered for a group [illegible] varieties of primula or auricula, arranged on a space of not more than [illegible] ficial feet. The first prize was secured by the Guildford Hardy [illegible] with a pretty set of fancy and alpine auriculas, arranged in a large bask[illegible] pieces of tufa; Mr. J. Douglas, third. Mr. Douglas scored for twelve [illegible] species, or well-marked varieties; these were P. Forbesi, P. pubescens, P. decora, P. japonica, P. verticillata, P. floribunda, P. rosea, P. Sieboldi, P. mollis, and P. intermedia; here the Guildford Hardy Plant Company came second, Messrs. Paul and Son, third; and Mr. P. Purnell, Streatham, a good fourth. The [illegible] six primulas came from Mr. J. W. Euston, and comprised P. floribunda, P. intermedia, P. auricula, P. Forbesi, P. verticillata, and P. obconica, all represented by fine specimens.

The four baskets of primroses and polyanthuses staged in competition made [illegible] very brilliant display; the best one was shown by Mr. J. T. Bennett-Poë, [illegible] contained a grand lot of freely-flowered plants, all high-class varieties; [illegible] Douglas was second, and Messrs. Paul and Son, third.

NEW PLANTS AND FLOWERS.

LÆLIO-CATTLEYA WELLSIANA LANGLEYENSIS.

A BEAUTIFUL orchid with soft rose petals, and blush sepals, and a magnificent purple lip of the shape of Lælia purpurata. The hybrid was obtained by crossing L. purpurata with C. Trianæ, the former being the pollen parent; the [illegible] measure six inches across, and have the appearance of a glorified L. purpurata. The lip has a violet purple tube, and a rich royal purple apex of great breadth and depth; in the throat is a small soft buff area that adds to the beauty of the flower. F.C.C., R.H.S., April 26. Messrs. J. Veitch and Sons, Chelsea.

ODONTOGLOSSUM HUNNEWELLIANUM MAJUS.

This is a superb form of a somewhat rare orchid. Its flowers are three inches across. The sepals are yellowish, barred with rich red-brown; the petals are whitish, yellow towards the tips, and spotted and blotched with red brown. Lip creamy white, crisped, and waved, and with a few small red dots. A.M., R.H.S , April 26. Mr. H. Greenwood, Highfield, Hazledene.

CATTLEYA SCHRÖDERÆ HAREFIELD HALL VAR.

A fine cattleya of good shape, and remarkable for the violet [illegible] at the apex of the lip. Sepals and petals are blush tinted. The lip is pale [illegible] tinted and has a very broad, spreading mouth; there are two yellow patches behind the violet purple shading, while the fringed margin is softest rose blush. A.M., R.H.S.. April 26. Mr. Holbrook, gardener to E. Ashworth, Esq., [illegible] Hall, Wilmslow.

CYMBIDIUM CANALICULATUM VAR.?

A curious deciduous species bearing a long spike of forty-five [illegible] black flowers; the tiny lip is whitish in the centre, and with [illegible] margins. The plant is stated to come from Queensland. A.M., R.H.S., [illegible] Mr. D. Smith, gardener to J. Sparks, Esq., Heathcote, Ewhurst, [illegible]

CATTLEYA SEDENI.

This is a pretty hybrid cattleya, obtained by crossing C. Lawrenceanum with C. Percivaliana. The sepals are very substantial, and of a soft rosy-purple shade; the broad and upstanding petals are of a similar colour; the lip has a long tube and spreading mouth betraying its Lawrenceanum parentage. The rose-purple shade is here evident, but the spreading apex is deep purple, shaded with crimson-purple, and with an orange-shaded throat. A.M., R.H.S., April 26. Mr. [illegible], gardener to C. L. N. Ingram, Esq., Godalming.

RICHARDIA RHODESIA.

A splendid golden spathed richardia with huge spathes of a rich and dark golden hue; very broad and full and with the tip much deflected. It is a strong grower and has stout spotted foliage. A.M., R.H.S., April 26. Mr. Jennings, gardener to Leopold de Rothschild, Esq., Ascot.

PTERIS SUMMERSI.

A particularly fine pteris of sturdy but elegant growth and provided with fronds that are much divided and have all the principal pinnæ heavily divided and crested at the apex. This handsome Ribbon Fern may be considered as a [illegible] and heavily crested form of the now well-known P. Wimsetti, from which it is no doubt a seedling. A.M., R.H S., April 26, Mr. H. B. May, Edmonton.

AZALEODENDRON EDOUARD ANDRE.

This is a hybrid between Azalea Mollis and Rhododendron [illegible] flowers have shortened tubes and are of a soft rosy hue, a pretty shade, [illegible] spottings of dark brown on the upper segments. An interesting plant. F.C., R.H.S., April 26. Messrs. J. Veitch and Sons, Chelsea.

AURICULAS.

Mrs. Barefoot, a gold-centred alpine auricula of large size and fine shape; [illegible] segments are blackish-crimson at the base, a paler shade spreading almost [illegible] the pale gold ground, the latter being observable at the margin. F.C.C., N.A. and P.S., April 26. Mr. Barefoot, Croydon.

Miranda Phillips.—Another fine gold-centred auricula with rich crimson [illegible] to the segments and broad dull gold margins. F.C.C., N.A. and P.S., April 26. Mr. C. Phillips, Bracknell.

Firefly.—A splendid free-flowering alpine auricula, with rich gold centre [illegible] brilliant cherry-red segments that have dark crimson bases. F.C.C., N.A. [illegible] P.S., April 26. Mr. J. Douglas, Edenside.

ROSE PSYCHE.

This is a fine hybrid polyantha rose, with palest rose-tinted flowers of [illegible] size and very double; the shade may almost be called blush. This is a [illegible] free-flowering variety obtained by crossing the polyantha rose Golden [illegible] with Turner's Crimson Rambler. A.M., R.H.S., April 26. Messrs. Paul and Son, Cheshunt.

AZALEA J. J. DE VINCK.

An effective mollis azalea, with large trusses of broad [illegible] a soft shade upon which the bright brown spots that occur on the [illegible] show up forcibly. A very distinct mollis azalea, or [illegible] obtained by crossing mollis with sinensis varieties. A.M., R.H.S., [illegible] Messrs. R. and L. Cuthbert, Southgate.

HARDY APRIL FLOWERS IN 1898.

AFTER the winterly storms and severe frosts of March, hardy flowers in the middle of April are neither more backward or more forward than usual at this season, but their flowering is decidedly above the average. I mention a few of those in flower in this garden between the April 10 and 20. The flowering of all the daffodils has been very good, and the colours of those with orange crowns is rich and full, as generally happens when they progress in bud slowly, and are not forced rapidly into flower by warm wet weather in spring. Such flowers as Gloria Mundi, C. J. Backhouse, Nelsoni aurantius have been excellent. Maximus has made a splendid show, having come out early and lasted a long time; I never saw larger flowers of it. Most of the bulbs of this variety came from the south of France, where they were collected wild. By care in giving them good loam, a sunny and protected position, and frequent transplanting, these bulbs maintain their character as the finest of the old trumpet daffodils; no variety responds better to good treatment, without which it soon deteriorates. Aubrietias are a great resource to make the garden bright in April. In Surrey and other parts of the country, where the soil is warm and light, I have seen them doing well as an edging on a level border, but they will not do so here. They must grow over a fall, such as two feet or more of stone supporting the edge of a raised bed, on the upper rim of which they are planted, so as to cover the stones down to the ground, and when they reach the ground they may be allowed to spread a foot or two on the level if room can be afforded for it. Aubrietias do not root as they run, but the procumbent stalks seem to be fed by the stones or soil in which they lie, and the further the stalks get away from the roots the finer the flowers. They are now showing grand masses of purple a yard square. There are many varieties, and because these do not come true from seed, it is better to see them in flower before buying them, names being very misleading. Two of the best kinds, one rose-coloured, the other dark crimson, were sent out by Max Leichtlin a few years ago, but both revert from seed to a shabby form of the type. The brightest crimson I have came from Barr's nursery last year under the name of Fire King. A. Hendersoni and A. olympica—the last, perhaps, a true species—have large purple flowers. Another flowering late and abundantly with paler and smaller flowers is known as A. tauricola, though A. deltoidea var taurica would probably be the more correct name. The large plants get bare and shabby in three or four years, and want renewing. This is easily done by pegging down bunches of shoots a few inches from the end, and they will soon root. Those who visit nurseries in April should look out for good varieties of aubrietia and carry them off, paying for them, of course, but not caring for the name. They are probably nearly all varieties of A. deltoidea.

The shady and sheltered parts of Edge garden abound with primroses in April: nearly all the primrose tribe—some alpines of the auricula class excepted—like shade and shelter and moisture. No species is better than the old P. vulgaris. The latest development of this is the blue primrose. I have watched this improving year by year through selection in the garden of my friend, Mr. G. Wilson, at Weybridge. But the primroses at Edge, which are not blue, are also the result of many years selection from mixed colours. The qualities aimed at are size of flower, purity of colour, however pale, and absence of bunching habit, the last being difficult to maintain owing to the presence near of giant oxlips, which are too apt to cross and destroy the true "acaulis" character. In the soil of Edge these primroses last only for two or three flowering seasons, and are seldom good after division, so that continued raising from seed is going on. In summer the plants should be dressed overhead with leaf-mould and decayed manure, and again in autumn. Two other April primroses (both Himalayan) are specialities at Edge—P. denticulata and P. rosea. Both have been greatly improved by selection, and as both divide very well the best varieties can be increased without limit. P. denticulata, which includes, or rather coalesces in gardens with, the variety cashmeriana, has the fault of trying to flower in winter, or even in autumn; and as the flowers are easily destroyed by frost, and the plant makes only one flowering effort in the same season, many are liable to be lost as ornaments in this way. It is not difficult, however, to retard the flowering season by dividing and transplanting in autumn—either dividing severely by cutting the crowns through the middle in August, or more mildly by parting into single crowns in September or October. When this is done they seldom attempt to flower till April, and, with a little shelter, are seldom damaged by frost. Their favourite place at Edge is amongst the gooseberry bushes, where they share the spare ground with columbines. The colour ranges from dark violet, through pale purple, to dull white, for pure white flowers—the white of Narcissus poeticus or Trillium grandiflorum—is not to be found in this species, though it pretends to be. At least a thousand plants of Primula rosea are now in flower in the garden, in masses of fifty or a hundred together. They have to be renewed about every third year, and are troublesome plants to manage, as they require more than mere pulling to pieces and transplanting; but experience alone will teach how to grow them to perfection. The strain grown is a great advance on the type, both in colour and size of flowers. These also are liable to be damaged by sharp frosts when in flower, and like a sheltered place, but do very well under a north wall. The best variety I have is regular in its lateness, seldom coming out till the beginning of May.

Perennial candytufts (*Iberis*) are mostly at their best in April, and the varieties of I. sempervirens are amongst the best of the candytufts. True to its name of "evergreen," a variety of this species called Garrexiana makes such a dense mass of glossy green on the rockery in winter that it would be worth growing for this only; but if the plants are grown as advised for aubrietia, in falls over a steep side, they make a very showy breadth of pure white flowers, and pure white is scarce in flowers. But for a neat and lasting rock plant one or two dwarf forms of I. saxatilis are not to be surpassed. One of these, said to be from the Maritime Alps, comes into flower soon after Christmas, lasting three months in flower, and bears crowds of umbels, each no larger than a sixpence, on procumbent stems, resting on the stones. There is a second variety very similar flowering in March and April, whilst the type I. saxatilis begins in April. Many varieties of perennial iberis, mostly belonging to I. sempervirens, are offered by nurserymen under fancy names; these, like aubrietias, should be looked at in nurseries, and secured when approved. I observe this year an accidental mixture of a plant of purple aubrietia and of I. sempervirens planted side by side on a rockery, which has a pretty effect. Another pure white flower of April is Sanguinaria canadensis. It has a fleeting beauty; the whole flowering season may last through the middle fortnight of April, but each individual flower sheds in about two days. The star-like flowers with narrow petals, called in bulb catalogues "major," are inferior to the round-cupped form with broader petals. S. canadensis is of excellent habit; it thrives in either sun or shade, loam or peat, but it likes peat better and increases fast in it, spreading moderately without becoming crowded. It may be transplanted at any stage of growth, and is never shabby or untidy. The red juice, very like blood, which comes from the root when broken, has given rise to a popular superstition in Canada that it grows wild where murder has been committed. We are reminded of Virgil's story of the myrtles which grew where Polydorus had been murdered, and when pulled up dropped blood from the roots.

Pulmonarias used formerly to be much cultivated at Edge, and a collection was made of every kind to be found in nurseries. There were some with narrow leaves, some with broad leaves, some without spots, some with few spots, some of which the leaf was nearly all spot. They had flowers all blue or flowers all red, or all white, or blue and red mixed. These formed a connected series, which seemed to lead to the conclusion that as far as gardening was concerned they might all belong to one large species. The best forms are useful from their habit of early flowering, but if not in sheltered situations the frost takes the colour out of the flowers. Allied to these is a far choicer plant for the garden in April, the Virginian cowslip (*Mertensia virginica*). A hundred of these are now in flower here in masses of ten together. These want a sheltered place, a moist and rich soil, and leaving alone. They supply enough self-sown seedlings to keep up a stock, having regard to selection, for the colour and habit vary. It is, however, better not to attempt division of any of them. Orobus, or rather Lathyrus, vernus is too good to be omitted from this notice. The species likes a stiff retentive soil, in which it roots so deeply and strongly and clings so tenaciously that it is no easy matter to dig up a three-year old plant. The pods shoot the seeds to such a distance that seedlings come up several yards away. The best and most elegant of many varieties are those having very fine divisions to the leaves, almost filiform. These show the flowers better, and as the seedlings come up mixed, it is better to select them. But some of the broad-lobed leaves have the richest colour of crimson and purple, so that it is better to wait for the flowering before destroying any of the seedlings as weeds. There are some double forms, which are inferior in beauty to the single, and varieties occasionally come with the flowers pale purple or pink or white.

Amongst the many varieties of wood anemone breadths of A. Robinsoniana are, perhaps, the most attractive. It will be remembered that the roots of this species, if not occasionally separated and scattered, form such a close network that they die of strangulation, and the whole mass may disappear in a season and give rise to much speculation as to the cause. Innocent as these flowers appear above ground, they make a hard cake of tubers beneath the surface which few plants can grow through, and when I see an undergrowth of them recommended to ornament the vacant spaces of a border I attribute the advice to want of experience. The best of the varieties, I think, is a gigantic form with pure white flowers, found wild at Doneraile Park, in Ireland. Two or three bulbs due in April may be mentioned. Puschkinia scilloides is a pleasing contrast in its flowers of French grey to the masses of blue squills to which it succeeds. Ornithogalum tenuifolium produces pretty umbels of white flowers almost on the ground level, and does not degenerate like others of the genus into weediness of habit. Then by what name are we to call the late-flowering muscaris, with their conical heads of sky blue coming up in crowds where they were never sown? I bought them some years ago of a distinguished collector, who gave them at least four distinct names, and all these kinds may be there, but I fail to distinguish them. The best of them used to be called armeniacum, but E. Boissier, the botanist of Armenian plants, gives no such name; perhaps a better name is racemosum. Amongst choice alpines doing better than I ever saw them before are Androsace sarmentosa and Laggeri. The first is Himalayan, and has had a flat piece of glass laid across the projecting stones between which it grows, for it damps off with rain in winter; but with this help flower bunches are now as thick on it as they can stand. A. Laggeri, of the Pyrenees, in moderately strong and well-drained loam, grows into raised tufts like thrift, and bears small pink flowers plentifully in April.

Edge Hall, Malpas. C. WOLLEY DOD.

Average Life of Potatos.—I cannot agree with Mr. T. Davies that the Ashleaf Kidney potato is not now beaten for earliness, productiveness, and quality. In each of these points it is, to my thinking, well beaten by Duke of York and Ringleader, and I look upon the former of these as being the very finest early potato in existence. It bears at least double the crop borne by the Ashleaf, and nothing could surpass the quality, while in earliness it is at least the equal of the older variety; I myself find it earlier. Then again there is no comparison between Magnum Bonum and Syon House Prolific for weight of crop when grown under the same conditions, and I find that the latter is of first-rate quality on the sandy soil here. Other comparisons might be made, and all with advantages to the newer potatos; but comparisons are supposed to be odious, and I will only add that when one bears in mind the rise and fall of so many potatos during the past thirty years or so, the weight of evidence is all in favour of the decadence of varieties, no matter how treated.—J. C. TALLACK.

LEAVES FROM A RAMBLER'S NOTE-BOOK.

"FLOWER SHOW SKETCHES."

In the tents at Shrewsbury, the transept of the Crystal Palace at show time, and in fact at all great horticultural gatherings, not the least interesting feature is the gardeners that congregate on these occasions. So wide is the range of human nature interested directly or indirectly in the gentle art that the various grades of gardeners are marked with a distinction somewhat similar to the castes of India. It must be so in a calling having so many degrees under the same heading, and with no clear lines to mark its limit either way. Not long ago I read of an instance where a man described himself as a landscape gardener, and was highly indignant when someone addressed him as a "jobber," though in point of fact his occupation consisted of looking after the welfare of half-a-dozen villa gardens. The gardener as we find him in novels is a different character, and is generally pictured as a simple easy-going type of humanity, who addresses the heroine of the story as "missy," and in whom the habit of respectfully touching his hat to every stranger in broadcloth has grown to be quite a second nature. Your gardener of fiction may sometimes be drawn from life, but generally I think from copy or imagination. I have met with him in bothy days—in books of course—when the fire of youthful ambition burnt at its brightest, and, shuddering to think that possibly my ardent hopes might end in such a realisation, have thrown down the volume with a disgust that would not have been edifying to the author had he been present.

Still, we cannot readily determine what constitutes a gardener. There is the worthy who is the general factotum of the unpretentious establishment. He does not mind being termed "single-handed," because that points to the fact that he does all the work himself, and thereby adds to his credit. But though he fills numerous other offices, such as cowman, poultryman, perhaps groom, and cleans boots and knives, he would resent the idea of being termed an odd man, and has a way of looking down on another man who is only a labourer. He is a gardener, and is spoken of in the drawing-room as *the* gardener, and therefore has as much right, in his way of thinking, to address himself as such as Mr. So-and-So over at the castle, who walks about and gives orders to the large staff of men under his control. We do not gainsay it, as there is no law on the subject. Both are gardeners, but varying in rank. There is another point to be added. The great Napoleon once remarked that every private in the French army carried a marshal's baton in his knapsack. Something similar may be said of gardening. The various degrees are staves of the ladder. Your single-handed man is somewhere not far from the bottom, but there is plenty of room above him for climbing, and many do climb, for some who to-day are not far from the top look back with satisfaction to the time when they were equally proud of being called gardener—though only single-handed.

Big flower shows are the meeting places of all sorts and conditions of the craft, not only the working element but the patrons, who jostle with each other in the mutual endeavour to see everything. The aristocratic-looking gentleman, who busies himself in taking notes, has doubtless a garden and gardener of his own. You wonder what are the motives for which he interests himself. Pure love for gardening may prompt him, and he has decided to become the possessor of something that takes his fancy. Perhaps he is ambitious, and, feeling disappointed at seeing something which his domain does not possess, decides to have it. Or, may be, his notes are only for future reference, to be used in conversation with the gardener at home. If this be the case, he will pay special attention to the novelties, with the hope of staggering that worthy who is perhaps blessed with the gardener's happy faculty of coming out at the right end of an argument. You won't have to go very far before meeting with the fussy lady, the type of which is common at flower shows, particularly in London during the season. She is usually attended by a companion to whom she refers for the name of everything that attracts her attention, and this is straightway entered in the dainty little book that forms part of her outfit. Her moods vary. At one minute she is in raptures over some beautiful object, and at the next discontent marks her tone. She wonders "Why we can't have flowers like those," and "Why our gardener doesn't grow plants like that." She "Will talk to him when they get home," and so on. Poor gardener! the flower show is no good institution for his peace of mind, and we do not envy him his office.

Gardeners themselves are more easy to delineate. The little groups of well-dressed men who converse eagerly together are "heads" from establishments more or less well known. They are talking shop, of course, as gardeners invariably do, and perhaps the last time they met was at a show. At first it is only generalities, state of crops, condition of the weather, and so forth. Then the exhibits come in for their share of criticism or praise, and after the show individually and collectively has been disposed of, the compact of friends who perhaps were bothy mates together years ago, drift unconsciously, yet willingly, into personal matters. Though speaking as a gardener, and writing to gardeners, I think all will readily admit the interest we take in each other's doings. This interest is apparent at flower shows—the meeting place of brothers of the craft. One by one, if not all at once, each member of the group tells of his doings at home, his prospects, and his fears. 'Tis a true saying that every heart knows its own sorrow, and the skeletons in gardeners' cupboards are discussed freely at such gatherings. There is Mr. So-and-So, head gardener at some well-known establishment, who, through his office, is envied by not a few who have never been behind the scenes. But all is not gold that glitters, and though he be too wise to publish his troubles to the world, there is confidence among that little group of gardeners as they hear of his thirty men being reduced to twenty, and the place that he was justly proud of taking the form of a market garden. He knows he will find sympathy, if nothing more, and even that is cheering. Another of the group has just settled in a fresh place, and the remainder are anxious to know how he likes it; whether it fulfils his expectations, and all the rest of it. It is no half-hearted interest mind you, but real and genuine, flavoured with something that is practical in the mutual exchange of a few plants or cuttings.

From personal matters they go on to the doings of others who may only be known to them by reputation, and here you have an instance of the freemasonry of gardening. Well-known establishments are bye-words in the craft, and the names of the gardeners are invariably coupled with them till in a more narrow circle they become to be as well known as great men in the world of politics. If a gardener in such a place is about to leave, the flower show lends itself as a fit and proper place for the *pros* and *cons* of the case to be discussed. At first it is in a strictly confidential manner, that A informs B that So-and-So, of ——, is leaving.

"Leaving! you don't say so; why he's been there for years; what's the reason?"

"I hav'nt heard, but I had it on good authority that it is so. Of course it's only private yet, so you won't say anything."

"Oh no, certainly not."

B then tells what he knows confidentially to C, and so the news goes around till everybody interested knows all about it, and wonders how it is that everyone else is acquainted with the fact.

Vacant places must be filled, and the flower show is a suitable place for the discussion of likely candidates. Here there is not quite the same confidence, and A learns from B who is putting in for ——, without informing him that he himself is a candidate. This is diplomacy, which is embued in gardeners as much as in the rest of human nature. In these competitive days good gardeners are as numerous as good places are scarce. This makes men keen for the plums, and the confidential conversations among the little groups of heads mean more than idle talk.

I have said there are varied degrees of gardeners who congregate at shows, and it is easy to pick them out. There is a pair of friends who are unmistakably gardeners from the interest they take in everything, and the visit to the show is to them a red-letter day. There is a distinct country look about them, and you have not to look twice at their horny hands to know that they belong to the working section. Such men belong to the largest element of the gardening world, officiating at single-handed establishments, or where "two or three are kept." Their interest is no half-hearted one, and they think nothing of the trifles that would worry a greater man. Perhaps the flower show holiday has entailed labour out of the ordinary in the shape of being at work by daybreak, doing the watering and putting everything right. Holidays to such men are rare occurrences, and the cost is a consideration, unless the master or mistress be of a generous turn of mind. Though units in the crowd at a big show, such as they can only visit on rare occasions, these men may be lights of a gardening society somewhere, and moving spirits at the local exhibition. The holiday then is a means of education, and the mental and written notes are for further use when questioned as to what was shown at the Palace, Shrewsbury, or elsewhere. The show absorbs all interest, and rest assured that what they don't see is hardly worth looking for. Adjournment for luncheon is counted a waste of time, and instead of this hand wanders to tail pocket, which contains a package of sandwiches, thoughtfully provided for the excursion by the wife, who may have had some instructions about taking air off, or the time to syringe. If any man thoroughly appreciates a big show it is a gardener of this type, and if signs of his appreciation are wanted, follow him home among his own associates, listen to his description of the exhibition, his praise for some things and his criticism of others—vowing he could have shown better stuff himself. Ask him who was there and it is hundred to one he doesn't know. The newspaper says royalty or some other important personages were present, but he didn't see them, "didn't want particular," he went to see the show, and ask him anything about that you like. Don't think that he is discontented with his little garden after what he has seen. Not he, for he is gardener enough to know that circumstances alter cases. We may in the future have an opportunity of sketching such a gardener in his own particular sphere, but for the present forbear.

H.

Dwarf Kidney Beans.—Mr. Miller, of Ruxley Lodge Gardens, [illegible] very highly the old Mohawk bean as a capital forcer for the later part of the winter. It is odd that this variety seems somewhat to have fallen out of cultivation and from seed lists. Possibly it has had to contend with so many new rivals. Mr. Wythes has an improved Mohawk, obtained by using the old variety as one of the parents, and it has secured honours at Chiswick. I hope to grow both that and the original Mohawk this year in a trial, which will include the best stock obtainable from Reading of Canadian Wonder, Long Podded Negro, Ne Plus Ultra, three of the very best outdoor beans; Sutton's Perfection and Magnum Bonum, the best of Smythe's hybrids, and Ever-bearing, a white-seeded and wonderfully prolific variety, as I saw it fruiting in a garden at Brockham last year. Whilst there have been so many new varieties of dwarfs introduced, we have also increased our list of "climbing" dwarfs, there being now several in commerce, and some gardeners prefer to make a few sowings of these suffice, and dispense with dwarfs outdoors. Tastes differ in relation to quality and flavour of the Smooth Dwarf type of pod as compared with those of scarlet or rough runners. Some prefer one, some prefer another. Possibly Mr. Smythe's [illegible] Wonder with Scarlet Runner may prove acceptable to all tastes. [illegible] no doubt suffer very much as a rule from thick sowing; none [illegible] sown nearer in the rows than six inches to each other, and the [illegible] need intervals of twelve inches to enable the plants to have full [illegible]. The pods are badly treated also in cooking when sliced up small and [illegible] almost into pulp. They should be gathered younger, then be [illegible] and so served to table.—A. D.

DAFFODILS AT DITTON.

The daffodils are like the spring time, ever new, ever fresh, ever beautiful; each season, as their coming is heralded in February by the tiny little Narcissus minimus, we look forward with keen delight to the bold trumpet forms that will brave the winds of March, and we sigh for the exquisite elegance and beauty of Barri, Burbidgei, Leedsi, and poeticus, forms that shall continue the display through April and prolong the season well into May if the sun is not too fierce. And then as cream and yellow, gold and orange, white and silver tints appear above the waving green spear-like foliage we say—and fully believe—that never were flowers so gloriously beautiful, and there is nothing to compare with the daffodils for our gardens, woodlands, or our rooms. With each returning spring we have the same feeling with regard to these fragrant flowers, and it is a pleasure to know that every spring a larger number than formerly are enjoying the wonderful finds and productions of the firm of Messrs. Barr and Sons, of Covent Garden and Long Ditton. No other firm has done so much for the daffodil, either by spirited enterprise in collecting new species and varieties, or purchasing new seedlings and hybrids, or by patient cross fertilisation at the pleasant Long Ditton nurseries with a view to obtaining extra fine forms. This being so it is but to be expected that at Long Ditton a fine display will be on view during daffodil time, and probably not a few surprises in store.

Narcissus triandrus albus.

Narcissus bicolor Mrs. Walter] Ware.

Narcissus Johnstoni Queen of Spain.

It is easy to reach the Long Ditton Nurseries, either from Surbiton or Kingston stations (L. and S. W. R.). If you find yourself at the old town of Kingston it is but a pleasant walk past the Market Place and the King's Stone, and along the river side to Ditton. Turn down a typical Surrey lane between high hedges of white thorn and towering elm, and a short walk brings you to the celebrated nurseries. As soon as the railway arch is passed patches and breadths of colour greet the eye, and you see a big bulb farm combined with a first-rate hardy plant nursery. If Mr. P. R. Barr can spare an hour or two to escort you round then your visit will be of especial interest, for he possesses much practical knowledge.

The first move is to a spot sheltered with lattice work, where the new seedlings and hybrids and the choicest, highest priced daffodils are to be found. Here are Golden Nugget, a strong grower with a finely frilled golden trumpet of great size; this is a fine cross between Emperor and Maximus, the former being the seed parent; Apricot is something distinct in trumpet daffodils, for in its finely-formed tube is a beautiful shade of orange-tinted apricot that goes well with the white perianth. Close at hand is Lady Helen Vincent, a huge golden, large-trumpeted variety, that may be considered as a very refined Glory of Lieden, the latter variety being itself conspicuous here by reason of its bold handsome blooms. Weardale Perfection is being largely used as a parent, and up to date it has not been displaced from the position it attained four years ago as the finest of daffodils. Grace Darling, with twisted and overlapping white perianth segments that form a fine setting for the delicate pale primrose trumpet, demands attention by reason of its refinement and elegance; Victoria, the Messrs. Barrs' 1897 introduction, is a lovely bicolor with creamy-white perianth and golden trumpet, the latter finely frilled at the mouth; Victoria has a splendid constitution and grows freely. Other of the rarer trumpet daffodils that demand a word are Monarch, a magnificent yellow self, that Messrs. Barr ask the modest sum of fifteen guineas per bulb for; Mrs. Walter Ware, a beautiful bicolor, with very pure white perianth and frilled trumpet; Madame de Graaff, the largest white trumpet daffodil, having, however, a primrose tint in the tube of a newly opened flower; J. B. M. Camm, white perianth and soft chrome trumpet; and Madame Plemp, white and gold, a magnificent form with long tube. All the foregoing are more or less expensive, but there are abundance of other trumpet daffodils almost if not altogether their equals in beauty, as strong, and much cheaper. A few of the best for general cultivation, and varieties that are cultivated in thousands, tens of thousands, or hundreds of thousands, at Long Ditton, are Emperor and Empress, two popular kinds; Abcissus, a very late form, and one of the grandest for naturalising; Golden Spur, very early and rich in colour; Johnstoni Queen of Spain, one of the most elegant of daffodils, soft, yellow, with reflexing perianth segments; Maximus, the richest yellow daffodil; P. R. Barr, primrose perianth and yellow trumpet, a parent of several newer sorts; Thomas Moore, bicolor grandis, Horsfieldi, Michael Foster, princeps, cernuus and Cernuus pulcher, very early silvery-white forms; Snow King, W. P. Milner, and Wm. Goldring.

Gloria Mundi heads the incomparabilis group, or medium-crowned daffodils; it is a wondrously beautiful variety with yellow perianth and orange fringed yellow cup ; it is a strong grower, but scarce as yet. Sir Watkin is perhaps the most popular of this section, for its bold blooms stand up grandly and last a long time whether left on the plant or cut and placed in water ; Mabel Cowan, white perianth and orange-tipped cup ; Princess Mary, white ; Stella, white, with yellow cup ; Autocrat, yellow ; C. J. Backhouse, yellow and scarlet ; Frank Miles, soft yellow, twisted segments ; and Gwyther, yellow and orange, are among the best and most useful of these daffodils for all purposes. At the time of writing the Barri, Leedsi, and Burbidgei daffodils are still in fine condition, some of the forms being at their best. For elegance, especially in a cut state, they surpass the trumpet varieties, though they do not possess the substance and boldness of the latter. Nearly all are eminently suitable for naturalising, and their lightness renders them especially beautiful growing in grass. Some of the best are at the same time among the cheapest, and to see these in masses at Long Ditton is to fall in love with them on sight. Two very choice Barri forms are Sensation and Siddington ; the former has a white perianth and canary cup, the latter tipped with orange ; Siddington, introduced two years ago, has a yellow perianth, the segments being shaded with a richer tint, the cup is broad and margined with deep red ; this is a beautiful form, and usually has two flowers on one stalk. Dorothy E. Wemyss is another lovely Barri daffodil, its spreading white perianth amply setting off the canary yellow cup. Barri conspicuus is one of the best known of this group, and nothing can beat it for massing ; it lasts well in a cut state, but must be taken in the bud if its rich orange shading is to be retained as long as the flower lasts ; it lasts long in water, and is in every way a grand variety. The Leedsi varieties are sweetly pretty, and for tall vases they are eminently suitable. Among the finest varieties are Beatrice, pure white ; Fanny Mason, white, with canary yellow perianth ; Katherine Spurrell, very broad, white perianth segments, and pale canary cup ; M. Magdaline de Graaff, a lovely daffodil with pure white perianth and orange-tinted cup ; Minnie Hume, white, lemon cup, very free and fine ; and Mrs. Langtry, white, and with white cup edged with rich yellow. A peculiar Leedsi form is named Oddity, it has silvery white flowers with the centre filled with small florets.

The Burbidgei daffodils are hybrids from N. poeticus ; they flower somewhat later than the majority of daffodils, and are light and graceful. Three varieties that are first rate and make a good set are Ellen Barr, John Bain, and Falstaff ; all have white perianths, but in the former there is a citron and orange cup or crown, in the second a lemon cup, and in the third a citron cup. Little Dirk, primrose perianth and orange-tipped cup is bound to become a favourite, though the flowers are somewhat small ; Model, Vanessa, St. John's Beauty, and Agnes Barr are all beautiful. The late-flowering poeticus forms are now in full beauty at Long Ditton, and they are numbers of jonquils and Tazetta narcissi from which to make selections. Then there are the Nelsoni group, one that is not sufficiently well known, for few are more beautiful than Nelsoni major and Nelsoni aurantius, with their firm yellow and orange-tinted cups. Hoop Petticoat narciss are still in flower, and there are several beds of the charming Narcissus triandrus albus, one of the most delightful of all daffodils, and, by reason of its drooping blooms, known popularly as Angels' Tears.

Those who go to see the later daffodils will find much else to interest them at Long Ditton, for the Messrs. Barr and Sons have fine collections of tulips, and the named bedding varieties are very fine. Fritillaries of many kinds, including a fine strain of F. meleagris, are flowering, and there are some rare and beautiful Dog's Tooth violets for lovers of hardy flowers. Primulas of sorts, violas, saxifragas, species of tulips, and trilliums will provide the lover of plant genus with plenty to do for an hour or so comparing their beauty and points of interest. More commonly grown hardy plants are to be seen in abundance in plot and bed, on rocks or by the streamlet, in broad fields or even in the hedgerow, for close to the offices is a hedge where periwinkle, furze, ficaria, primroses, and all sorts of daffodils luxuriate, and make an extremely pretty picture.

VINES IN APRIL.

THE third week of April is a very busy one for vine growers having vines that were started the first week of March. While tying, beyond keeping the points away from the glass is not a necessity, it is of the utmost importance that a very rigorous system of stopping should be maintained to make the most of the vine's strength. In actual practice I find this is the third time I have attended to the vines already. Removing all doubles, or rather taking the worst out, stopping above the flower bunch, &c., all this taking much time. However, it is a most interesting operation when all looks well. At this date I find a good few sub-laterals are ready for stopping, and so there will be no waste growth by the time the vines are in flower. I generally have all growths tied permanently into position before the actual flowering period. There is no doubt that the weakest point in the vine's annual history is just before flowering. New root action can now be quickly detected by the increase of vigour, for a continuous growth is the test of good condition, and I find that this is attained best from vines which break fairly naturally.

It is most interesting to note the many peculiarities of the several varieties of grapes. By the end of this month it should be determined how many bunches are to be left on the vines, and then reduce the number showing, always leaving the strongest bunches ; growers will know the capabilities of their own vines, and so can regulate the crop accordingly. With me, in the majority of cases, ten bunches of the late varieties will weigh twenty pounds. Black Hamburgh, however, in the mid-season houses always weigh less, and so more bunches are left. The actual size of the bunches in the several varieties can only be judged by actual experience. For a three-pound bunch of Gros Colmar three inches should be its length before in flower ; but Gros Maroc is always far less in proportion to weight. Alicante, again, must be much longer than Black Hamburgh. Lastly, with Canon Hall and Muscat of Alexandria growing side by side, the former is double the size, but later on, when the grapes are ripe, there is not such a disparity in size and weight. A vine in good condition, with berries thinned just when ready, will progress steadily, and increase the size of both berries and bunches at the same time. A hot morning will necessitate careful ventilation, and application of water, &c. Avoid draughts, but admit air, and remember that healthy vines will almost always keep clean.

Bottesford Vineries, Notts. STEPHEN CASTLE, F.R.H.S.

ODONTOGLOSSUM PRINCESS CHRISTIAN.

IN a collection of the very finest odontoglossums it is extremely difficult to determine which form is the best ; the owner may set great store by a unique form that costs him a very large sum to secure, and naturally he considers this the best ; an unbiassed visitor with a knowledge of what is good among forms of O. crispum, but unaware of the prices paid for those before him, is likely to pick out quite another variety as the best. If he has a leaning toward the highly coloured and heavily blotched forms he will pick out the best of these, while another would turn to the purest white or faintly blushed forms, while yet another would give pre-eminence to a white ground form on which a moderate number of brilliant blotches are placed. We do not pretend that the variety illustrated in the present issue is the finest in the celebrated Dell collection, but it certainly is one of the very finest of the many beautiful varieties belonging to Baron Schröder. It is both robust and beautiful, for twelve handsome blooms were borne upon the spike, part of which is illustrated. Each flower measured four inches in diameter, and a glance at the portrait will show that it is what connoisseurs consider a first-rate form, as regards shape as well as colour. The ground colour is purest white save for a faint rose tinge on the sepals near the very large spots and blotches of intense blood-red. Blood-red spots are also present upon the petals, and these are well defined. The petals have fringed margins, but those of the sepals are entire though broad ; all the segments have pointed apices, but this does not mean that the flowers are stellate, as in a comparatively worthless variety of Odontoglossum crispum. So fine is O. crispum var. Princess Christian that the Orchid Committee of the R.H.S. was practically unanimous in awarding it a first-class certificate on March 22 last, when it was exhibited by Mr. Ballantine.

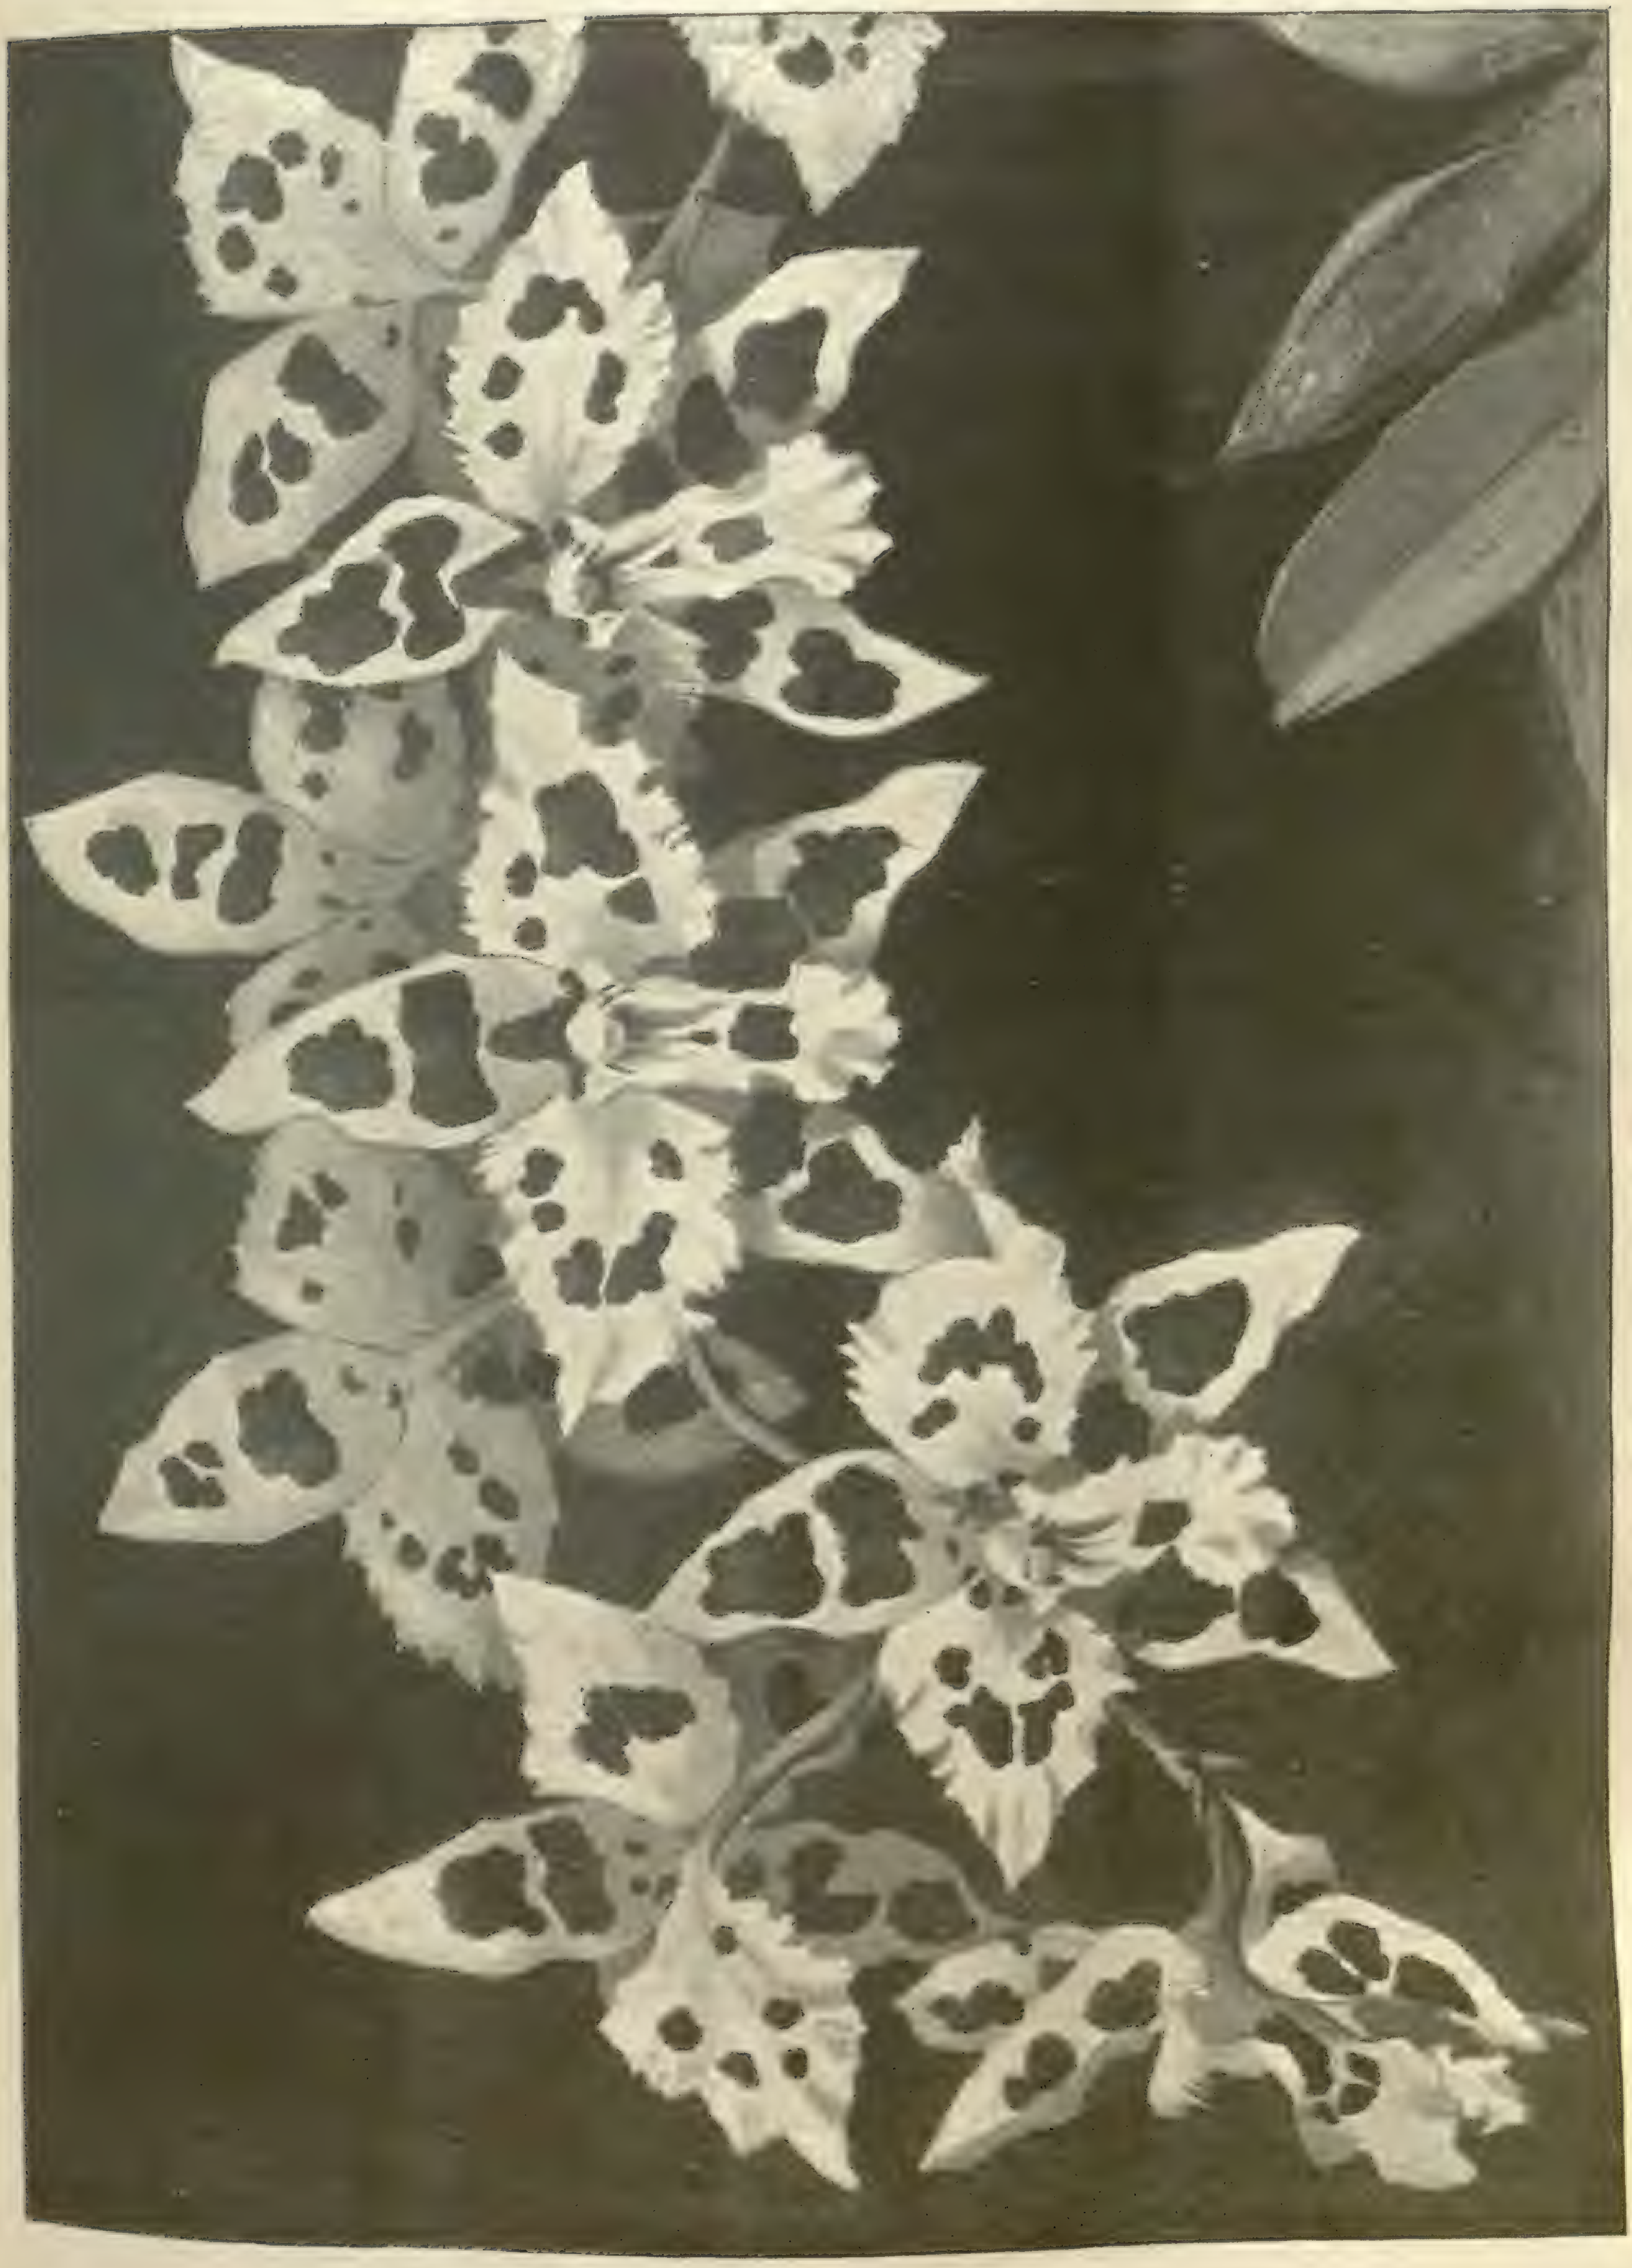
HARDY PEACH CULTURE IN NORTHUMBERLAND.

MUCH that is interesting on the subject of open-air peach culture has been of late given in these columns, and having given much attention to the peaches in the open here and elsewhere, I should like to make a few remarks in favour of growing peaches on the open walls. At nearly all the gardens in which I have been employed, peaches have been grown on the open walls successfully, and this from the extreme west of England and southern counties to this the extreme northern locality. Here we have just now (April 2) a show of bloom which I have never seen surpassed. The large flowered kinds are very beautiful ; the trees are in perfect health and vigour, and should we escape any exceptional frosts there will be a good crop of fruit. Should any proprietor desire peaches in the open where the district is favourable, there is no reason why they should not be grown without glass coping or heated walls. At least they have been grown so here the greater part of this century at least. Two years since we threw out a tree fully seventy years old, but very old trees are not profitable. We have trees thirty years old that make short growth and nearly every year yield heavy crops. The short growth is evidently the result of exhaustion of soil. The trees have not been lifted since planting, but are fed heavily with artificial manure. These have not a fair chance, and I feel quite sure that a great deal of peach-tree failure may be traced to the lack of plant food at the roots. There is not the proper vigour about old trees that have grown in the same soil more than thirty years, as the latter becomes washed and worn out, and should be removed in part at least. We find the vigour of young trees from six to fifteen years of age to be very different, especially when planted in new soil, and I would never plant any tree without the major part of the soil was new if I could help it. We usually keep a young peach tree or two trained on a south wall ready to fill up any vacancy ; we do lose a tree occasionally, but this is soon replaced with a fine young tree, and the shifting of a young tree is one of the best methods of producing good medium-sized wood, which produces fine fruit.

Assuming that we have trees in a healthy state at the roots, the next important thing is to keep them clean up to the time when the fruit is swelling and syringing can be done. I would emphasize this important point, because I know many trees come to grief at this season, and if trees are crippled by green fly and red spider, then success is impossible. The destructive power of these insects is amazing. They should be watched, and as soon as possible syringed off with luke-warm water. As prevention is better than cure, we dress the walls and trees with fairly strong insecticides before the first blooms have opened, using two ounces of soft soap to a gallon of water, or nearly a quarter of a pint of paraffin to four gallons of warm water, giving it a colouring with sulphur. These will keep down the insects during the most critical stage of growth. A large glazed sheet from say forty to fifty feet long is a splendid thing to enable fumigating to be done effectually just before the flowers open. We have similarly treated peaches indoors for many years past, and have been almost completely free from the effects of green fly. Overcropping should be avoided anywhere, especially in the north. Trees should be [illegible] disbudded, doing] the work gradually ; we rarely do much disbudding on outside trees until May, as plenty of growth seems to give vigour, and one has then plenty of shoots to choose from.

We have never unnailed the trees here to remove the growths from the walls, and do not believe we have lost a crop through being early. If we have had a good season to ripen the wood the previous year we [illegible] have a full crop of fruit ; if a bad season, wet and sunless, then the trees fail to bloom properly. We obtain a crop of peaches on the [illegible] heated wall, but shaded with No. 3 fruit-protecting material, as [illegible] as we grow a crop of apples. This protecting material is [illegible] removed from the time it is laid on the walls until about May 13. We have frequently seen visitors from southern counties surprised to see peaches grown in such quantities on open walls so far north. Naturally we do not grow the earliest kinds ; Royal George and Dymond are two of the most reliable varieties for us.

Alnwick Castle Gardens. GEORGE HA[illegible]



ODONTOGLOSSUM CRISPUM PRINCESS CHRISTIAN.

THE FRENCH LILAC TRADE.

THE French lilac trade is not only a very important branch of industry, but its quaint history is equally as significant; thus, whenever the yield is rich, it truly represents quite a little fortune for the inhabitants of the village of Frette, which is situated sixteen miles from Paris. The village itself is in the midst of a veritable lilac forest, having an area of some 1,600 acres of barren, chalky soil, which during the season of three weeks will produce nothing else. The branches are cut, tied together, as if so many sheaves of corn, and transported during night time to Paris. On their arrival at the Halles Centrales, the bundles are duly untied and sprinkled over with fresh water. The village of Frette, thus sells yearly £2,920 worth of the choicest lilac; the five hundred inhabitants either own part, or rent plots of the ground from the State or the Commune. When the lilac season comes to an end, the Frettois, which is the name given to the inhabitants, fall back on hiring themselves out as farm servants, others prefer living on the produce of their river fishing; while during the winter months their principal industry consists of making mats, brooms, and beehives. The village of Frette, though abounding with lovely lilac, is the poorest and the least looked after, as well as the most neglected in every sense of the word, within the department of the Seine-et-Oise. It is sufficient for the peasants of that popular village—who, as already remarked, make their living mostly by lilac-growing, and many make a few thousand francs by the industry—to plant one single stem of lilac in an almost barren field, where nothing else can be cultivated, to possess within a short time a most productive and flourishing shrub. Curious to remark, when the inhabitants are asked to sell part of their ground, they certainly do not keep their buyers waiting long for a negative answer, owing to their exaggerated pretensions about the price of their plantations.

While on a visit to Frette recently, the writer was told of an amusing anecdote which fully corroborates the truth concerning the refusal on the part of the Frettois to reasonably sell an inch of their barren soil. Thus, a cobbler some years ago, who carried on his trade at Frette, and who was a large land proprietor, received an unexpected visit from a Paris land surveyor, the latter having come down specially on behalf of an intimate friend of his, with a view of purchasing a small allotment which belonged to the shoemaker. The cobbler was offered two hundred and fifty francs, or £10, cash down, which implied a price of half a franc, or fivepence per yard, which was considered a very reasonable offer on the part of the surveyor, especially as it was nearly barren soil. The shoemaker, however, most contemptuously refused such a proposal, and exclaimed in the greatest astonishment possible: "What, two hundred and fifty francs! You seem to forget, sir," he continued indignantly, "that without the least trouble my few perches of land represent an annual yield of lilac to me of one hundred and fifty francs alone; now the latter, in twenty years, would represent a sum of three thousand francs [or £120;] such is the price you will have to pay, if you want to buy my insignificant plot of land." Needless to add, the purchase was not effected. This instance clearly illustrates the value set upon their land by Frettois in general.

The whole surroundings of Frette being equally lilac-producing thefts are much on the increase. The Frettois accuse—and not without cause—cyclists of being the most daring thieves, the more so, as there seems to be no bound to their audacious helpings of the flowery shrub. Lilac-thieving is not limited to the village of Frette and its environs, but the suburbs of Paris equally suffer from similar acts of dishonesty. "Guards" are posted at various distances at Frette during the collecting of the shrub, to keep off thieves; but, notwithstanding the most careful watching, cyclists manage to pluck away as audaciously as ever, trusting to the speed of their machines to carry them safely away. The majority, on approaching a shrubbery dismount, creep on their hands and knees to the coveted spot, and cut away at the branches, while some comrades keep watch; at the least signal of danger, they regain their bicycle, thus firmly believing in the maxim that:

> "He who steals and runs away
> Will live to 'rob' another another day."

Generally speaking, the French lilac industry has made great progress of late years; much of this is largely due to the fact that Parisians have taken more kindly to the plant; it is not too much to say that actually lilac is *par excellence* the most favourite flower of Parisians of both sexes. Of course this craze has greatly benefited culture, hence the successful harvests throughout France during recent years. There is an incessant demand for lilac in Paris during the season, especially by housewives, who are to be seen daily laden with the two varieties of lilac; no time is allowed for the flower to fade, as extra quantities are purchased, thus a constant fresh supply replenishes vases in every home, whether poor or rich. The outsides of Parisian railway stations offer a pleasing sight during the whole of the lilac season, where the courtyard is usually filled by roughs of both sexes offering branches of lilac at moderate prices.

So extensive have been the thefts in and around the public parks of Paris and gardens, that a severe censure has been imposed. Thus, the devastation of lilac trees in the Bois de Boulogne, having assumed a terrible increase, the park-keepers at each gate request every person carrying lilac to give the same up, under the penalty of being prosecuted for thieving: too often large handfuls represent a day's collection. Notwithstanding these strict measures, the keepers themselves confess that vigilance and watching prove vain, as far as checking the wholesale breaking of lilac branches and trees is concerned by *promeneurs*, who out of spite not only break twigs, but trample flower-beds down, besides plucking flowers which they store away in their pockets and handbags till safely out of the park gates. It is a well-known fact that the passion of Parisians for all kinds of flowers is irresistible. No French family would ever think of returning home after a Sunday's outing in the country without some horticultural or botanical *souvenir*. Again, the better to check this growing "evil," custom house officers, who are stationed at all Parisian railway termini, call upon passengers carrying flowers to produce a *laisser-passer*; this ticket or pass should by right be signed by the owner of suburban gardens with whom the travellers have been spending the day, and setting forth that the said flowers are not only the outputs of their own gardens, but that the flowers [illegible] were cut with their consent. This check though well intended, is none the less insufficient, for what control is there to prevent the said passengers from increasing their bunches from other people's gardens on their way to the station? Any persons unable to produce the required *laisser-passer* are compelled to give up their bouquets to the officials; no fine is inflicted, as that would entail too much trouble to trace the origin of the supposed theft, and of the owner's identity; all that is done is merely to confiscate the suspected flowers and shrubs, which are ultimately destroyed by the custom house officials.

Though cyclists are looked upon with an evil eye they are not the only sinners, for another class of forgetters of the Decalogue—wealthy ladies—are equally as guilty; thus it is a common practice among rich Parisian ladies who drive about in their carriages to drive to neighbour-woods and favourite spots well stocked with lilac and other flowers. The coachmen are instructed beforehand to keep a good look out, and not to forget to stop when passing a flourishing shrubbery, to mount the box, cut away at the branches, and when a certain quantity has been gathered the sprays are secreted carefully under the seat, and the occupants of the carriage return to Paris smiling with innocence.

EDWARD CONNER.

THE NARCISSUS CROP.

WHEN the first blooms of such common types of narcissi as the English Lent Lily and Telamonius plenus (double daffodil) commenced to open their blossoms, I made up my mind for a poor season. Speaking generally, my fear has not been realised, for up to the present time it has been, in this garden, a really good one. We grow some thousands of bulbs in various places, such as rose borders, pæony beds, amongst herbaceous plants, and in the Michaelmas daisy border, as well as about two acres of wild garden on grass. We never have had so good a display as during the past fortnight. Not only is the foliage robust and healthy, but the individual blooms are of really good quality. At the time when the varieties alluded to were opening their first flowers, a contemporary alluded to the promise of a poor crop, and gave as a reason that the excessive rain and cold weather experienced in March of last year was no doubt the cause. This coincided with my own ideas, as here we experienced more than an average rainfall at the time. No doubt this is all against the due and necessary growth and maturation of the bulbs for the next season's flower crop. By the end of April 13½ inches of rain had fallen in this neighbourhood, which in a yearly average of 30 inches is excessive. I noticed, too, that where the bulbs were growing in less exposed situations, such as near trees, they produced still fewer blooms than those of the same variety quite in the open. This was still further proof that the weather of the previous season was partly responsible for the semi-failure. Less rain having fallen during the two succeeding months, the later flowering kinds were not so adversely affected.

The cultivation of narcissi has, of course, a beneficial effect upon the results, as in all other flower crops. Here there is no comparison in the luxuriance of the foliage and flower of N. Horsefieldi, for example, growing on grass, as compared to others established in the rich soil of the rose and herbaceous borders. Thousands of bulbs of varieties like Ornatus and Poeticus, growing amongst fruit trees, have not the same appearance of robustness, owing to the somewhat poor nature of the soil, as compared with the more generous treatment accorded the bulbs in other sites. To grow narcissi in the best possible condition annually there must be no haphazard method of treatment allotted to the [illegible]. Especially fine are the blooms this season of varieties like Sir Watkin, Emperor, Golden Spur, Princeps, Barri conspicuus, Odorus rugulosus, Mrs. Thompson, Figaro, Queen Bess, Nelsoni major, Albicans, Obvallaris, Maximus, and Telamonius plenus—the last named grown under glass in boxes of rich soil. It is not in every garden where space can be found to grow numbers of the various narcissi in beds by themselves. I adopt the plan above alluded to of filling the space between the regular occupants of the pæony garden, rose borders, as well as among the many herbaceous plants in a wide border, and amongst the Michaelmas daisies. In all these positions we meet with much success. The flowers are extremely useful for cutting, while, when growing, they serve to brighten up an otherwise dull part of the garden during the latter part of March and throughout April.

E. MOLYNEUX.

Swanmore Park Gardens.

Strawberry Royal Sovereign.—I, like Mr. Wythes, have another good word to say for this strawberry, especially for forcing. I liked it from the first when Mr. Laxton sent me a few plants for trial. From these plants I [illegible] April fruits weighing 1½ ounces. For years I have pinned my faith to [illegible] Hericart de Thury for the earliest first supplies, having seen this [illegible] so well cultivated at Heckfield by the late Mr. Wildsmith. The experience so recently gained of Royal Sovereign, under adverse conditions [illegible] imperative that the latter must entirely take the place of the older variety. [illegible] side by side in one of the worst places imaginable—under the deep [illegible] there is at the present time a great contrast in the two varieties in favour of the newest. Even obtaining so little sun as the plants do under such [illegible] circumstances, the fruit of Royal Sovereign has coloured remarkably well.—[illegible]

WORK FOR THE WEEK.

COOL ORCHIDS.

In the cool houses the plants are now starting to grow freely. The spring months suit the occupants remarkably, but the occasional drying east winds are not beneficial, so ventilation should be moderately afforded when they exist, for a dry atmosphere may check the plants and it undoubtedly increases the insect pests. The plants should be examined carefully, and any aphis that have settled on the flower spikes should be removed at once, for if left until the flowers begin to open they cripple them to a large extent. Odontoglossum crispum will be commencing to present a gay appearance, as will O. Pescatorei, O. polyxanthum, O. hystrix, O. luteo-purpureum, &c. These plants carry their spikes in perfection for several weeks. It is, however, a bad practice to let these remain long on the plants, as it naturally causes the bulbs to shrivel. There are some examples that are making new growths and carrying flower spikes at the same time; in such cases the spikes should be cut off as soon as the flowers have expanded, for if allowed to remain the young growths will be weakened considerably. Odontoglossum Oerstedi with its dainty little flowers forms one of the most charming objects in the cool house at the present time; it is a native of Costa Rica, being found there at elevations of 7,000 to 9,000 feet. When commencing to grow this species should be watered very sparingly until root action begins, and even then they should not receive overdoses of water; during the winter months only sufficient water will be needed to prevent shrivelling.

Any plants that have been wintered in the intermediate house may now be removed to their growing quarters, and the warmest end of the odontoglossum house will be found a suitable place for the following during the next six months: Odontoglossum Krameri, O. nævium, O. cirrhosum, Miltonia vexillaria, Lælia harpophylla, Dendrobium infundibulum, D. Jamesianum, Masdevallla Schlimi, and all the chimæra section may be removed, and also M. tovarensis that has become re-established. Masdevallias should receive a good supply of water during hot, dry weather, and it will be beneficial to syringe the foliage of all plants of members of the chimæra section on fine mornings; the other species mentioned should be kept decidedly moist at all times, and as all are liable to become attacked by yellow thrips, a careful watch should be kept, as if allowed to become established the grower will find much difficulty in ridding the plants of the pest. Barkerias are now commencing to grow, and new roots will proceed in due course from the base of the young growths; these plants are best grown in baskets, or on flat blocks of wood, with sphagnum moss about the roots, and suspended from the roof near the glass; a position should be found for them at one end of the cool house, where they may be exposed to full sunshine, and given abundance of water during the growing season. Syringe the plants at least twice or three times daily, and should any become too tall they should be shortened by cutting off a portion of the base, then placing the plants in baskets or on blocks of wood. If baskets are used make the plants secure by tying the stems to the wires, three parts filling the receptacle with crocks and charcoal, and surfacing with moss.

One of the principal operations necessary among orchids making growth is watering, and it takes up a great deal of time now; rain water should always be used whenever obtainable, particularly for syringing, so means should always be taken to supply tanks large enough for a good store in case of long spells of dry weather; the water should be warmed to the degree allowed for the night temperature of the house. I always make it a practice to commence watering as soon as the thermometer indicates the proper temperature of the houses, affording a thorough soaking to all those plants that require it; plants that are grown on blocks of wood and in shallow pans should be examined daily. Small slugs and snails are very troublesome at the present time, and unless kept under will destroy the young roots as fast as they are put forth, which, of course, very much weakens the plants.—E. SHILL, *New Hall Hey Gardens*.

STOVE PLANTS.

WITH the increase of temperature, owing to the progress of the season, insect pests will increase rapidly, and unless unremitting attention is paid to their destruction they will sadly disfigure the plants and cripple growth, for, be it remembered, these pests are pure parasites, and draw their sustenance from the elaborated sap of the plant, thus depriving the host of that matter which otherwise would go to its further development. In this department the most troublesome pests are thrips, mealy bug, and various kinds of scale; to destroy the former, fumigating two or three nights in succession with XL All fumigating compound will effectually destroy it. Regarding the two latter my experience is that to eradicate them is impossible, therefore to keep them in proper subjugation a fortnight-syringing of the infested plants with one or other of the best-known insecticides is the most efficacious plan to follow. Where blinds are not provided for shading, the permanent shading, such as summer cloud, should now be applied; a bright day should be chosen; the house not damped down, and a little air to be kept on until the shading has quite set; if these precautions are not taken the moisture will condense upon the inner surface of the glass, percolate through the laps, and, in running down the outer surface, wash off the application. To obviate the necessity of running frequently to the fire to warm the summer cloud, use a carpenter's glue-pot, or something similar, so that the vessel containing the paint can be immersed in hot water; thus all that is necessary is to change the water when it becomes cooled, and much time will be saved.

Allamandas, stephanotis, and dipladenias, which are being grown in pots and trained upon hollow trellises for the purpose of exhibiting, or being used as specimens in large conservatories when in flower, should have their shoots trained up strings until they have attained sufficient length, and set the flowers, when the strings can be cut and withdrawn, and the shoots tied down carefully to the trellis. Pot up successional batches of gloxinias, tydæas, and achimenes; these require to be drawn near the glass, to have all the light possible, taking care, of course, that they do not become scorched; if grown in a dense shade the flowers are useless for cutting, and the plants will not bear removal for room or conservatory decoration. All stove plants are now growing freely, and, with the exception of those recently repotted, will be benefited by the occasional application of a good fertiliser, but in using this do not apply too much at once, and allow two or three weeks between the applications. If liquid manure is used be careful not to use that which is thick and muddy, or it will render the soil sour.

The end of April is a suitable time to propagate the various varieties of winter flowering begonias, such as B. corallina, B. President Carnot, B. heraclifolia nigricans, B. manicata, B. hydrocoty lifolia, B. Gloire de Sceaux, and B. nitida, may be propagated singly in small pots; such as B. insignis, B. Knowsleyana, B. parviflora, B. hybrida multiflora, and B. fuchsioides may be propagated three or four in a three-inch pot, to be potted off singly when rooted. Loam, leaf-soil, and sand will be the most suitable compost; and if the propagating-case is over-stocked they may be rooted quite successfully in the body of the house, if the atmosphere is kept moist and they are shaded from the sun. The variety Gloire de Lorraine, which is admittedly one of the most beautiful of the dwarf section, is by far the most difficult to work up a stock of, it being difficult to procure shoots free from flower for propagating purposes, and my experience is that it is useless to insert as cuttings those shoots showing flower. Rooted cuttings of Strobilanthus Dyeranus should be potted on into five or six inch pots, potting them firmly and standing in shade—if the sun reaches them they will lose their colour directly. In potting on young plants of Phrynum variegatum and Dracæna Sanderiana pot three young plants of each into a five-inch pot, for if potted singly they have rather a weedy appearance; this dracæna will be found to thrive better on a smaller supply of water than the rest of the family. Close the stove early in the afternoon to raise the temperature up to 90 degrees, at the same time affording a good syringing, and if the house is a lean-to, and dries up quickly, give another syringing before five o'clock.—J. TUNNINGTON, *Ripley Castle Gardens, Yorks.*

FRUITS UNDER GLASS.

MELONS growing on trellises require some support for their fruits, and this should be given in good time to relieve the vines from their great weight. Where the trellises are rigid, the simplest support is formed with strips of matting, either crossed under the fruits or tied to a ring of the same material, in which the fruits can rest without being in any way pinched or prevented from swelling to a good shape. In other cases it is better to join rests of thin squares of wood with a string or wire for attachment to the trellis; there should be a hole with smooth sides in which the eye of the fruit can rest, without fear of its being kept wet. Woodlice are frequently a great nuisance to melons in their earlier stages, and will, if not kept down, either destroy the fruits or render then unsightly. Traps for these insects may be formed of hollowed halves of potatos, which should be laid cut side downwards, and examined frequently; pots of dry moss, too, are good for the same purpose. The best and safest way of clearing out woodlice is to pour boiling water round the sides of the beds and into all crevices to be found in the house, taking care, of course, that the melon roots are not so watered. One or two such applications will do wonders. Afford liberal doses of liquid manure to plants on which the fruits are swelling, as such have much work to do in a short time, and require support of this kind. When netting is completed, return to the application of clear water, and from this time until the fruits are ripe the plants will require less water than they have hitherto needed. During the summer and early autumn months, it is often necessary to depend on frame cultivation of melons, and this is an easy matter, provided constant attention is paid to the linings, and fluctuations of bottom heat avoided. Frames may be planted now at any time, and the general conditions are such as were stated a few weeks ago, the great thing to remember being to always plant thrifty young plants, and not those that are pot-bound. Seeds should be sown for each frame, rather more than three months before the fruit is required. Careful ventilation and early closing to secure the safest maximum of sun heat are important factors in melon culture, and must not be neglected, also plant in soil made very firm. If the bed on hillocks of soil be made along the centre of the frame, pinch out the tips of the plants when they have made three leaves, and form leaders of the two strongest breaks, taking one towards the front and the other towards the back of the frame; take out the points of these leads before they reach the sides, and fruit the plants from the first set of laterals, if possible, so that the frames may not be crowded with foliage.

Work in peach houses will now be plentiful. In the early house the fruits will need exposure to full sunlight by elevating them above the foliage, or by tying the latter back clear of them, never by cutting it off. Syringe freely to keep down spider, and so retain the leaves in perfect condition, see that the borders are well supplied with water, for dryness at the roots must be avoided if good fruits are wanted. Continue disbudding and tying-in shoots, which are necessary items in management. When in doubt as to the removal or otherwise of a shoot, the former is generally the safest course, unless it be the leading shoot above the fruit, when it must be left, but never forget that the general tendency is to leave far too much wood in peach and nectarine trees, and act accordingly all through the season for disbudding. The latest vines will now be getting forward, and a caution as to scalding of berries and leaves may be useful. Lady Downes, one of the most useful grapes for keeping, is especially liable to scald, and houses containing it and all such varieties should invariably have some little ventilation left on at night after the berries have set, and more should be added quite early in the morning. It may, in the case of houses with bad glass, be necessary to shade the roof slightly, the best method being to apply a very thin coating of summer cloud, which must be put on while warm, and with the glass in a thoroughly clean and dry state.—J. C. TALLACK, *Livermere Park Gardens.*

WHITEWASHING PEACH TREES.

A GOOD many British fruit growers will be able to verify the experience of the Columbia Experimental Station given in a recent issue. It is a good many years since some of us discovered that common limewash was one of the cheapest insecticides—cleansing bark, branches, and twigs, and rendering the crevices in wood and bark ungenial to insects of all sorts, sizes, and stages of evolution. It proves not only a powerful cleansing agent, cheap and harmless, but also a protecting force of great potency; and it was also early discovered that the whitewash saved the trees, or rather their blossoms and embryo fruits, through making and keeping them cool. In early life I saw experiments made on some walls, differing only in colours. These were black, yellow, red, blue, white. One fact that came out clear from much doubt and obscurity was the retarding of the blossom of peaches, pears, plums, by from a fortnight to three weeks by whitening. Cultivators hardly need to be told that such retarding in early spring often meant the gain or saving of a crop. The Columbia and Missouri experiments seem to have bettered our practice of whitewashing, inasmuch as it was repeated four times; this, of course, added to their whiteness and consequent coolness and resulting lateness. The salt could have little or no effect in retarding growth, and a little flour added to the skim-milk made the British whitewash stick on from November to April. There is, however, no objection to repeating the whitewash provided it is not used when the trees are in bloom.

In the last week of March a fine peach tree on the open wall so far north as Perth, N.B., was in full blossom; had it been whitewashed it could hardly have been so forward until the middle of April, being thus whitewashed into greater safety. Its experienced grower, however, looks for sure cropping by letting his trees alone. If, he says, growers would only let one peach tree alone and note results there would be a speedy end of all forms and methods of covering and coddling peaches in the open air. Should your readers care to hear more of the size, age, and doings of this fine peach tree at Perth, I will supply these another day. D. T. F.

THE BEST GUIDE to the garden for the whole year is the "Gardening Year Book," containing practical articles on the cultivation of Flowers, Fruit, Vegetables, &c. Price 1s, "Gardeners Magazine" Office, 4, Ave Maria Lane, London.—[ADVT.]

PRACTICAL SUGGESTIONS TO FRUIT GROWERS.

THE following suggestions in the annual report of the Secretary for Agriculture, Nova Scotia, are especially deserving the attention of fruit growers in the United Kingdom :—

I. Upon Insects.

Practically all the applications which are made to destroy insects are designed to act in one of two ways. The substance may be destined to enter the digestive system of the insect and thus cause death, just as many poisons cause death when taken into the stomachs of the higher animals. This method is by far the cheapest, and when possible it is advisable to make use of it.

The second method does not consist in putting poison on the food of the insect, but the material is put directly upon the insect itself. It then causes death either by stopping up the breathing pores, or it penetrates the outer coverings and so enters the body directly. This method cannot be used with success against all insects, as some have very tough and dense coverings which are not readily penetrated by any material that we can use for the purpose. Beetles, for example, can scarcely be dectroyed in this manner. But all soft-bodied insects, such as aphides, and caterpillars, yield readily to the treatment if sufficient material comes in contact with their bodies.

This method of killing insects by means of substance which causes death merely by penetrating the creature's body is rather expensive, and it is resorted to only when the pest cannot be treated by poisoning its food. It thus comes that most grubs and caterpillars are destroyed by means of poisons which are eaten, though they yield to the other treatment equally well.

The food of many insects, however, cannot be poisoned since they feed upon the juice of plants and do not eat the external coverings. It is fortunate that most of these insects have soft bodies, so that they yield readily to treatment if the poison comes in contact with them. Their mouth parts are formed for penetrating the external coverings of plants to a depth sufficient to reach the sap ; just as the mosquitoes' bills are in the habit of penetrating human kind. All aphides belong to this class, as well as the true bugs, these having mouth parts which are adapted to suck, but not chew. The utter uselessness of covering a plant with poisons to protect it from these pests will readily be seen. The insect's beak will penetrate this poisonous layer and it will take no food until the beak has passed the limit of the poison and is deeply buried in the tissues of the plant.

From the above it will be seen that—

(*a*) To destroy chewing insects, such as the caterpillars of the winter moth, poison must be evenly distributed over those parts upon which the insects feed, and this may in some cases be done even before the insect is present, or is visible. Only those poisons which cause death after eaten should be used.

(*b*) To destroy sucking insects, such as plant lice, the materials must be distributed upon the insects as evenly as possible, and it is useless to make any application before the insect has appeared. Only those poisons which kill by coming in contact with the insect's body should be used.

First determine what kind of a pest it is that needs treatment, then select the proper material.

II. Upon Fungi.

Among the fungi we find many enemies. It is difficult to tell just what a fungus is, but some of the principal characteristics may be mentioned. A fungus is a plant ; but, unlike flowering plants, it possesses no chlorophyll. Chlorophyll is the green-coloured protoplasm found in flowering plants, and it is the only substance we know through which plants change crude food to nutritive material. We must conclude, therefore, that fungi do not prepare their own food, but feed upon organic matter, which is already adapted to their wants. They possess no leaves, flowers, or seeds. That part of any fungus which is of most interest to the horticulturist is composed of long, fine threads, are known as hyphae, and collectively they form the mycellium or vegetative portion of the fungus. The mycelium corresponds to the roots and stems of flowering plants.

Spores, which are organs performing the same office as the seeds of flowering plants, are produced by this mycelium either directly, or upon branches (sometimes called sporophores) which are thrown out. These sporophores cause the white downy appearance seen upon grape leaves affected with the downy mildew. A spore, strictly speaking, is not a seed, for a seed contains a young plant, while a spore does not, being usually composed of only one cell. If a spore finds the proper conditions of heat and moisture it will germinate and send out a fine filament, which, if nourished, eventually produces a plant like the original.

Most fungi in the north produce two kind of spores, known as the summer and winter spores. The summer spores are usually borne upon the exterior of the host-plant, or the plant on which the fungus grows. These spores ripen quickly and propagate the fungus rapidly. But if they do not germinate soon after ripening they lose their vitality. The winter spores are usually produced within the tissues of the host plant, commonly in the leaves and fruit. They are the spores which live through the winter ; but in the spring, under favourable circumstances, they germinate, and thus the fungus is again developed. Fungi may be divided into two general classes : those growing upon dead and decaying matter, or saprophytes ; those feeding upon living tissues, or parasites. By far the larger portion possessing interest to the horticulturist belong to the latter class, for in this are included the fungi which do so much injury to cultivated plants.

Yet all parasitic fungi do not attack the host-plant in the same manner. Some immediately penetrate into the interior tissue, and there they flourish, being well protected from outer influences by the exterior covering of the plant. The fungi causing all the more serious diseases develop in this manner and, in fact, the vast majority of plant diseases are caused by such organisms. There are others, however, in which the body of the fungus is almost entirely upon the surface of the host plant, only a comparatively small number of threads penetrating the tissues in order to obtain nourishment. These parasites can be rubbed off, and unless the attack has been very severe, the green, healthy tissue will be seen underneath. This class may for convenience be termed "surface fungi" ; to distinguish them from those which grow within the host-plant ; it is represented by the common powdery mildew of the grape, one mildew of the gooseberry, one of the strawberry, and a few others.

The life histories of the various fungi must form the basis for any methods of treatment which may be adopted. During certain stages of their existence parasitic fungi may be checked quite easily, and at such times the remedies should be applied. It is evident that when a fungus has once become established inside the host-plant it cannot be reached without destroying the tissue of the host in the affected places, which is by no means desirable. The fungus must be destroyed before it enters the host ; in other words, the spores must be killed as soon as they germinate, or better, they must not be allowed to germinate. All applications must be preventive, not curative, since a cure is practically impossible, when the fungus is once established, unless it grows upon the surface of the host.

The line of treatment indicated is this : To cover the stems and foliage of the cultivated plant with some substance that will destroy the spores which may be present, as soon as they germinate, or with one that will have the power of preventing this germination. If that is done the plant will remain healthy, so far as fungi are concerned ; otherwise it will not, unless, indeed, no fungus attacks it. several substances which destroy these spores, as well as the surface fungi have already been found. They are easily applied, safe, and effective, and any grower, who suffers his fruit to be ruined by these parasites is, as a rule, deserving of his loss, for means of destroying the pests are at his command. It is largely the grower's fault if his apples are scabby, and if his potatos rot in the field. Spraying is no longer an experiment, it is a necessity ; and those who recognise this fact are the ones who are reaping the rewards.

Spraying Machinery.

The best spray nozzle, so far as efficiency, simplicity, and cheapness are concerned, is the end of a hose and a man's thumb. Unfortunately, the thumb gets sore and tired, and operations must be suspended to wait for repairs. It is the nearest approach to the ideal nozzle yet devised, if it were only more practicable. It will do all that a good nozzle should do. It throws a fine, mist-like spray, one that will "float in the air like fog." or the particles of water may instantly be made coarser, and the water thus carried to a greater distance ; or still coarser and the water leaves the hose in the form of a solid stream. These changes all take place instantly (after a little practice), and it makes no difference whether the parts to be sprayed are a few inches or many feet away. This nozzle never clogs, but is cleaned automatically, and as quickly as the character of spray is varied. In fact it possesses all the desirable qualities of a spray nozzle, except durability, and for this we must turn to the metals for aid.

All operators do not desire the same kind of spray even for the same kind of work. It is commonly said that the best spray is one which most nearly resembles a fog. This is true so far as the spray is concerned, but the trouble comes in applying it. A fine spray cannot be applied so advantageously us a coarser one, nor can it be applied so rapidly for the reason that the finer the spray the less liquid is thrown, and the smaller the area treated. Whenever the wind blows, a fog-like spray will go wherever the wind carries it, and not where the operator directs it. Sometimes this will be an advantage. It is especially so when the wind is blowing in the right direction. Yet when the other side of the tree is being treated the wind will come from the wrong direction, and much of the material is blown where it is not wanted. In addition to this, the work is more slowly performed, and whether it is more thoroughly done than when a coarser spray is well used is still open to doubt. After having tried both kinds of sprays, it appears to the writer that if the parts to be treated are close by, a fine spray is to be preferred, as then there is less waste and an even application may be made. If the parts to be treated are more removed, being situated from ten to twenty-five feet away, a coarser spray is wanted—the more distant the object, the coarser the spray. The work can thus be done much more rapidly, just as effectually (with the exception of some waste), and much more satisfactorily, than by the use of a fine spray. In case a fine spray is used, it is necessary to have a pole to carry the nozzle to the different parts of the tree, and this is as tedious as it is unpleasant. When a coarser spray is made, there is generally formed enough of the finer spray to float in the air and protect parts which are not directly reached by the operator.

The finest sprays are produced by the eddy-chamber nozzles, and by those in which two streams of water strike each other at an angle. With such nozzles spray can be made as fine as desired, the size of the outlet orifice being the main controlling factor. For long distance work, when the liquid is to be carried ten feet or more, the best spray is formed when the fluid is forced through two flat parellel metal surfaces. The greater the pressure, the greater will be the amount of fine spray and the farther will it be thrown. Although the ideal nozzle has not yet been made in metal, some of the forms now sold are approaching perfection.

All good spray machinery is expensive, and only careless operators will neglect the ordinary methods of preserving it as long as possible. When the pump has been used in applying any of the preparations with the exception of clear water, it should be cleaned. No insecticide or fungicide should be allowed to stand within the pump, but clear water should be pumped through it before it is put away. It is well to oil all the working parts occasionally, as a little oil at times may prevent the metal from being cut, and the pump will be thus preserved much longer than otherwise. Nozzles are also benefited by the same treatment. Oil can scarcely be used too freely on the inside of such apparatus, and an occasional coat of paint on the outside will assist materially in protecting the metal. The careless man pays dearly for his neglect.

Spraying Fruit Trees.

The following suggestions on the spraying of fruit trees are from the pen of Professor E. E. Faville, formerly of the Novia Scotia School of Horticulture, Wolfville :—

No feature in fruit growing should be more thoroughly understood than that of spraying properly with insecticides and fungicides, for by judicious work the crop is protected, it becomes cleaner, markets at a higher price, and often times the crop is saved, especially during the favourable seasons for insects and fungous growths. To spray in season should be one of the chief aims of the operator. We will consider the following remedies for trees affected by [illegible] which are of two kinds : first, those that chew their food ; second, those that [illegible] the juices. The former may be destroyed by poison eaten with food. For [illegible] moth, bud moth, cankerworm, and insects of that character, use the following mixture : 1 lb. Paris green, 200 gallons water. Stir the mixture while spraying, as the greater portion of the poison does not go into solution, thus avoiding [illegible] injury to the leaves. This strength is suited to nearly all foliage. London purple [illegible] may be used instead of Paris green, but it is more caustic, and about twice [illegible] weight of lime should be added. Trees affected with the bark louse or tree [illegible] should be washed early in the season with the alkaline wash made as follows : Soft soap, washing soda, made to the consistency of paint, applied with a [illegible] the tree. In May or early June, when the bark louse is hatching, spray [illegible] kerosene emulsion made as follows : 2 gals. kerosene, 1 gal. water, [illegible] Dissolve the soap in the water by boiling, add kerosene, and churn violently [illegible] mixed. This forms a stock solution, to every one part of which add nine [illegible] water and apply as a spray. This solution is used for all kinds of sucking [illegible] as cabbage worm, scale insects, currant worms, &c. For fungous diseases [illegible] with the Bordeaux mixture, introducing Paris green, thus making the mixture [illegible] combined insecticide and fungicide as follows : 4 lb. copper sulphate, 4 lb. [illegible] (quick), 4 oz. Paris green, 50 gals. water. Dissolve the copper sulphate [illegible] warm water or by placing in a bag of coarse cloth, and hanging in [illegible] gallons of water to dissolve. Slack the lime in four or five gallons of water, [illegible] strain through coarse cloth or screen. Mix the two, add Paris green, and [illegible] mixture in the remainder of the water. When fruit is nearly matured the [illegible] niacal copper carbonate solution is used as follows: 5 oz. copper carbonate, 2 quarts ammonia, 50 gals. water. It is for the same purpose as Bordeaux mixture.

The following wash for old trees with scurvy bark, also used quite largely in Nova Scotia, in the early spring for cleaning trees, is the potash wash consisting of 3 gals. of water, 1½ to 2 lb. crude potash. This must be applied as a spray before buds swell or burst.

SOURCES OF COMMERCIAL INDIA-RUBBER.

The first of the two Cantor lectures on the sources of commercial india-rubber was given by Dr. Morris, C.M.G., on April 18.

In his opening remarks Dr. Morris said that, since the days when Le Condamine first described the rubber-tree of Brazil, and Don José, King of Portugal, in 1755 sent several pairs of his royal boots to Para in order that they might be covered with the water-proof "gum-elastic," the use of India-rubber has enormously increased. Besides the demand in almost every department of arts and manufactures, the rapid development of cycling, and of the use of rubber tyres for carriage wheels, has added largely to the increased consumption of this interesting article. The quantity of raw caoutchouc imported into the United Kingdom in 1830 was only 23 tons. Even in the year of the accession of our Queen it was about 200 tons. Last year it had increased to 20,000 tons.

The present value of the imports are about five millions sterling. The total trade is probably not less than ten millions sterling. More than one-third of the imports is now received from British possessions. In 1888 only about one-fifth was so received. It is estimated that the world's consumption of rubber is 60,000 tons, of the value of fourteen millions sterling. This stupendous quantity of raw material is laboriously extracted from the milky juice of trees and shrubs belonging to three natural orders, viz., the Spurges *(Euphorbiaceæ)*, the Nettles *(Urticaceæ)*, and the Dogbanes *(Apocynaceæ)*. These plants are distributed over nearly every part of the tropical zone—none are found in the temperate zones—the most important being found in the vast basin of the Amazon, an area almost as large as that of the continent of Europe; others are found on the east and west coastt of Africa, in Assam, and the Malay Archipelago.

Hitherto the preparation of India-rubber has depended upon the crude hereditary art of a semi-savage people—the rubber-hunters—who explore the depths of tropical forests, and obtain the rubber-milk at the sacrifice of millions of trees which, owing to the recklessness with which they have been treated, are yearly decreasing.

The result is that many localities where rubber was once abundantly obtained have almost ceased to produce it. New sources of supply have, it is true, been found in West Africa, especially in Lagos, the Congo State, and Portuguese South-west Africa. But here also the work of destruction is rapidly going on. The collectors have to go further and further into the interior, and the cost of transit is thereby greatly increased. An account was given by the lecturer of an important discovery whereby rubber could be extracted from the milk in a perfectly pure state. This is a mechanical contrivance on the principle of a cream separator. This was likely to prove of great value in the preparation of Central American and some West African rubbers where the milk flows in an appreciable quantity and is capable of being brought in by the collectors.

The rubber trees of Brazil were then exhaustively described, together with the distribution of the various species yielding the Para rubber of commerce. The exports from Para in 1897, including rubber received from Bolivia, Peru, and Venezeul, amounted to 22,650 tons. Of this amount fifty-one per cent. was shipped to the United States and thirty-eight per cent. to the United Kingdom, leaving only about eleven per cent. or 2,500 tons for all other countries. The price of Para rubber, which regulated the price of all other sorts, has been steadily increasing since 1894, when it was 2s. 11d. per pound; in 1895 it rose to 3s 2d.; in 1896, to 3s. 4d.; in 1897, to 3s. 6½d., while the average price for the first three months of 1898 was 3s. 9½d.

At the concluding lecture, delivered April 25, it was stated by Dr. Morris that there is a consensus of opinion that in nearly all localities in Central America the trees of Castilloa elastica are being gradually exterminated. Hence the supply of rubber from Mexico, Guatemala, Nicaragua, and the U.S. of Colombia is steadily diminishing. The interesting tree yielding Ceara rubber (*Manihot Glaviovi*) readily propagates itself, and its area has not apparently sensibly diminished of late years. The people are, however, being attracted more and more into the rubber districts of the Amazon valley, and the amount of Ceara rubber exported is comparatively small. Manabeira rubber, on the other hand, seems to be increasing. The tree (*Hancornia specicosa*) is found in the States of Pernambuco, Bahia, Rio de Janeiro, and extends westward to Matto-Grosso. The rubber is cured by means of alum; it is of a pinkish colour, and the price is generally only one-half of that of fine Para. Passing on to the rubber-producing areas of the Old World, it was stated that the rapid development of African rubber was one of the most remarkable incidents of recent years. As regards the world's commerce Africa now occupies an important place as a source of india-rubber. The value of the imports of African rubber into the United Kingdom during 1896 amounted to over a million sterling. Of this foreign possessions supplied rubber to the value of £206,972, and British possessions £844,804. Up to within a recent period all the rubber produced in Africa was obtained from climbing plants belonging to the genus *Landolphia*, with sweet-scented flowers and edible pulpy fruits. In 1894 a new rubber tree (*Kickxia*) was found at Lagos, from which in 1895 rubber to the value of nearly £300,000 was exported. More recently still another new rubber plant (*Carpodinus*) has been discovered in Africa. This is of a semi-herbaceous character with underground stems which are rasped in water and yield rubber of an excellent quality.

The rubbers of Assam, Burma, Penang, and Singapore were then dealt with. Borneo rubber, although known since 1798, has only come into commerce within the last fifty years. It is yielded by climbing plants, closely related to the Landolphias of Tropical Africa, and is generally of excellent quality. New Guinea rubber is in part yielded by a species of ficus. The natives are said to allow the sap to run over their arms and body, and when hardened they remove it and roll it up into balls the size of cricket balls. The prospects of obtaining some of the future supplies of rubber from cultivated trees were favourably regarded. In selecting sites for plantations, preference should be given to localities in which the trees were already found. Para rubber trees introduced into the East at the expense of the Government of India had done remarkably well in Ceylon, Tenasserim, and the Straits Settlements. In Ceylon such trees were estimated to yield one hundred and twenty pounds of rubber per acre after the tenth year. This would give a probable return of twenty per cent. on the capital invested. In the Straits Settlements the trees were found to yield at an earlier age, and the estimated returns per acre were placed as high as thirty per cent. It was stated that where rubber trees were cultivated under suitable conditions they would probably yield a larger quantity of milk than wild trees; also that the rubber, from the greater care and attention it would receive, would be more uniform in quality, and therefore obtain a higher price.

EXHIBITIONS AND MEETINGS.

ROYAL HORTICULTURAL SOCIETY, April 26.

Although somewhat crowded by reason of the multiplicity of exhibits, it was a splendid display that was brought together on the above date at the Drill Hall, Westminster. Daffodils and early hardy flowers of many kinds, azaleas and rhododendrons, roses in grand condition, ferns, gloxinias, dracænas, orchids in variety, fruits, and vegetables, were all presented in good condition and combined to make up a most interesting exhibition. Novelties were fairly numerous, and there were a few magnificent new orchids.

Floral Committee.

This body had a long sitting and much work to do. A charming collection of roses came from Mr. George Mount, Canterbury, and was a great attraction, for the blooms were all of the finest substance and size, well formed, beautifully coloured, and on sturdy long stems; Catherine Mermet, Ulrich Brunner, Captain Hayward, Niphetos, Anna Olivier, Caroline Testout, and The Bride, were the varieties most fully represented. Altogether about ten dozen flowers were staged, and none could be finer. A silver-gilt Banksian medal was awarded. Mr. Rumsey, Joyning's Nursery, Waltham Cross, staged cut roses in quantity, showing large boxes of good blooms of Niphetos and Maréchal Niel, with Ulrich Brunner, Ella Gordon, Caroline Testout, Mrs. Rumsey, and many others in lesser quantities; a most fragrant exhibition, and one that gained a silver Banksian medal. A magnificent lot of Maréchal Niel roses came from Mr. J. Walker, Thame.

Messrs. R. and G. Cuthbert, Southgate, put up some beautiful Mollis azaleas, all represented by nicely-grown specimens. Nicholaas Beets, golden yellow; Anthony Koster, soft yellow; General Vetter, large flowers, yellow with brown markings; Sebastopol, rosy fawn or salmon; and Madame Anthony Koster, creamy white with brown spots; and J. J. de Vinck, were among the best of a good set; silver Banksian medal. Sir John T. D. Llewelyn, Penllergaer, Swansea, showed a large number of trusses of handsome rhododendrons, all cut from plants growing in the open air, and in shrubberies and woods; there were handsome bouquets of R. Thomsoni, and hybrids from it; R. niveum, R. oclivaceum, R. arboreum album, and R. campanulatum, in splendid form; this was a most interesting and instructive exhibit, and revealed to visitors the fine climate of Penllergaer and the high standard of cultivation its owner maintains. Mr. Fyfe, gardener to Lord Wantage, Lockinge Park, sent a lovely lot of Fortune's Yellow rose; bronze Banksian medal.

Messrs. Linden and Co., Brussels, set up a small group of extremely handsome anthuriums, all scherzerianum forms or hybrids; a variety named Beefeater was remarkable for its high colour, while My Love was notable for its clear pale pink hue; a silver Banksian medal was awarded. Celmesia Munroi and Azaleodendron Edouard Andre were sent by Messrs. James Veitch and Sons. G. F. Wilson, Esq., showed an assortment of blue primrose blooms; also a deep violet purple one, and some lovely crimson varieties from his Weybridge Gardens. Hardy rhododendrons and a new hybrid polyantha rose with soft rose pink blooms, and named Psyche, came from Mesrs. Paul and Son, Cheshunt, the same firm staging J. B. M. Camm, a soft rose-coloured H. P. rose of good form. A pan of the curious Lathræa squammaria, a parasite, was sent by the Dowager Lady Bowman.

An exhibit of anthuriums from Mr. Bain, gardener to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, contained large specimens of A. triumphans, salmon pink; A alba, creamy white; A. elegans, cream, spotted scarlet; A. Rothschildeanum maximum, A. Lawrenceæ, silvery white; A. Andreanum, A. Laingi, blush; and A. Perfection, a huge andreanum seedling. These fine aroids were greatly admired, as they make most effective decorative plants when so well managed as by Mr. Bain; silver Flora medal. Mr. Empson, gardener to Mrs. Wingfield, Ampthill, Bedford, sent a magnificent specimen of Trillium grandiflorum album, with probably a hundred of its beautiful blooms all expanded upon it. Messrs. J. Peed and Sons put up a large semi-circular group of dracænas of varied hues, all well-grown plants, arranged over a bed of ferns and amid graceful palms; all the leading varieties were staged. A large cluster of blooms of the beautiful scarlet Brownea Ariza, one of the finest of leguminous trees, was sent by Mr. F. Moore, Glasnevin Botanic Gardens, Dublin.

From Messrs. Paul and Son, Cheshunt, came a collection of early-flowering hardy plants, mostly in pans; among the brightest were Geum Emodi, Caltha monstrosa, Saxifraga Lindisiana, Adonis vernalis, Trillium grandiflorum, Pulmonaria arvenensis, Doronicum plantagineum excelsum, and Cheiranthes Harpur Crewe; Gerberi Jamesoni, with orange scarlet flowers, and the pretty Royal Scarlet Rose were both staged by the Cheshunt firm. Gloxinias from Messrs. J. Laing and Sons, Forest Hill, S.E., looked well amid ferns and dwarf palms; the variety Mrs. Laing, rich violet purple and white, is a fine contrast to the variety John Laing, rich velvet cherry-red shaded with crimson; the group merited a silver Flora medal. A most interesting display came from Mr. H. B. May, Edmonton, and consisted of a group of gymnogrammas, containing a great variety of sorts. G. Parsons, G. Laucheana, G. Allstoni, G. grandiceps superba, a grand golden form with tasselled and crested fronds; G. auratum, G. Mayi, sulphur coloured, G. pulverulentum, G. argenteo cristatum, G. Wettenhallianum, and G. peruviana argyrophylla, the brightest silver form, were among the best of a handsome collection of well-grown plants; silver Flora medal. Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, showed a small collection of hardy plants in pots and pans; Anemone fulgens, Primula cortusoides, P. frondosa, P. viscosa, and Androsace villosa were in first-rate condition. The firm also staged a group of daffodils, including three grand pans of the pretty Narcissus bulbocodium; Victoria, J. B. M. Camm, Horsefieldi, and large numbers of incomparabilis and poeticus forms made up a bright exhibit. Some magnificent clusters of the huge white-flowered Rhododendron Nuttalli were shown by Mr. Howe, gardener to H. Tate, Esq., Streatham Hill, and were greatly admired. Erythroniums in great variety were remarkably well shown by Messrs. R. Wallace and Co., Colchester; this exhibit should incite those who have not already done so to cultivate Dog's Tooth violets.

To illustrate the lecture given during the afternoon Messrs. J. Veitch and Sons sent a small collection of fragrant-leaved plants, such as eucalypti, cape pelargoniums, diosmas, humea, prostranthum, adenandra, &c. From Kew, the Director of the Royal Gardens sent a few subjects for a similar purpose, these including the pimento, eucalypti, diosmas, pelargoniums, Myrtus communis, chenopodium, Illicium verum, the Star anise, and others. An interesting exhibit consisted of a display of d'oyleys, lamp shades, fans, &c., all made in the West Indies from dried palm frondage cut into patterns, fastened to light material, and decorated with dried fern fronds; small fronds of gymnogrammas and cheilanthes were largely used, and the effect was charming and elegant; the exhibit was made by Messrs. Osman and Co., the horticultural sundriesmen of Commercial Street, and a silver Banksian medal was awarded it.

Daffodils.

A magnificent exhibit of daffodils came from Messrs. Barr and Sons, Covent

Garden; the Tazetta varieties were largely represented and most fragrant; larger varieties were in force, and amongst the most attractive were Victoria, Apricot, Mrs. Walter Ware, Mr. P. Milner, Gloria Mundi, Glory of Leiden, Prince of Orange, Weardale Perfection, Madame de Graaff (a grand bunch), Shakespeare, Maxima, Poeticus poetarum, P. grandiflora, &c. Some beautiful tulips, not forgetting T. Greigi, made up a fine exhibit; silver Flora medal. Messrs. J. R. Pearson and Sons, Chilwell, contributed a large display of daffodils in variety, staging them in neat bunches, and not crowded together; the Burbidgei varieties were specially clean and fresh, and the trumpet forms also; Glory of Leiden, Beauty of Haworth, J. B. M. Camm, Madame de Graaff, Weardale Perfection, Albicans, Emperor, John Nelson, Maximus, and Princess Ida were all beautifully staged; Leedsi amabilis, Burbidgei Vanessa, Siddington, Barri Conspicuus, Sir Watkin, Mrs. Langtry, Duchess of Westminster, Maurice Vilmorin, and Johnstoni Queen of Spain were among the finest and most interesting of the other varieties on view; this was a very pretty display, and contained not less than seventy very distinct varieties; silver Flora medal. Daffodils also were shown in grand form by Messrs. J. Veitch and Sons, Chelsea; the bunches were staged rather closely together, but the flowers were all first-rate, and looked handsome over the groundwork of maidenhair fern; silver-gilt Banksian medal.

ORCHID COMMITTEE.

The orchid committee had a large number of plants to adjudicate upon, and among them were some of the finest novelties yet produced this season. The groups were scarcely so extensive as on some occasions, but were nevertheless very good and effective.

Some particularly handsome forms of Cattleya Mendelli were exhibited by Messrs. Hugh Low and Co., one, named Mrs. John Bradshaw, being especially beautiful, by reason of its large and highly-coloured lip; C. Lawre-Mossiæ, whose parentage its name betrays, was a notable and handsome orchid, giving evidence of its origin; a handsome form of Odontoglossum Pescatorei and others of O. cirrhosum, O. Andersonianum, O. crispum, and O. Ruckerianum attracted attention, as did Oncidium St. Legerianum, and masses of Dendrobium Bensoniæ, silver Banksian medal. Mr. Wiffen, gardener to J. Bradshaw, Esq., The Grange, Southgate, showed a few charming orchids, including the chaste Cattleya intermedia alba, Odontoglossum crispum Whiffeniana, O. luteo-purpureum sceptrum, and Dendrobium Jamesianum; a vote of thanks was accorded. Mr. Smith, orchid grower to the Right Hon. J. Chamberlain, Highbury, Birmingham, sent a few interesting hybrids, including several plants of Lælio-cattleya Highburyensis, obtained a few years ago by crossing C. Lawrenceana with L. cinnabarina; Epicattleya guatemalensis, a cross between Epidendrum aurantiacum and Cattleya Skinneri, is more interesting than beautiful; a vote of thanks was accorded.

From their Chelsea Nurseries Messrs. J. Veitch and Sons sent a large pan of Masdevallia Veitchiana, with two dozen brilliant blooms, Lælia Latona, finely-flowered, and represented by six specimens: Brassia bracheata, Cattleya Philo, a cross between C. iricolor and C. Mossiæ, and having blush sepals and a gold and rose-purple lip; and Lælio-cattleya Thorntoni, a grand hybrid between Lælia Digbyana and Cattleya Gaskelliana, described fully elsewhere. Two other grand orchids were Lælio-cattleya Wellsiana Langleyensis and Cattleya Schröderæ amabilis; silver Banksian medal. Mr. Howes, gardener to W. Cobb, Esq., Tunbridge Wells, sent a freely-flowered plant of the rarely seen Dendrobium albo-sanguineum, Cattleya amethystina Cobb's var., Cypripedium Gertrude Hollington, with three flowers, and a fine variety of Odontoglossum polyxanthum. Mr. Bond, gardener to C. L. Ingram, Esq., Elstead, Godalming, sent Cattleya Sedeni, a hybrid between C. Lawrenceanum and C. Percivaliana, and having large rosy purple flowers. Mr. Holbrook, gardener to E. Ashworth, Esq., Harefield Hall, Wilmslow, showed the beautiful Cattleya Mendeli, Ashworth's var., pure white, save for a lemon tint in the throat. A beautiful form of C. Schröderæ also came from the Harefield collection, and is named after it.

Mr. Barnes, gardener to the Duke of Westminster, Eaton Hall, sent a very pretty form of Odontoglossum Pescatorei named Duchess of Westminster; this had a number of rosy-crimson spots over a pure white ground. From Sir Trevor Lawrence's collection at Dorking Mr. W. White brought Mormodes [illegible], a very curious species, with long spikes of rich ruby claret-coloured flowers; a beautiful Odontoglossum crispum also came from Dorking. A most distinct and unnamed cymbidium was shown by Mr. J. Sparks, Heathcote, Ewhurst, Surrey. This has a whitish mark on the small blackish-brown lip; it is probably a form of C. canaliculatum. Mr. S. Cooke, gardener to De Barri Crawshay, Esq., showed his magnificent form of Odontoglossum triumphans, named Lionel Crawshay; this is a finely-formed and splendidly-coloured variety, and probably a unique specimen. Mr. H. Greenwood, Hasledene, showed a pretty form of Odontoglossum Humeanum with cream lip and brown markings on the [illegible] sepals and petals. Mr. H. T. Pitt, Rosslyn, Stamford Hill, sent a highly-coloured Odontoglossum triumphans.

Messrs. Linden and Co., Brussels, staged a large exhibit of odontoglossums, and a few other orchids; there was a splendid variety of forms and colours of O. triumphans, O. Andersonianum, O. crispum, O. Pescatorei, O. cirrhosum, O. Wilckeanum, O. Ruckerianum, &c. A showy Miltonia vexillaria occupied a central position; this was richly coloured, and named Memoria Lindeni. O. Wilckeanum Lindeni, white ground; O. crispum Prince Albert, red spots, [illegible] on each segment; Cattleya Mendelli the Pearl, Cymbidium Lowianum, with [illegible] crimson-tipped lip; and Cypripedium Rothschildeanum were among the finest orchids staged in this group. A silver-gilt Flora medal, the highest award on the occasion, was awarded the Brussels exhibit. Messrs. B. S. Williams and Son, Holloway, gained a silver Banksian medal for their collection of orchids, which consisted of many handsome varieties of the beautiful Cattleya Mendelli and a large number of odontoglossums, principally first-rate O. crispum, O. luteo-purpureum, O. Halli, and O. Harryanum forms, the latter especially good.

FRUIT AND VEGETABLE COMMITTEE.

Vegetables were fairly well shown, and from Mr. H. Martin, gardener to Lord Leigh, Stoneleigh Abbey, Kenilworth, came a splendid lot of seakale, that merited a cultural commendation. Messrs. J. Veitch and Sons, sent broccoli [illegible] Favourite, with close oval heads of great value at this season. Mr. J. Read, Buthy Park, Burton-on-Trent, gained an award of merit for a new green-flowered sprouting borecole, evidently a late and free-growing sort.

Mr. G. Wythes, gardener to Earl Percy, Syon House, Brentford, staged a really good collection of vegetables for the time of year. There were asparagus, seakale, Chelsea Gem and Carter's Early Morn peas; Ne Plus Ultra and Early Favourite French beans; Veitch's Ashleaf, Sharpe's Victor, and English Beauty potatos; Telegraph and Seedling cucumbers, leeks, mushrooms, several sorts of kale, broccoli, Ellam's Dwarf cabbage, spinach, cabbage lettuce, endive, [illegible] Nantes carrots, and Conqueror tomatos were the principal varieties. This exhibit, which gained a silver-gilt Banksian medal, illustrated in a marked manner what great variety of vegetables and salading has to be provided by a large [illegible]

CHELSEA, LONDON, S.W.

ment, and also how well our leading gardeners meet the great demands made upon them even at this end of the season. A similar award was made to Mr. Empson, gardener to Mrs. Wingfield, Ampthill House, Bedford, for an extensive collection of first-rate produce. A bunch of bananas (Musa Cavendishi) held the post of honour, and was supported by pots of strawberries, in full fruit, and dishes of Royal Sovereign and Sir Joseph Paxton strawberries; there were two mounds of apples, the variety being a late-keeping seedling from Beauty of Kent. Vegetables were well represented by Carter's Mammoth broccoli, new potatos, tomatos, asparagus, carrots, seakale, leeks, onions, radishes, cucumbers, rhubarb, &c., and altogether there were thirty-eight dishes of fruit and vegetables.

In competition for the Veitch flavour classes, the first prize for apples was won by Mr. Bullock, gardener to C. P. Serrocold, Esq., with Hereford Pearmain; Colonel Brymer, Dorchester, secured second prize with Allen's Everlasting.

READING AND DISTRICT GARDENERS' ASSOCIATION.

ONE of the most interesting and successful meetings in the annuals of this association was that held on Monday, when the prizes offered by Mr. Leonard Sutton at the commencement of the season, 1898, for the best essays on "How to keep the Greenhouse Gay from October 1 to March 31," and "How to Crop the Vegetable Garden to ensure the best varieties of vegetables from October 1 to March 31," were awarded to the successful competitors. The interest taken in the competition was greater than anticipated, thirteen members sending in papers, and it was not a matter of surprise that a good gathering of members assembled on Monday evening to learn the result, and to hear the prizewinning papers read by their writers. After the formal business had been transacted, Mr. C. B. Stevens announced the awards as follows: "How to keep a Greenhouse Gay." (1) Mr. A. W. Blake, Foreman, The Gardens, East Thorpe, Reading; (2) Mr. G. Stanton, The Gardens, Park Place, Henley-on-Thames; (3) Mr. John Botley, Foreman, The Gardens, Warfield Hall, Bracknell. "How to Crop the Vegetable Garden." (1) Mr. E. Trollope, The Gardens, Coombe Lodge, Whitchurch; (2) Mr. H. Wilson, The Gardens, Lower Redlands, Reading; (3) Mr. G. Hinton, The Gardens, Sherwood Lodge, Reading.

The judges were Mr. James Hudson, Gunnersbury Park, and Mr. Edwin Beckett, Aldenham House, Elstree. Mr. Leonard Sutton in presenting the prizes said that he considered the subject of essay writing was one of the most useful and beneficial to the members that the society could take up, for it encouraged the putting of one's ideas on paper, and at the present time it was those gardeners that could go to their employers with well thought-out ideas that would prove successful, and it would also be of the utmost value to the young gardeners who entered these competitions, for they would reap the benefit of their study and research in after life. The President then called upon the various winners to read their papers, and although, of course, all were on the same subject, yet they were treated from different standpoints, thus creating great interest amongst the members present. A hearty vote of thanks was passed to Mr. Leonard Sutton for his kindness in giving the prizes, and also to the members for reading their papers.

Cut flowers were staged by Mr. Woolford, The Gardens, East Thorpe, including two good forms of Odontoglossum crispum, two fine types of Cattleya Lawrenciana, spikes of Amaryllis Empress of India, and spathes of Anthurium Scherzerianum Wardi, also flowering sprays of Prunus sinensis flora pleno by Mr. Swansborough, Warfield Hall Gardens, whilst vegetables were shown by Mr. Stone and Mr. Hinton, including some nice heads of Sutton's April cabbage.

ANSWERS TO CORRESPONDENTS

Sport from Escallonia macrantha.—T. F., Isle of Man: You evidently have a very handsome shrub, and one that cannot fail to become popular, if it proves as free as the parent. It should also prove valuable if carefully propagated until you hold a good stock. The name you suggest would be a suitable one, used after the manner of Escallonia macrantha Ingrami.

Rose and Fruit Cultivation, &c.—H. B., Dover Beck: Suitable books for you will be "The Amateurs' Rose Book," 3s. 6d. (W. H. and L. Collingridge, 148, 149, Aldersgate Street, E.C.); "Fruit Culture for Amateurs," 3s. 6d. (L. Upcott Gill, 170, Strand, W.C.); Nicholson's "Dictionary of Gardening," 4 vols., £3 3s. (L. Upcott Gill)—we understand that a new edition of this work is forthcoming at an early date: and "Hooker's Elementary Botany," 1s. (Macmillan and Co.)

R.H.S. Meetings.—H. G., Isle of Wight: The meetings of the Royal Horticultural Society are duly notified in our columns the week previous to their being held; usually they are notified in the paragraphs following the "Notes of the Week," and always in the "Engagements for the Ensuing Week." The next meeting will be held at the Drill Hall, St. James's Street, Victoria Street, S.W., on May 10. Parcels for exhibition should be sent to the superintendent of the R.H.S. at the Drill Hall. The secretary of the R.H.S. is the Rev. W. Wilks, and his official address is 117, Victoria Street, S.W.

Cultivation of Smilax.—A. C.: The plant to which you refer is no doubt Myrsiphyllum asparagoides, a most useful plant for table and similar decoration by reason of its long growths, clothed with branchlets of rich green foliage. It requires a warm greenhouse, and does best planted out in a bed of loam and leaf-soil to which a little mushroom-bed manure may be added if available. Plenty of moisture is essential, and when well established and growing freely liquid manure may be given frequently. The myrsiphyllum can be easily grown at the foot of the back wall of a greenhouse, and each growth should be provided with a long string up which to twine, when this is done it is an easy matter to cut out one or more growths as required, and have them their full length; if allowed to entwine about each the growths are of little value.

Lumps on Chestnut Stems.—J. M., Hemel Hempstead: There is no need to fear for the health of the tree because the lumps to which you refer are evidence of its vitality and vigour. No doubt the red-flowered variety has been worked upon a stem of the common horse-chestnut, standard fashion, and as often happens the latter is endeavouring to grow. Where a bud or branch originally existed and was not properly removed other minor buds have developed, and these, being rubbed off as produced, have induced the irregular lumps about which you are concerned, and which are once again doing their best to make growth. Sometimes when the head of a tree has been severely pruned and lopped the proper balance between head and root is broken; in its endeavour

BENETFINK AND CO., CHEAPSIDE, LONDON, E.C.

to regain this balance long-dormant buds start into growth along branches and trunk, and into these the energies of the tree are directed. It would be risky to cut off all the lumps, as in the case of the one sent, but much might be done to improve the appearance of the stems in this way, removing a few each year and tarring the wound over with Stockholm tar.

Failing Cucumbers.—W. W., Norwich: Cucumbers do not like a great bulk of soil, but when well rooted they need frequent and small top-dressings of rich material. A large bulk of very rich soil such as you have becomes sour quickly, especially when so heavily and frequently watered as your letter suggests. It is very evident that you have too large a bulk of very rich soil, and that this has to a large extent become sour and cold owing to excess of moisture and lack of ventilation. Give less water at the roots, and allow a very little ventilation on favourable opportunities; shut up early in the afternoon, and at the same time damp the paths, walls, and other exposed surfaces. A light top-dressing of lime will prove useful, and should be carefully pricked into the staple soil. The temperatures of the house and water are all right. We shall be glad to answer any further direct questions upon the subject.

Names of Plants, &c.—S. M. C., Uppingham: Allium neapolitanum; quite hardy, but extensively used for greenhouse and conservatory decoration.

R. R., Woolwich: The creeping plant is the Ground Ivy (*Nepeta Glechoma*); the orchid is Oncidium tigrinum var. unguiculatum.

J. C., Bath: Dendrobium Pierardi.

Douro, Reading: A young plant of Aloe variegata.

The mean reading of the Barometer during the week at Greenwich was 29·84 inches, and that of the Thermometer 46°·4, the latter being 1°·9 below the week's average in the 50 years 1841—90. The direction of the wind was north-easterly, the horizontal movement of the air being 27 per cent. below the week's average in the 16 years 1860—75. The duration of registered bright sunshine in the week was 46·4 hours. No rain was measured during the week.

IMPORTANT DISCOVERIES OF GOLD are no doubt of great value to society, especially at a time like the present, when the money market is so tight and poverty so distressing. Still, however, there are some things in this world far more precious than gold, in spite of the immense influence it wields over mankind. Health, for instance, cannot be purchased for money, but it may be preserved and secured by the use of Holloway's Pills. No family should be without them, as they are equally good in their effects for either old or young. No complaint can for long withstand their healing power. They drive out all impurities from the blood, strengthen the digestive organs, and cleanse the stomach.—[ADVT.]

MARKETS.

Covent Garden.

THE market is well supplied with all kinds of produce, and there is an even demand, so that prices have not altered much. Seakale, rhubarb, and asparagus are ch [illegible] somewhat, but apples and pears fetch high rates. Potato trade moderate; [illegible] vegetables rather coarse and better sorts selling well.

FRUIT.—English grapes, 3s. to 5s.; Belgian, 2s. 6d. to 3s. 6d. per lb.; Valencia oranges, 9s. to 20s. per case; Jaffa, 9s. to 12s. per box; lemons, 8s. to 15s. per case; English tomatos, 8d. to 10d. per lb.; Canary, 1s. 2d. to 1s. 6d. per tray, 3s. 6d. to 4s. 6d. per case; pineapples, 2s. 6d. to 6s. each; bananas, 5s. to 9s. per bunch; Californian pears, 11s. to 16s. per case.

FLOWERS.—Arums, 2s. to 4s.; carnations, 1s. to 3s.; eucharis, 3s. to [illegible]; gardenias, 2s. to 3s.; Lilium Harrisi, 4s. to 6s.; tea roses, 6d. to 1s.; pink roses, 3s. to 6s.; red roses, 2s. to 4s.; cattleyas, 6s. to 9s.; Odontoglossum crispum 1s. 6d. to 4s.; and tuberoses, 1s. to 1s. 6d. per dozen blooms; Adiantum cuneatum, 4s. to 8s.; marguerites, 2s. to 4s.; narciss, various, 1s. 6d. to 4s.; hyacinths, 4s. to 6s.; daffodils, 2s. to 4s; tulips, 3s. to 6s.; mignonette, 2s. to 4s.; pelargoniums (scarlet), 4s. to 9s.; wallflowers, 2s. to 3s.; primroses, 9d. to 1s.; and violets, 9d. to 3s. 6d. per dozen bunches; azaleas, 6d. to 1s.; stephanotis, 4s. to 6s.; lily of the valley, 6d. to 1s. 6d.; and pelargoniums, 6d. to 1s. per dozen sprays; bouvardias, 6d. to 8d.; white lilac, 3s. to 4s. per bunch.

VEGETABLES.—Egyptian onions, 7s. 6d. to 8s, 6d. per cwt.; English spring, 2s. 6d. to 3s. 6d. per dozen bunches; French giant asparagus, 7s. to 10s. 6d.; Toulouse, 3s. to 4s. 6d.; Spanish, 1s. 4d. to 1s. 8d. per bundle; broccoli, 9d. to 2s. per dozen; natural rhubarb, 2s. 6d. to 3s 6d.; forced, 1s. to 1s. 6d.; new carrots, 7s. to 9s. per dozen bunches; lettuce, 9d. to 1s. 3d.; cos, 2s. to 2s. 6d.; cucumbers, 3s. to 6s.; endive, 1s. 6d. to 2s. per dozen; mushrooms, 6s. to 8s.; eschallots, 1s. 6d. to 2s. per 12 lb.; spinach, 2s. per bushel; Canary new potatos, 10s. to 14s.; Malta rounds, 8s. to 10s.; Algiers, 10s. to 14s. per cwt.

Borough Potato Market.

A quiet trade exists with fairly moderate supplies and steady prices. New potatos are in fairly good request.

ENGAGEMENTS FOR THE ENSUING WEEK.

AUCTION.

MONDAY, MAY 2.—Greenhouse Plants, Pond Lane, Clapton.

TUESDAY, WEDNESDAY, and FRIDAY, MAY 3, 4, and 6.—Ferns and Plants, Home Grown Lilies, and Orchids, Central Sale Rooms, Cheapside.

WEST'S PATENT IVORINE PLANT LABELS

NAME TO BE WRITTEN ON WITH ORDINARY LEAD PENCIL OR PEN AND INK.

The "Ivorine" Writing Disc, Being made of a specially prepared substance, having the properties of real ivory, is imperishable, and does not corrode or eat away, like wood and metal labels; and being ivory-white, when written upon it shews to perfection. And also, as the writing is on the Ivorine itself it is permanent, though washable, and does not become unreadable, as is the case with all painted labels, as the paint gets old. It is for all purposes, and will last a century, either in a greenhouse or out in a garden, and not only is it always ready for use, and may be written on both sides, but the name when written in pencil may be easily rubbed off, and so used as many times as desired.

Samples and Lists of the West's Patent Specialities post free.
Price, **9d.** per dozen; **8s.** per gross, Carriage Paid.
Supplied by all Nurserymen, Florists, &c.

WEST'S
PATENT
IVORINE
PLANT LABELS
NAME TO BE WRITTEN ON WITH ORDINARY LEAD PENCIL OR PEN AND INK.

THE "IVORINE" WRITING DISC,

Being made of a specially prepared substance, having the properties of real ivory, is imperishable, and does not corrode or eat away, like wood and metal labels; and being ivory-white, when written upon it shows to perfection. And also, as the writing is on the Ivorine itself it is permanent, though washable, and does not become unreadable, as is the case with all painted labels, as the paint gets old. It is for all purposes, and will last a century, either in a greenhouse or out in a garden, and not only is it always ready for use, and may be written on both sides, but the name when written in pencil may be easily rubbed off, and so used as many times as desired.

Samples and Lists of the West's Patent Specialities post free.
Price, **9d.** per dozen; **8s.** per gross, Carriage Paid.
Supplied by all Nurserymen, Florists, &c.

The LEEDS ORCHID Co.,

SOW NOW.
SUTTON'S Perfection CALCEOLARIA. Profusion of bloom, large and well-formed flowers, diversity and splendour of colouring, combined with a dwarf and vigorous habit, are the characteristics which have secured the supremacy of our magnificent strain of Calceolarias. To maintain its pre-eminence we continue to cross the finest flowers, and from these our seed is saved.
Mixed colours, per packet, 3s. 6d. and 5s., post free.

SUTTON'S Perfection CALCEOLARIAS. Mr. W. Westbury, Gardener to Chas. Showell, Esq., says: "I herewith post you a photograph of a group of Calceolarias grown from your seed, which is by far the finest strain I have ever seen. Mr. Showell is highly delighted with them, and everyone who sees them is surprised at the brilliant show they make"

1898 FORBES' CATALOGUE 1898

(over 150 pages—nearly 150 illustrations) of

FLORIST'S FLOWERS and HARDY BORDER PLANTS

is got up REGARDLESS of TROUBLE or EXPENSE, with the result that it is by UNANIMOUS CONSENT pronounced the most COMPREHENSIVE, most ACCURATE, most RELIABLE, most COMPLETE, and BEST EXTANT.

It gives full and ACCURATE DESCRIPTIONS of everything in the way of FLORIST'S FLOWERS, also COLO[illegible] HEIGHT, TIME of FLOWERING, and PRICE of all the best HARDY BORDER PLANTS, together with their ENGLISH or COMMON NAMES, and a mass of other VALUABLE INFORMATION that cannot be had elsewhere.

It is, in fact, a veritable REFERENCE-BOOK, invaluable to all growers of these plants, and should be in the hands of all intending purchasers. Free on application.

JOHN FORBES, Nurseryman,

HAWICK, SCOTLAND.

ESTABLISHED 1870.

DAHLIAS.

H. CANNELL and SONS, sole introducers of the Cactus and Single Varieties, beg to assure all admirers of this family that they have for 25 years been awarded Highest Honours for the best General Collection, and that their Stock of 40,000 in 600 varieties is the completest and best kept in England, and give the greatest satisfaction from one end of the world to the other, as a proof append the following:—

G. Herbert Hasyard, Esq., Charlottetown, Prince Edward Island, North America. 31/3/98.

"I wish to thank you for dahlias. I got some from four different places in England, which more or less failed. Whereas all yours are fine plants."

Send for Illustrated Catalogue, free to coming customers.

THREE INSERTIONS FOR THE PRICE OF TWO!

BARR and SONS have on their Register several competent HEAD GARDENERS. They will be pleased to furnish full particulars on application.—12 and 13, King Street, Covent Garden, London.

FOREMAN (Inside, or General); age 26; good all-round experience; highly recommended; two years in present situation, 2½ previously as foreman.—E. Hewer, The Gardens, Itton Court, Chepstow, Monmouthshire.

FOREMAN (Inside, or General) in a well-kept establishment; age 30; thorough knowledge of gardening in all branches; good references.—W. D., 19, King Street, Chelsea, S.W.

FOREMAN in medium-sized place or Journeyman (First) in large establishment; highly recommended.—For all particulars apply to Head Gardener, Ranston, Blandford.

FRANK GARRETT, The Firs, Woodford Wells, Essex, is OPEN to ENGAGE with any lady or gentleman requiring the services of a thoroughly experienced Head Working Gardener; married; age 32; excellent testimonials; two years head.

GARDENER (Head), age 33; single, otherwise when suited, 18 years' thorough practical experience in growing grapes, peaches, pines, figs, melons, tomatos, cucumbers, orchids, stove and greenhouse plants, chrysanthemums, kitchen and flower garden, house and table decorations, and all the requirements of a good establishment; excellent testimonials.—Please apply J. Nesling, Ganarew Cross, Monmouth.

GARDENER (Head).—A. W. Smith, age 30, eight years Foreman with Mr. James Douglas, also two years' excellent character as Head, seeks re-engagement; life experience in all branches; thoroughly competent; highest references.—Merryland's Cottages, Bookham, Surrey.

GARDENER (Head) where three or four are kept; life experience in all branches; age 40; married, two children; good references.—Address J. Denton, Up Down Hill, Windlesham, Surrey.

GARDENER (Head); where two or more are kept; age 27; single; life experience in all branches Inside and Out; excellent character.—W. Peters, Gardens, High Firs, Harpenden, Herts.

GARDENER (Head); age 35; thoroughly [illegible] Inside and Out; early and late forcing; 6½ [illegible] in present place.—A. Stock, Gardens, Bury Hall, [illegible], [illegible].

GARDENER (Head), or Gardener and Bailiff.—Scotch; age 46; married; no family; thorough all-round life experience in superior places; first-class testimonials, and reference to present employer.—J. L., The Gardens, Knowle Hall, Warwickshire.

GARDENER (Head Working); age 34; married; thorough knowledge of gardening in all branches; disengaged; excellent character from past employers.—Wm. [illegible] Road, Tonbridge.

GARDENER (Head Working); married; [illegible] thoroughly experienced and practical in all the branches; 12 years' excellent character as head from present employer.—W. Ball, Bramcote, Notts.

GARDENER (Head Working); age 39; married, one child, 12; thoroughly practical in all branches; 25 years' excellent characters; land stock if required.—Stevens, 83, Wood Street, High Barnet, Herts.

GARDENER (Head Working).—Mr. G. Cliffe, Gardener to Earl Egerton of Tatton, wishes to RECOMMEND his General Foreman, G. Howe; previous 2 years foreman, Stoke Park, Slough; 14 years' experience.—Howe, Tatton Gardens, Knutsford.

GARDENER (Head Working), age 30; life experience; thoroughly understands flowers, fruit, and vegetables, including orchids and carnations; well recommended by past and present employers.—Dawson, Rangemore Gardens, Burton-on-Trent.

GARDENER (Head or good Single-handed); life experience in vines, melons, cucumbers, tomatos, stove and greenhouse, fruit, flowers, and vegetables; age 40; married, no family; good character.—Gardener, Elm Cottage, Rickmansworth.

GARDENER; understands his profession in all its branches; age 40; married, one child; life experience; good reference.—W. F., 29, Highgate Hill, N.

GARDENER (good Single-handed or where help is given); well up in all kinds of fruit trees, growing and forcing seakale, tomatos, mushrooms, cucumbers, and pleasure ground work; understands land and stock; poultry if required; 15 years' excellent character from last situation; married; age 46; one daughter; left through employer's death.—J. Sansom, Barcote Cottage, Faringdon, Berks.

GARDENER (Single-handed, or with help); understands vines, greenhouse, flower and kitchen garden, and the general routine of the business; seven years' excellent character; disengaged; age 43; married, no family; total abstainer.—W. Shilvock, near The Reform, Bridge Road, Maidenhead.

GARDENER (Single-handed, or good Second); age 24; 8 years' practical experience Inside and Out; good characters; disengaged.—W. Barron, Poona House, Cosham, Hants.

GARDENER (Single-handed); age 25; married when suited; seven years' experience in good gardens; Inside and Out; excellent references from past and present employers.—G. Mann, The Gardens, High Firs, Harpenden, Herts.

GARDENER (Second); Inside and Out, SEEKS SITUATION in private establishment; age 25; 10 years' experience; good character.—C. Doman, care of Mr. Warriner, Grange Road, Egham, Surrey.

GARDENER (as Second, or otherwise, in first-class place); Inside, or Inside and Out; good character, and general knowledge of work; age 20.—H. Penn, The Gardens, Mole Lodge, West Molesey, Surrey.

GROOM or GROOM-GARDENER; ride and drive well; understands stable duties and good kitchen gardening; married, one child, 7; age 37; good character.—H. Terry, Station Road, Hayes, Kent

GARDENER (Under or Journeyman); age 22; seven years' experience; good references; abstainer.—A. Hibbert, Church End, Arlesey, Hitchin, Herts.

JOURNEYMAN (Inside and Out); six years' experience; good character.—C. Cutler, Halwill Green, Beaworthy, Devon.

JOURNEYMAN (Inside, or Inside and Out); age 21; having been in last situation 2 years can be well recommended; bothy preferred.—E. Fryer, The Lodge, West Drive, Brighton, Sussex.

JOURNEYMAN (Under); Inside, or Inside and Out; in good Private Establishment; age 19; good experience; bothy preferred.—J. Treagus, Waldeck Cottage, Lyne Lane, Chertsey, Surrey.

RICHARD SMITH and CO., beg to announce that they are constantly receiving application from Gardeners seeking Situations, and that they will be able to supply any Lady or Gentleman with particulars, &c.—St. John's Nurseries, Worcester.

SITUATION WANTED in gentleman's garden as Second under glass; 12 years' experience; age 25; single; abstainer; good character for 4½ years from present situation, 7½ years previous.—W. Wilshier, Eaton Socon, St. Neots, Beds.

UNDER-GARDENER, or Single-handed, by young man, age 22; with knowledge of orchids; good references; state wages; London or suburbs preferred.—Arthur, Tanswell Stores, Earl's Colne, Essex.

WANTED, a SITUATION as Under Gardener; five years' good character; willing to make himself useful; age 18.—Apply Walter Merrett, Habin Rogate, near Petersfield, Hants.

YOUNG MAN SEEKS SITUATION as Improver (Inside); age 20; highly recommended by employer.—F. Bonney, Colton House, Rugeley.

YOUNG MAN, age 28, REQUIRES SITUATION as Under Gardener; good character from last place. F. Radbourne, Woodspeen West, Newbury, Berks.

Situations Vacant.

Advertisements under this heading are charged 2s. 6d. for Four lines (32 words), and 6d. per line of eight words after.

LAD WANTED as Apprentice for Florists.—Apply C. J. Bungay and Son, F.R.H.S., Beech Nursery, Loughborough Road, Brixton, S.W.

WANTED, a Young MAN, as Under Gardener; Inside and Out; abstainer preferred.—Address, stating age, experience, salary required, R. Wingate, Oakhurst, Hildenborough, Tonbridge.

WANTED, a Young MAN, as Second, under glass; must be quick and willing; wages 18s., and bothy.—Walter Jinks, The Gardens, The Beeches, Walton-on-Thames.

WANTED, two GARDENERS, one to take charge of small Nursery and one for jobbing work and fill up time in nursery; permanent to suitable men.—By letter first, 55, Danbury Street, Islington, N.

WANTED, Young MAN, about 18 to 20, with fair knowledge of gardening Inside and Out, and attend fires; please state wages, with lodgings found.—Address Gardener, Garratt's Hall, Banstead, Surrey.

YOUNG MAN WANTED for jobbing; must be used to scythe; fill up time in Nursery.—Allin's, Highbury Place Nursery, Highbury, London.

NOTICE TO ADVERTISERS.

Owing to the continued increase in circulation, the "Gardeners' Magazine" now goes to press on Wednesday. No advertisement can be guaranteed insertion, or altered, unless received before Four p.m. on that day.

NOTES OF THE WEEK.

PROGRESS IN FRUIT CULTURE.

THE several papers read at the conference held at the Crystal Palace under the auspices of the Royal Horticultural Society are included in the current issue of the society's journal, and form an important part of the contents of that publication. While perfectly aware that all the papers contain much that is of value, we turned with special interest to that in which Mr. George Bunyard discusses the progress made in fruit culture during the past sixty years, for this journal has been closely identified with the question for a long time past, and the author is properly recognized as an authority on matters relating to fruit production. Mr. Bunyard's paper, as might well be expected, contains much useful information, and well deserves careful perusal, but it hardly realises our anticipations, and we confess to a sense of disappointment in reading it. We fail to find any reference whatever to the work accomplished by the late Shirley Hibberd, who, by his vigorous crusade against the repressive system of pruning which so long held sway in the fruit garden, rendered services of so high a degree of value that they should have recognition, however brief, in a sketch of the progress of fruit culture during the Queen's reign. Early in 1876 Mr. Hibberd commenced his attack upon the practice of pruning, which rendered it impossible for the trees to give an adequate return for the labour bestowed upon them, and although he had to bear the brunt of a keen controversy and much misrepresentation, he in no way deviated from the course on which he had entered until he had accomplished the object he had in view and effected a reform in the views generally held with regard to the use of the pruning knife. Previous to that year, as Mr. Hibberd stated in his famous lecture given before the Society of Arts on February 9, 1876, it appeared "to be generally agreed that the treatment of fruit trees in every stage of their existence should be such as to prevent their growth, so that the orchard shall no longer be adorned with fully-developed examples of their respective kinds." Starving stocks were largely employed, and the code of management most commonly recommended included systematic root pruning and summer pinching, with the result that gardens became filled with stunted trees "that cost as much time and labour in the production of a mere pounds of fruit, that would have been sufficient for a ton." Mr. Hibberd persistently urged, and with good effect, that before the cultivator can harvest plentiful supplies of fruit, he must have the trees to produce it. In accordance with those views, he advised that the trees should be allowed to extend both above and below the surface, and that they should above all things be encouraged to so extend their branches that a due proportion of flower and fruit buds might be produced. It was in 1876 a quite common practice at the winter pruning to cut the whole of the shoots of the previous season back to three or four buds, with the result that in a few years the trees became crowded with spray utterly useless in fruit production. To combat this practice, it was urged that the leading branches should be allowed to grow and surplus shoots be removed, for, as cultivators at the present day fully recognise, when a shoot of moderate strength is slightly shortened it will, in the course of the following season, produce flower buds along the greater part of its length, and in the second year bear fruit, provided other conditions are favourable. The advice was acted upon in numberless instances, with the result that trees which previously gave a very small return, now produce an abundance. In hundreds of gardens may be seen bush and pyramidal trees that present a scarred, cankery appearance, some four, five, or six feet from the ground, whilst above the branches present a smooth and otherwise healthy appearance. These scars indicate the point to which the trees were previously cut back, while the growth above is the result of the more rational course of procedure advocated by Mr. Hibberd. The increase in the productiveness of fruit trees in gardens as the result of the reform effected cannot be estimated with any degree of exactitude, but it must represent a money value of some thousands of pounds annually.

EXHIBITION OF CUT FLOWERS.

AS we are within a measurable distance of the Temple Show, it may be well to recall the strictures which are made year after year upon some of the exhibits, which, however beautiful the flowers constituting them may be individually, are wanting in attractiveness, owing to the lack of taste in their arrangements. Although in some cases this is doubtless due to inadequate space granted for the quantity shown, this is but a poor excuse, if any, since the exhibitor knows perfectly well beforehand how much space is at his disposal, but obviously does not grasp the fact that crowding that space as if it were a market stall, is less satisfactory than would be a selection of the best and exclusion of second rates, and consequent higher grading all round. Year after year we find the "market bunch" system adopted, where half a dozen good blooms per cluster would look infinitely prettier and afford a far better opportunity of judging the flowers so shown. Take the flowers as they grow naturally and we find a perfect harmony between them and their foliage, the one setting off the other; the sweet pea for instance, with its characteristic leafage and tendrils, forms a charming spray, but cut a number of these sprays, put no leaves at all, and cram the lot into something little better than a ginger-beer bottle, and where is the natural grace and what are the qualifications of such a bouquet for the first show in London? The curious thing about such exhibits is that the show itself affords annually a liberal education which should lead to their elimination, but first and foremost the actual plants themselves, as they grow, are the best teachers. Next to the proper exhibition of cut flowers individually, comes, of course, the grouping and general arrangements, and here again crowding is a mistake, and very much may be done to enhance effect, by careful arrangement of colours, and the introduction of suitable foliage plants, by way of set off. It is a question whether it might not prove advisable in cases where exhibits are not up to the mark, to call upon the exhibitors when applying for space at future shows, to define their intentions, or failing this, to erect a special tent in some secluded corner, which should tacitly occupy the same status as the Chamber of Horrors at Madame Tussaud's.

A TROUBLESOME ORCHARD PEST.

AS one result of the more intelligent interest that is being taken in economic entomology by the general body of fruit growers, we have recently received from widely separated districts branches of apples that had been injured in a manner that evidently greatly perplexed our correspondents. The bark was punctured at intervals, and on removing it the inner bark and the wood was found to be marked by channels, the branch channels branching off at nearly right angles from the main passage. Although it is not a common occurrence for apple trees growing in this country to be injured in this way, we had no difficulty in recognising the injury as the work of the small bark beetle (*Scolytus hæmorrhous*), which appears to be very troublesome on the European continent and in the United States. The full-grown beetle is about an eighth of an inch long, and russety black in colour. Towards the end of April, or quite early in May, the beetle emerges from the pupa case, and in a very short period it commences to take the steps necessary to ensure the perpetuation of the species. In the first place it bores a hole in the bark of the smaller branches, and forms a passage on the inner side about three-quarters of an inch in length. This task having been accomplished, the eggs, which are whitish, are deposited somewhat regularly on either side, and in a few days the larvæ are hatched, and commence to form channels at right angles to the main passage, chiefly between the bark and wood, but in the case of soft shoots the channels are frequently made through the soft wood. At the end of the channels the grub forms a small receptacle in which it ensconces itself and changes into a chrysalis. After passing through the chrysalis stage the beetle escapes by boring through the bark, and within a very short period commences to deposit its eggs. Two generations of the small bark beetle are produced in the course of the year, and consequently it increases at a somewhat rapid rate where the conditions are favourable to its reproduction. The beetle has the greatest preference for trees that are in a more or less unsatisfactory state of health, and, recognising this fact, American cultivators recommend that when an orchard is badly infested to ring one of the trees, which from some cause may be considered of but little value, to cause it to become unhealthy, and act as traps for the beetles. The ringing is done early in the spring, and the trees are cut down in June and burned, it being, of course, important to perform this operation before the beetles attain full development and escape. Infestation of the trees by this pest is indicated by the ends of the young shoots dying away and the shrivelling of the leaves; and in the case of trees in small plantations known to be infested, it will be advisable to examine the branches and remove and burn all that are found to be punctured. The attack of the beetle may possibly be warded off by painting the wood with a paraffin emulsion, or some other winter dressing, before the buds begin to swell; but this method can only be recommended when a few trees have to be dealt with, and, speaking generally, the pest can be kept in subjection by cutting off and burning shoots seen to be infested.

AN AUSPICIOUS EVENT.

By a happy coincidence the Rev. H. H. D'ombrain, the founder of the Horticultural Club, will attain his eightieth birthday on the 10th inst., the date of the next monthly meeting of the club, and as he has occupied the position of honorary secretary since the commencement, it has been decided to take advantage of the opportunity for presenting him with a token of the appreciation of his long-continued labours, and of the high esteem in which he is held by all. Mr. Harry J. Veitch, chairman of the club, and Mr. George Munro, of Covent Garden Market, have the matter in hand, and they inform us that, "As it is difficult in so short a time to ascertain what would be most acceptable to him, we suggest that he be presented with a sum in a purse, towards which each member should contribute a guinea, asking him to use it as he and his family should prefer." The suggestion is an exceedingly happy one, and knowing the estimation in which Mr. D'ombrain is held by the members, we are quite sure it will be readily accepted and acted upon. It is somewhat unfortunate there should not be sufficient time to take the steps necessary to raise a testimonial that would bear a more direct relation to the remarkable services that have been rendered by Mr. D'ombrain in the cause of horticulture than is now possible. But we presume the members of the Horticultural Club do not wish to limit the pleasure inseparable from showing in a tangible form their appreciation of Mr. D'ombrain's services, and of his invariable geniality and courtesy; but rather that they will gladly welcome expressions of sympathy with the movement from all who take an interest in floriculturists and horticulturists, whether members of the club or not. To recount Mr. D'ombrain's services that have been so freely rendered during the past half century is not now necessary, as he is well known to all as an active and able worker. But his most conspicuous services have been the founding of the National Rose Society and the Horticultural Club, and the conduct of their affairs as honorary secretary from their foundation, and these alone more than justify the steps that are being taken by Mr. Munro and Mr. Veitch with a view to enable those who appreciate Mr. D'ombrain's work to give practical expression to their feelings on this auspicious occasion.

Calandrinia Tweedi is a new and interesting plant now flowering for the first time in England, in the Alpine House at the Royal Gardens, Kew. The foliage is stout and deep green, and the habit of the plant is dwarf; a specimen might readily be mistaken for a statice when not in flower. The flowers are about two to two and a half inches across, and of a soft salmon-tinted flesh colour; they are starry, and have eight segments. The species is from California, and sent to Kew by Mr. Johnson, Oregon; it is said to be hardy, and the authorities are testing its capabilities as a hardy plant in the rockery. Should it resist our damp winters it is a plant that lovers of hardy and rockery plants will soon desire to possess. The genus Calandrinia belongs to the natural order Portulaceæ.

Chiswick Gardens are now well worth a visit, were it only to see the magnificent display of apple blossom that is unfolding day by day. The pears have been, and in a few cases still are, very beautiful, and not many of the trees have been injured by frost. Plums in the open and peaches and nectarines on the walls will not yield heavy crops this season, but plums on the walls have set freely. The vineries all look well, and the Muscat House in particular is showing some very fine bunches that soon will be flowering. Trials of annuals will be on a most extensive scale this season, and the same may be said of violas, while pæonies, phloxes, irises, carnations, &c., are retained. Large trials of peas, onions, radishes, lettuces, &c., are in hand, and kales will also again be cultivated on a large scale. With regard to the onion trial we may say that the autumn-sown crop has not passed through the winter very successfully.

New Ideas Concerning the Codlin Moth.—Professor Shuderland, of the Cornell Experiment Station, is upsetting our notions of the life history of the Codlin Moth. Instead of laying her eggs in the blossom, he declares that the moth does not appear till a week after the blossoms fall, and then it deposits the eggs upon the side of the apple. In about ten days the maggots are hatched, and they then creep around the apple till they find the calyx, into which they creep between the lobes, which have by this time closed tightly. Up to this period the maggots have not eaten anything; but soon after entering the calyx they begin to gnaw their way into the apple. Hence it is argued that trees should be sprayed with Paris green or some other poisonous wash as soon as the blossom falls, in order that the poison may be deposited in the calyx, where it will be eaten by the maggot. If spraying be delayed ten days or longer, the calyx will have closed over the maggot, and the poison will not reach it.

Curious Mushrooms.—From time to time we receive from our correspondents specimens of the curious freaks in which the common mushroom indulges, and sometimes these are very remarkable. Our readers will remember the triplet mushroom figured in our issue of May 5, 1894, p. 243, which represented a large mushroom with two smaller ones growing from its summit, and in an inverted manner, that is to say, the stems were uppermost. We have now to acknowledge a large specimen from Mr. J. Rendle, gardener to J. A. Hunt, Esq., The Laurels, Enfield; this shows the most common form of freakage seen in mushrooms, viz., an ordinary growth with another mushroom growing from the top of it. Mr. Rendle's specimen is the largest of its kind we have ever seen, as each mushroom measured about four and a half inches across, and the two-storied specimen attained a total height of eight and a half inches.

The Botanical Magazine for the current month is a thin number, for four of the five plates are missing, and cannot be supplied until the issue of the June number owing to a fire at the lithographer's. Amomum hemisphæricum is figured, and is a Javanese plant closely allied to the gingers; other species described are Symphyordra Wanneri, a pretty campanula that is annually seen in good condition both in the Rockery and Alpine House at Kew—the flowers are deep violet blue; Kalanchoe flammea, previously described in our columns, a succulent with heads of yellow and orange flowers; Armeria cæspitosa, a Spanish Thrift, with close heads of rosy flowers; and Stephanandra Tanakæ, a Japanese plant akin to the spiræas, flowers white and yellow, leaves clear yellow in autumn.

Variation in Ferns is a subject with which our able coadjutor, Mr. C. T. Druery, F.L.S., V.M.H., is pre-eminently conversant, and has frequently dealt with in our columns, consequently his discourse at the Horticultural Club on Tuesday next cannot fail to prove both interesting and instructive. Mr. Druery's lecture is on "Nature versus Culture in Fern Variation," and it will be illustrated by Nature-prints by the late Colonel Jones, who was also a great authority upon British ferns.

The Eucalypti, or Gum Trees of Australia are now generally recognised, not only as the giants among trees, and as providing splendid timber, but as possessing medicinal virtues of various kinds, but it is not so generally known that such virtues are shared also by different species of tea tree and wattle. The flowers of the native pittosporum yield a jasmine-like scent by distillation; and the boronia and other rutaceous plants abound in volatile oils. The thorn apple, castor oil plant, pimpernel, American nightshade, fennel, wartwort, and other plants differ very slightly, if at all, from those found in other countries. The castor-oil plant not only yields the well-known oil, but the leaves have been successfully employed as a galactopoietic, for remedying the absence of milk in the maternal breast. The thorn apple is used as a cure for asthma, the seeds, when expressed and made into an ointment with lard, being good for irritable ulcers, burns, and scalds. The American nightshade is useful as a purgative; and the pimpernel is employed in mania and hydrophobia; the juice, when employed to the eye in certain stages of ophthalmia, having the property of cleansing it in a remarkable manner. These Australian native plants known to possess medicinal properties, will, at some future date, have considerable industrial value.

National Rose Society's Conferences.—This society has arranged two conferences for the present year, and the first will be held in the Sydney Gardens, Bath, on Thursday, June 23, when Mr. W. F. Cooling will open a discussion by reading a short paper on "How different kinds of roses should be pruned." The second conference will be held in the grounds of Spring Hall, Halifax, on Thursday, July 14, when Mr. George Paul, V.M.H., will open a discussion by reading a short paper on "Rose Exhibiting." On each occasion the chair will be taken at three p.m.

Manures for Potatos.—The authorities of the University Extension College, Reading, have been investigating the question of applying fertilisers to potatos, and in the conduct of their experiments they have had the co-operation of Mr. Arthur W. Sutton. The results obtained indicate that the potato crop does best on land enriched with the manuring of previous crops; that on such enriched land the direct application of many artificial manures to the potato crop may do harm, especially where there is a comparatively dry soil and climate; that on soils in rather poor condition the crop of potatos can be much increased by the judicious application of artificial manures.

Productive Potatos.—The annual report of the Irish congested districts contains a report on the experiments that were made last year with a view to determine which of the most productive varieties of the potato would be the most suitable for cultivation in conjunction with the Champion, which in many places is almost exclusively grown. Eleven varieties were grown on ninety-seven experimental plots, and of these, nine varieties were grown on all the plots, two on seventy-seven plots, and one variety on twenty plots. The varieties selected were Beauty of Hebron, Up-to-Date, Antrim, Wonder, Beauty of Bute, Garton, Main crop, Irish White, Champion, Ardcairn Beauty, and Snowdrop; and the result shows that the most productive was Up-to-Date. A crop exceeding ten tons per acre was produced in thirty-seven instances by Up-to-Date, in eight instances by

Champion, in seven instances by Irish White, in six instances by Beauty of Bute, in five instances by Antrim and Maincrop, in four instances by Beauty of Hebron, in two by Ardcairn Beauty and Garton, and in one instance only by Wonder. A crop exceeding five tons per acre was yielded in eighty-one instances by Up-to-Date, and in seventy-nine instances by Champion, but the last-named varieties produced crops exceeding four tons and three tons the greatest number of times, and in no case did it yield less than one ton per acre, whereas Up-to-Date failed in one instance to produce that quantity.

Scientific Horticulture will not have advanced much as a result of the findings of the R.H.S. Scientific Committee at its most recent sitting. There were very few specimens to be considered, and only four members present. Some vine leaves were received from Mr. F. M. Gulrin, Iscoed, remarkable for a stickiness. This appeared to be attributable to green fly, although none was present. The exudation is the result of puncture. Mr. F. F. Freeman sent some decayed pæony leaves which appeared to have decayed at the junction with the stem. They were forwarded to Mr. W. G. Smith for examination for the presence of fungi. Mr. Henslow described a rather curious case of a bush of Ribes coccinea growing by the south side of some pailings. It had sent up a number of shoots on the north side. The former half were in full leaf bearing very few racemes; while that on the other side was covered with flowers, the foliage being scarcely apparent.

Tomato Disease Prevention.—The cultivation of tomatos has attained such large proportions, both in private gardens and commercial establishments, that the prevention of fungoid attacks is a matter of primary importance. As in the case of the potato, the tomato is liable to be seriously damaged from diseases caused by fungi. The leaf-blight disease begins by attacking the older or lower leaves first, and then extends upwards to the younger parts of the plants. The injured leaves gradually lose colour and become thickened and curled at the margins. Brown spots next appear, and ultimately the leaves die and fall off, the plant being thus rendered incapable of producing and ripening fruit. Tomato blight may arise from the use of seed from diseased and enfeebled stock. It may be contracted through the agency of spores which linger in the soil in which diseased plants have been grown. Trials conducted at the Maryland experiment station have shown the Bordeaux mixture to be an effectual means of checking the tomato leaf blight. In 1896 spraying with the solution four times resulted, over thirty-five varieties, in an average increase of 2·5 tons per acre of marketable fruit. In 1897 spraying three times resulted, over nineteen varieties, in an average increase of 2·2 tons per acre of marketable tomatos. The increase in crop as an effect of spraying ranged from a quarter of a ton to six tons per acre in 1896, and from a quarter of a ton to 4¼ tons in 1897. Some varieties appear to be more susceptible to blight than others. In 1896, however, all save one variety, and in 1897 all except three varieties, gave an increased crop of ripe fruit as a result of spraying. The *bouillie* employed was made in the proportion of 8 lb. of sulphate of copper and 4 lb. of quicklime to forty or fifsy gallons of water; the mixing is, as we have frequently advised in giving directions for the preparation of the mixture, best done in wooden vessels.

The Exhibition of British-grown Fruit to be held under the auspices of the Royal Horticultural Society, at the Crystal Palace, will take place on September 29 and 30 and October 1. The schedule of this show is now ready, and may be obtained on application to the R.H.S. secretary. The next meeting of the society takes place at the Drill Hall on May 10, when the committees meet as usual, and in the afternoon the Rev. Professor G. Henslow, M.A., V.M.H., will lecture upon "Some of the Plants Exhibited." We understand that this occasion will offer the last opportunity for Fellows to compete for the Veitch prizes offered for the best-flavoured apples and pears.

The French National Chrysanthemum Society.—There is every sign of great activity in the executive of this young but rapidly increasing society. Its journal continues to appear, and contains much matter interesting to Continental and other "mummers," and the society has recently had published in separate form some of the principal papers read at the Orleans Conference last November. The papers form a neatly printed pamphlet of thirty-six pages, with illustrations, and the subjects are as follows: Chrysanthemum maladies and parasites, the fertilisation of the chrysanthemum, and the best manures and composts to be used in chrysanthemum cultivation, the last being from the pen of our friend Mr. Fatzer, who, as an able cultivator, speaks with authority. The society, although only in the third year of its existence, now counts more than four hundred members, and includes the names of most of the famous raisers aud growers in Europe.

Importation of Plants into Greece.—The Board of Agriculture state that they have received through the Foreign Office a translation of a decree, dated January 4, 1898, embodying the measures taken in order to prevent the introduction of phylloxera into Greece. By this decree it is forbidden to import from any country, whether infected with phylloxera or not—(*a*) Any parts of vines, whether fresh or dry; (*b*) any living plants or parts thereof; (*c*) madder and liquorice; (*d*) stakes which have been used to support vines; (*e*) vegetable or mixed manure; or (*f*) vegetable soil and any kind of ships' ballast consisting of pebbles, earth, or mixed sand. Importations, under certain conditions, are only permitted from Belgium, Holland, Denmark, Sweden, and Norway, where phylloxera does not exist. Grafts and cuttings of plants (vines excepted) for agricultural experiment stations may be imported through certain ports after many formalities. The importation of the following articles *inter alia* is, however, permitted, viz., all kinds of dry seeds, dried fruits, and dried medicinal [illegible].

The Commons Preservation Society keeps steadily at work, and does a large amount of good in a quiet way. The Kent and Surrey Committee of the society has just issued its report for 1897, this showing that in the counties concerned fifty-five cases of encroachment have been dealt with in the year. Among the more important cases dealt with were those of the Ham Common and Lammas lands, the Clackett's Path, the Abbey Hill Path (Lamorbey), the New Eltham roadside waste, the Chelsfield Path, the Oak of Honor Hill, the Herne Hill right-of-way obstruction, the Field Hedges Lane (Frimley), the Mariners Path (Crockham Hill), the St. Martha's Path (Guildford), the Horsell Common (Woking), the Tunbridge Wells footpath case, and the Coxhill Green (Chobham). The committee complains that owing to local apathy it experiences great difficulty in obtaining necessary support and information, consequently it is anxious to found local branches at all important centres in Kent and Surrey.

New Zealand Apples will not be sent to this country this season, owing to a rupture between the fruit growers and the Colonial government. The Government guaranteed one penny per pound as a minimum, and at this rate a number of growers were willing to ship fruit. Later, however, the Agricultural department made a condition that shippers should advance five shillings per case to cover expenses, beside payments of other kinds, and make their own arrangements as to consignment. The Auckland Fruit Growers' Association took the lead in breaking off negotiations with the Government after these radical alterations of conditions.

An Italian National Chrysanthemum Society.—We are informed that a few amateurs and others interested in the chrysanthemum have formed a provisional committee for the purpose of organising a national society in Italy. Among the names we notice those of our friend Mr. Briscoe-Ironside, Mr. Scalarandis, and others. The lines upon which the new society is to be established are somewhat similar to those of the French N.C.S., and include the promoting of shows in various parts of the country, the publication of a monthly journal, and the granting of medals, diplomas, and subsidies. A preliminary circular has been issued, and as soon as a sufficient number of applications has been received is is expected that the society will take a definite form Mr. Paolo Radaelli, of Milan, is the provisional secretary.

Fruit Cultivation at Las Palmas is beset with not a few difficulties, though with capital, requisite knowledge, and perseverance, these may be overcome. The business is not all pleasure and profit, and Vice-Consul Ferguson does not encourage emigrants. He states that people who want to conduct a fruit business in Las Palmas must have a perfect knowledge of the English market and its requirements, where to, whom to, and how to send their produce home, and, most important, when to send it and when to throw it away. They must be prepared to enter into contracts to sell the whole produce of a given standard of size and quality that the contracted land produces at a stipulated price per one hundred pounds in the case of tomatos and potatos, and at per bunch of so many "hands" in bananas. That means they must have the necessary capital, so that in a dry season, such as last year, when, owing to no rain having fallen, the heat, and concurrent causes, they can afford to take and handle all the fruits, which, unfortunately, ripen and come forward at the same time, making the balance of the home market go wrong, and themselves too if not strong enough to tide it over. In other years the *maleza*, a kind of mildew, will be prevalent, and they will lose all the fruit they have counted on having to ship. The business has large profits when things go right, and, provided the possession of sufficient capital, local knowledge of English markets, good administrative ability to deal with the Spanish fruit-grower, packer, and peon, bodily strength enough to endure long riding in the saddle, under a hot sun, over mule tracks between different villages, and the strain of constant day and night work when a ship is due home, then let them go into the business, and they will prosper; otherwise the best advice is, Don't. The climate is equable, for the tropical heat is moderated by the Atlantic breezes. Winter is almost unknown on the coasts. The east and south-east winds are the scourge of this island. Blowing over the burning plains of Africa, they carry an intensely hot and dry air, which destroys vegetation, and induces disease. The absence of severe cold makes it a pleasing retreat for invalids, and the slight variation of temperature leads many to resort thither. But the very mildness of the atmosphere makes it less attractive to those who prefer a bracing air, and enervating to those engaged in active employment. Then to live as Englishmen live at home, with plenty of fresh meat, is not easy in Las Palmas; land not the least difficulty is the postal arrangements.

Sewage Farming at Congleton.—Mr. W. Bowler has been conducting a large number of experiments at Congleton with the town sewage as a manurial agent for farm crops. The results confirm what has already been found, viz., that carefully used the sewage is a splendid fertiliser, and will increase the yield of some crops as much as fifty per cent. With regard to wheat production, Mr. Bowler states that the increased yield is produced at a cost of less than 1s. per bushel, and that the expense in sowing, reaping, and threshing was practically the same as for the poorer crop. When we consider, he continues, that London destroys annually what would produce fifty million bushels of wheat, which London could restore to the farmer at a cost of 1s. per bushel for the wheat produced, we are forced to the conclusion that no sin could have been greater against Nature. The farmer cannot help himself in this matter. He is practically asked to produce calico without cotton. His whole duty is to feed the teeming population of our great cities, and he naturally looks to the cities for his necessary raw material in return. They offer him, not bread for his co-workers of Nature, the bacteria of the soil, but stones. What, then, would be the consequence if the vast stores of raw material (the base things of the world, which are despised, and which the insatiable maw of the ocean now swallows) were made accessible to the British farmer? Who can limit the increase of national wealth, national employment, and national home-grown food which would accrue to our country if a true natural method of sewage disposal were established in place of the many tinkering artificial devices by which man's prentice hand has tried in vain to improve on Nature both as regards "artificial" manures and "artificial" methods of sewage dispos

A MORNING MIXTURE.

Diluculo surgere saluberrimum est.

I REGRET to have to announce the indisposition of Peter. For some time past he has lacked his usual sourness, and been affected by sudden bursts of hysterical cheerfulness. This alarming symptom was followed by another equally amazing and grave. I caught him with pencil (a stump one inch long) and paper (a wrinkled sheet permeated with an odour of tobacco) in obscure corners of the garden, making jottings with an air of desperate and awe-inspiring malevolence. A rumour then reached me that he was preparing a column of notes of his own for the GARDENERS' MAGAZINE, in which various "experts" were to receive such a taking down as they have never experienced in the course of their misspent lives. Happily, however, for their repose and reputation, the unwonted effort has exhausted Peter, and he has disappeared, leaving word that he had been ordered a change of air. He may have gone to the Ghent quinquennial, led on by those wonderful illustrations; he may have gone to the wars; he may have gone to select a new site for the Horticultural Hall. The only things which are certain are that he is not here, and that his manuscript is missing also.

On learning the nature of Peter's task, the result of which I awaited with mingled curiosity and trepidation, I had contemplated a brief respite from literary labour. It seemed to me certain that his communication would have been of so fearful and wonderful a nature that readers would have clamoured for a suppression of the Luxian in favour of the Petronian mixture. As it is, I find myself under the unexpected necessity of girding myself for fresh literary labour. Just at the moment I appear to be at peace with the world, whatever dread onslaught may be looming in the future. There has been no second "evening dose" to disturb my dreams. I will take advantage of the lull to speak of a visit to a friend whom I call the orchid oracle, and of a wonderful new form which will soon see the light. The orchid oracle is steeped to the eyebrows in orchid lore. He knows every one of the thousands of forms, their habitats if imported, their pedigree if cultivated hybrids. He is a walking encyclopædia of orchid information.

There is more than one orchid oracle in existence, but, like the champion cyclist, he is rare. My oracle stands high amongst his fellows, and when I paid my visit I found him gazing abstractedly at a square enclosure of paper in one of his houses, deep in a day dream. Around were thousands of plants, some spearing through like grass on a new lawn, others large specimens with quaint and wonderful flowers. For the nonce they were all forgotten; his thoughts were absorbed in the precious jewel which was shielded from the vulgar gaze beside him. I knew my man, and let him think on. Before me was a strange cypripedium with flowers of pearl, such as I have never seen gracing Mr. Chamberlain's button-hole in the House of Commons. It was a rare bloom of the Lady's Slipper tribe, with milky sepals and pouch, and tails drooping like frosted wire below. So chaste, so beautiful, so valuable a find must have a marvellous rival indeed, methought, that it cannot win even a thought from the artist whose skill has brought it into being. Presently the oracle awakened. He smiled to himself in silent gratification, then stretched out his hand as though to lift the veil and gaze once more on the goddess beneath; but my voice made him drop it, as though he had a chess-board before him and had been about to make a move that he now perceived would have led him to destruction. He breathed a sigh of relief on seeing me, and I led the conversation to the milky cypripedium so as to let him recover his self-command.

It was a pure white form that he is after, he told me, a Sedeni candidulum, let us say, with sepals, tails and labellum chaste as the driven snow. It will be a treasure that orchidists will gaze on with delight, and the possession of which they will vigorously contest. Orchid journals will announce its birth, committees will sit in consideration upon it, and its price will be as a poor man's annual income—when it comes. Then there is the lipless kind, a paradoxical plant which Nature has produced for the evident purpose of setting hybridists at work to make a lip for it. A cypripedium without a lip! It is as a monkey without a tail, as a donkey without ears! The oracle is worried by such a palpable monstrosity, and so he is crossing it with lipped forms in order to astonish the orchid world with a new work of art.

There is, too, a new cattleya of ivory whiteness, with pink and magenta veinings and tinges of gold, a form of surpassing beauty, and redolent with the delicious odour of honeysuckles. This is another hybridising triumph. Its production, like that of the others, has not been the work of a season. The orchid does not yield up its treasures with the swiftness of a vulgar nasturtium. It develops its growth slowly, advancing, tortoise-like, year by year, building up strange, twisted, gnarled stems and swollen bulbs, until at length the period of probation is passed, the colours are mixed on Nature's palette, and the wondrous flowers gush forth in brilliancy and beauty. It is as the transformation of age into youth, as the change from the dull cocoon into the dazzling, fluttering butterfly, as the metamorphosis for which Faust bartered his soul. But the orchid oracle's task is not a Mephistophelian one. He notes the attributes of this species and that, the beautiful form of one, the perfect colouring of another, and then sets to work to unite their respective qualities in one flower. He cross fertilises with care, sows his seed when ready, watches the little strangers through the tender stages of seedlinghood, waits patiently year after year as they develop leaf by leaf, and inch by inch of stem, and then, when the flowering time comes, what is his reward? Sometimes a number of variations that he had never anticipated, a family of brothers and sisters differing each from each, but none valuable; sometimes one grain in a heap of chaff, one stone that will be worth the polishing, and the rest worthless.

In the orchid oracle's laboratory there are few prizes and many blanks, but his work is absorbing in its interest, and his disappointments are but as clouds beyond which is seen the coming sunshine. What time is lost in raising and cultivating new seedlings which prove to be worthless? There is some acquisition secured, sown perhaps some seven or eight years ago, but watched with all a mother's devotion, season after season, until at length it gives its reward. So we wander amongst them, million on million, house after house densely packed, a priceless collection, with many a pause to admire some choice sort, or to speculate on the prospects of a slowly-developing hybrid. And at length we come back to the tent of paper, where the latest and greatest treasure is hidden away. As yet no outsider's eye had rested upon it; the orchid journals had not announced its birth, nor committees sat in consideration upon it. My friend the oracle was, I could see, going to testify his appreciation of my visit and of our chat by giving me the honour of being the first of the general public to gaze upon his precious bantling.

I saw a noble cattleya, with sepals and petals of richest mauve, glistening and shimmering in the sunlight like the sparkling of distant waters. Its surface was smooth and of silky softness, but there was a ripple-like play of colour upon it, as there is in the phosphorescent coruscations on a moon-bathed sea. No vagrant breath of air moved the satiny petals, yet the play of light on their shining folds gave an appearance of gentle oscillation. In the cavernous recesses of the throat were golden veinings, as though they were paths leading to some cave of treasure trove deep down in the heart of the flower. The lip was a carmine of the intensest depth, with purple shadings added, as though there were not warmth and glow enough without them. Not only was its beauty great, but, as the oracle hastened to point out, it gave its glorious blossoms with a lavish freedom. It was a gem indeed, a pearl of great price, and an amateur had eagerly secured the first claim on it at a price which made me cease the wild, foolish jingling of gold in my trousers pocket, and turn regretfully away.

LUX.

DISA LONGICORNU AND D. MACULATA.

WAS there as much evidence in the tubers of the Cape disas as there is in some plants to indicate their requirements, no doubt more success would have been attained in their cultivation by persons with a wide knowledge of plant culture. Could they see the hard, wiry leaves and stem of the blue disas mentioned in my last note, and the soft, ordinary-fleshed ones of the two above-named species, they would at once conclude there must be a difference of treatment to ensure success with each. Probably it may have been observed that the tubers of some are covered with a soft wool, as it were, while others are quite bare and smooth. The extent to which this is developed seems to be in proportion to the dryness of their habitats; and were its parts properly examined doubtless they would be found similar in structure to "root-hairs," and so be the means of obtaining the greatest amount from a very small supply of moisture.

However, be that as it may, Disa longicornu and D. maculata are very different to the others, both in appearance and the conditions under which they are found in a wild state. They are also more rare and [illegible] in their distribution, D. longicornu being confined to Table Mountain and D. maculata to the Muizenberg and Hottentots' Holland Mountains. The flowers of both are of the same exquisite shade of blue, with the hood more or less distinctly veined with green. D. longicornu is readily known from D. maculata by the broader radical leaves and shorter stem, with a much larger flower and a hood terminating in a blunt spur from one and a half to two inches long. D. maculata has more attenuated leaves and stem, and only a blunt projection, scarcely sufficiently developed to be called a spur, to the hood. The whole plant is seldom more than nine inches in length, being about three inches longer than D. longicornu. The colour, combined with a dwarf elegant habit, should make them great favourites with lovers of this class of orchids.

During November, when in flower, the clumps of D. maculata on the ledges or in the crevices of perpendicular rocks are very effective. Viewed from below, with the clear sky overhead, the flowers are almost imperceptible; but in a side view, with the rocks for a background, the elegant poise of the sky-blue flowers on slender ascending scapes is [illegible] to advantage, and creates in one a vain desire to transport them [illegible] to where their unique charms would be greatly appreciated. In December and January D. longicornu, like a sapphire on an elaborate setting embossed with emeralds, is occasionally found studding the face of rocks draped with the lovely filmy Hymenophyllum rarum or the common H. tunbridgense. The well-known partiality of these associates determine at once the amount of percolating moisture that must be present for a greater part of the year. Yet from January to April or May there is a deficiency of moisture, debarring the tubers from retaining the freshness of those with a constant supply, and during which time the disa obtains its necessary rest. The little sun they could possibly obtain would be early in the day, as both disas are only found on the shady or southern side of rocks, usually at the base of the steep banks of wide ravines.

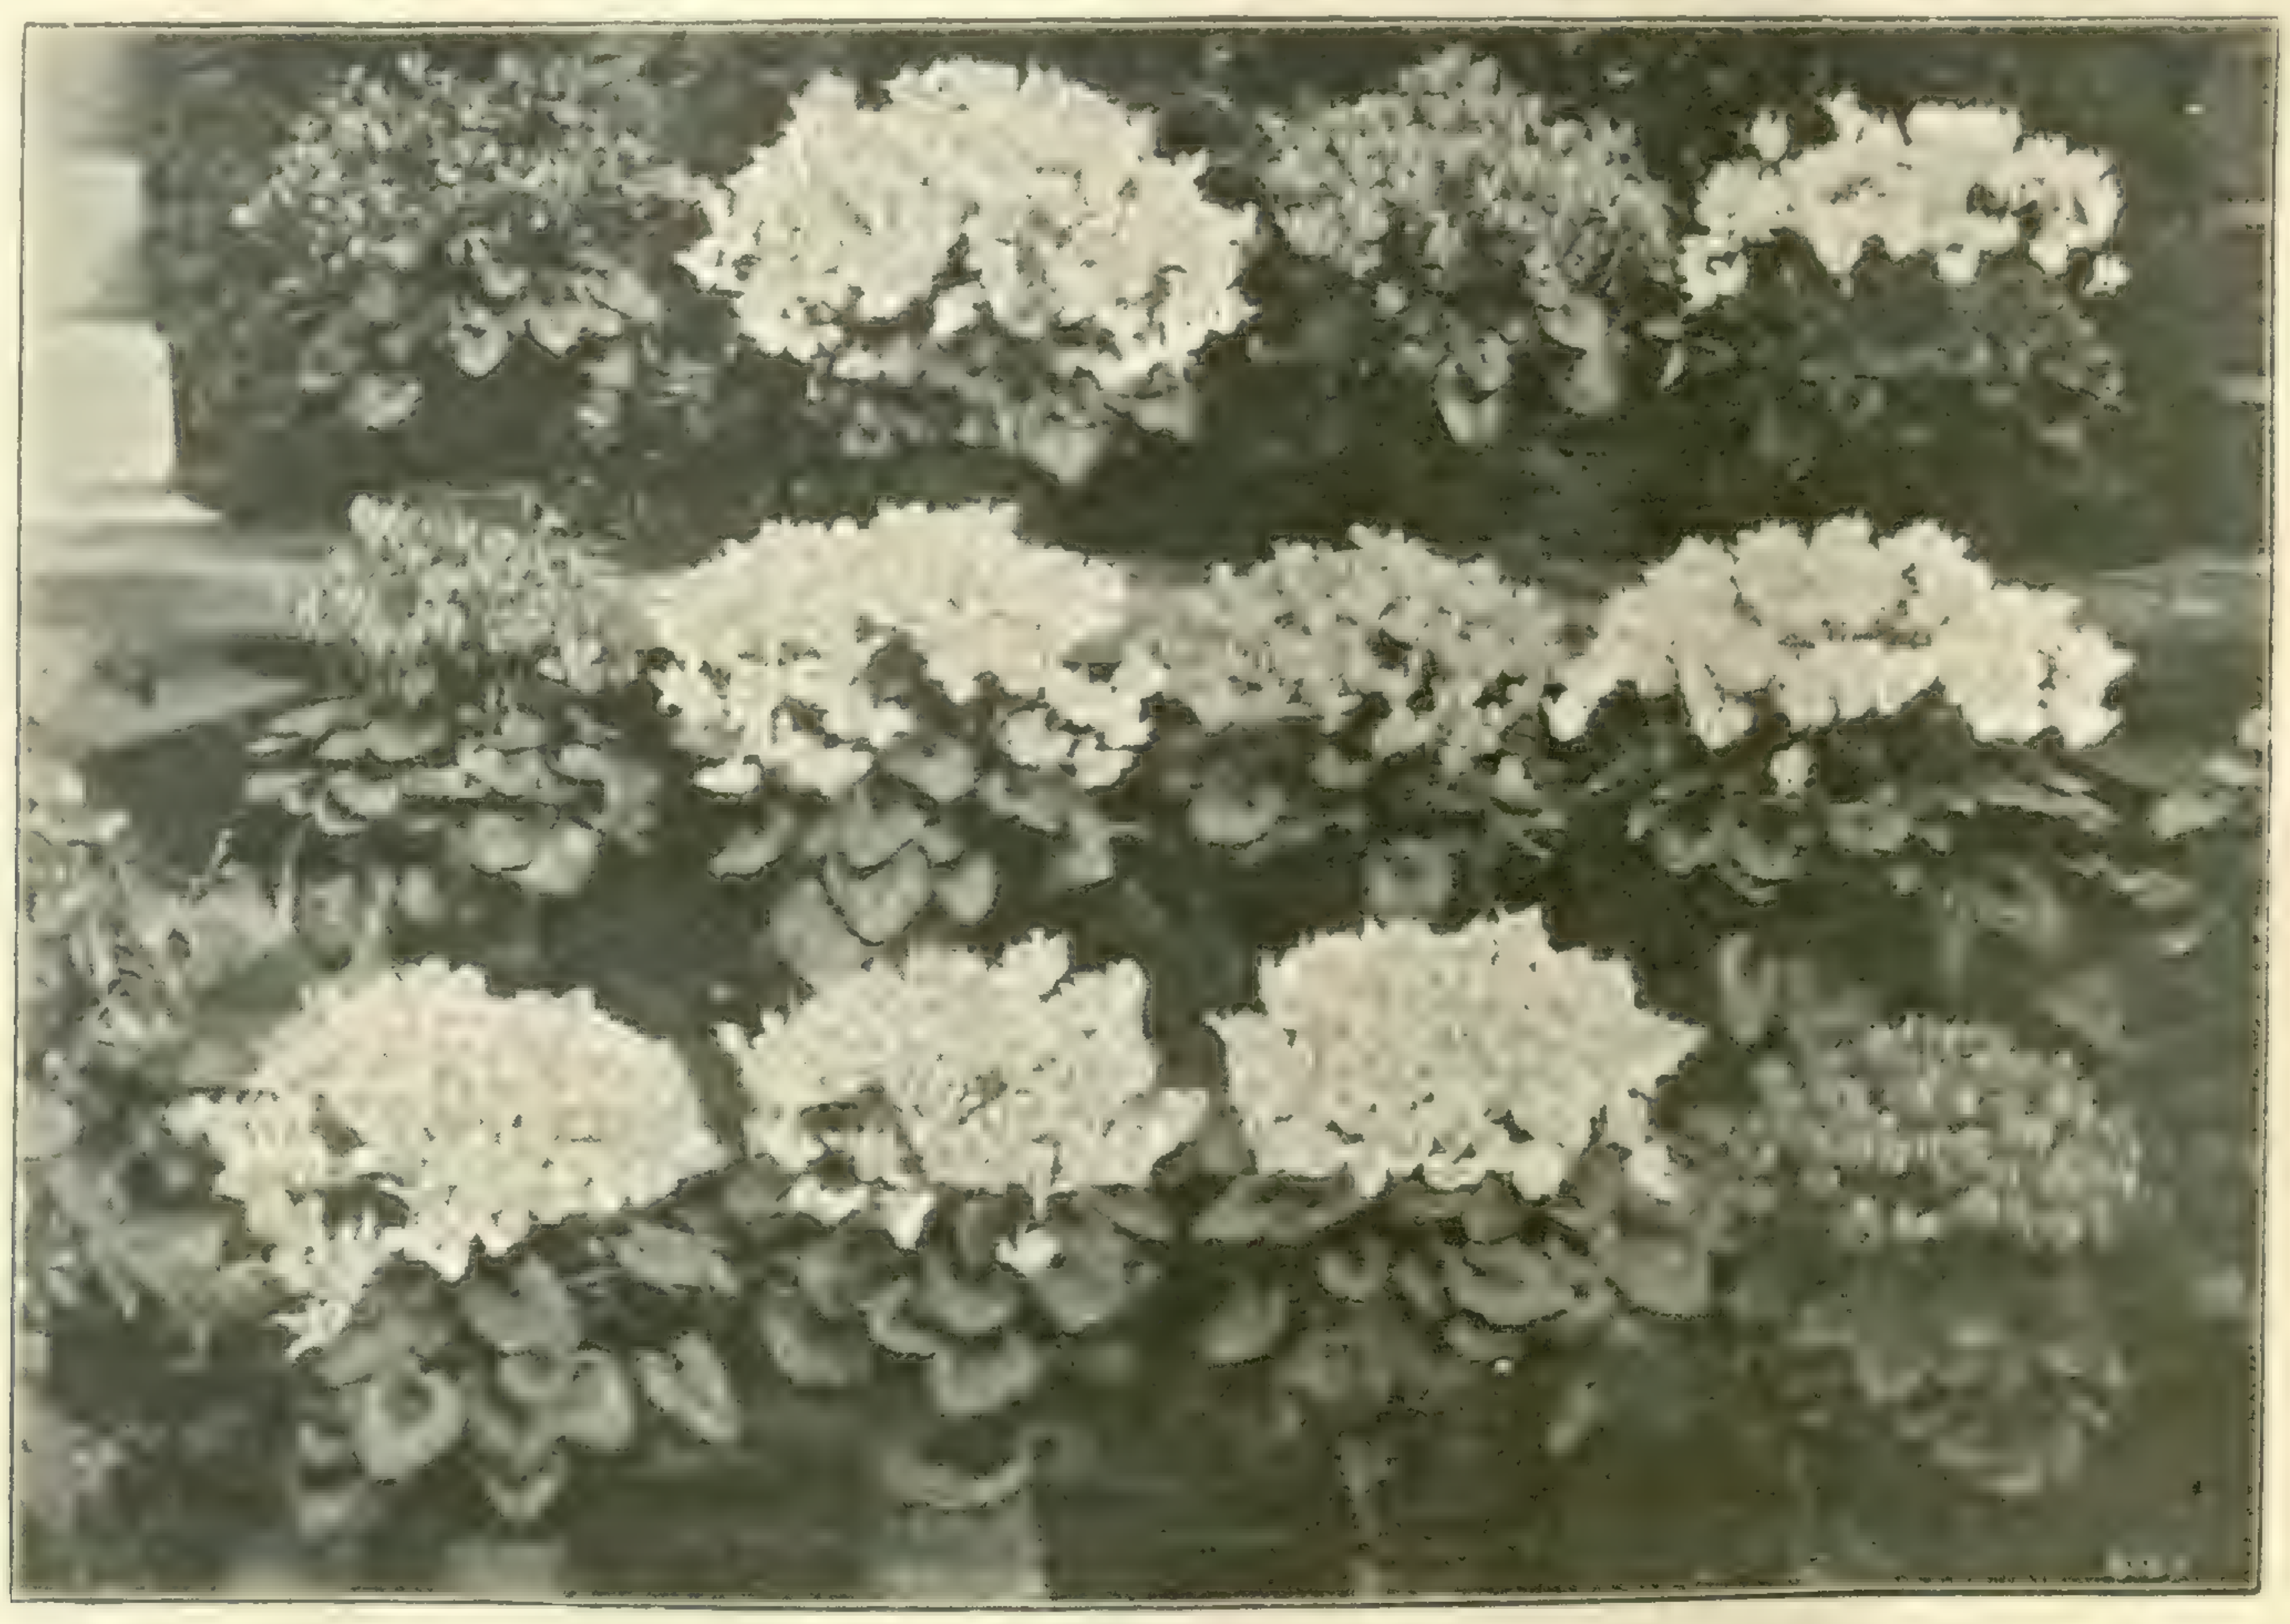
The treatment to ensure success would seem to be that usually given to similar tuberous plants. That is, an abundance of fresh water up to the flowering stage, then gradually diminishing the supply as the flowers wither, until they are at perfect rest, when a shelf in the intermediate house would be an ideal place for them. The soil should be an open fibrous peat, perhaps more spongy for D. longicornu than for D. maculata, which has also a longer rest commencing in December. In their habitats they obtain all possible light without direct sunshine. And we can scarcely think the perpendicular position would be essential to their well-being.

J. W. MATHEWS

Cape Town.

CYCLAMEN AT KEIR.

WE have on previous occasions illustrated in these columns some fine examples of cyclamen cultivated in various parts of England, and showing a very high degree of excellence. We now have the pleasure of presenting to our readers an illustration of twelve specimens of cyclamen grown beyond the Tweed. These are the pick of a splendid collection cultivated by Mr. T. Lunt, gardener to A. Stirling, Esq., at Keir, Dunblane, Perthshire. Mr. Lunt has for a long number of years been widely known as a first-rate cyclamen grower, and as an exhibitor he has been almost as widely respected by competitors, A reference to the illustration will serve to prove that Mr. Lunt is not easily beaten with these useful winter and spring flowers, and that the foliage on his plants is strong and healthy, thus forming a splendid setting for the wonderful quantities of large substantial flowers above.



CYCLAMEN AT KEIR, PERTHSHIRE.

MARIE LOUISE VIOLETS.

THE cultivator of these charming violets who has not the convenience for rooting his stock in frames previous to planting, should split up his plants during the present month. When runners have been suppressed the crowns multiply, so that when divided these are each provided with a fair share of roots. Such divisions are planted straight away into a piece of good ground where they are encouraged as much as possible all through the summer. The aim is to prevent the formation of runners and to develop stout crowns and strong leaves. Partial shade during the greatest heat of summer should be afforded. In September these plants are lifted and placed in brick pits that face south; by planting at this time, and giving a little extra care for a week or so, the plants become thoroughly established when dull November arrives.

Marie Louise violets planted later than September almost always collapse during a long spell of dull weather. Water must be carefully given in winter, and it is safest to err on the side of drought. All runners must be kept pinched off, and also all small leaves and decayed foliage, so that damp is not harboured and rot prevented. When thoroughly established these violets should not need water during December, January, and February, unless the weather be exceptionally bright. About fifty well-grown plants are sufficient for a pit the size of an ordinary two-light cucumber frame.

Marie Louise violets, if rooted early, do very well out of doors in partially shaded places, giving a crop of flowers during autumn, and another in the spring, provided they pass the winter safely. They can also be cultivated in pots or boxes, and in the former they are useful for standing in rooms, when in flower; forcing they object to, and if subjected to heat, quickly dwindle away and become infested with aphis. The cold pit is the best place for the cultivation of Marie Louise violets, and if well rooted, placed near the glass, carefully wired and watered, they will repay the trouble taken.

A DORSETSHIRE GROWER.

Forcing Strawberries.—I was very pleased to note that Mr. Wythes finds La Grosse Sucree such a valuable forcing strawberry. That, too, is my experience, and especially from its very free setting qualities when under difficulties. It happens each year that one or two of our batches have to occupy positions when in bloom that prevent anything like a good set on moist varieties, but La Grosse Sucree rises superior to the position and sets really well, and for that reason I work on a batch or two to come in to meet the difficulty. The natural habit of the plant, which is to make one crown only, and that a good one, on young plants is all in its favour, and it forces really well in five-inch pots; indeed, it is my practice to use no other size for it. Taking it altogether it is really the best of all varieties tor those who have to force their strawberries under the difficulties found in houses where the occupants are of a mixed nature.—J. C. TALLACK.

THE EAST LOTHIAN STOCK.

THOUGH coming somewhat late in the season for my remarks anent East Lothian stocks to be adopted generally, there may be some which may yet be practically followed up with advantage. It is a remarkable fact, though true, that seldom in the southern counties are these stocks seen in the same perfection as in the cooler temperatures of the northern and western counties. This defect is generally attributed to the excessive heat, and accompanying arid conditions so detrimental to vegetation; and, while agreeing that climatic circumstances exercise some influence over their growth, I am of opinion that we are in a greater measure responsible, and that the lack of practical knowledge of the requirements of this most useful subject, or the failure to exercise such knowledge, is the rock on which our hopes perish. I am justified in making this assertion, after having given the matter careful consideration, and in repeated trials, now extending over several years, I have been able to produce crops of superb flowers, as rich in colour as those seen in Scotland—the home of the subject under notice; though I must admit the season was proportionately shorter. Especially was this so in the tropical summer of 1893.

For seed sowing I find from about the middle to the end of January is a good time. The seed is sown in the ordinary way, in pans or boxes, covering them over with about an eighth of an inch of finely-sifted soil. The pans are placed in a vinery at work, which at that season has an average temperature of 60 degrees. As soon as the young stock is fairly through the ground a change into a cooler and dryer house is essential, as at this stage the plants are liable to "damp off"—a gardening expression descriptive of a condition brought about by an over accumulation of moisture. Directly the third leaf is formed the seedlings are subjected to a necessary process, viz., pricked out—*i.e.*, transplanted into quarters in which the tiny plants are afforded space for subsequent development.

Strong cutting boxes are here requisitioned, and I find those prepared from three-quarter inch deal, and made into the following sizes are most suitable, twenty-four by sixteen by four inches; the depth should be still made shallower by having a liberal quantity of drainage placed over the bottom, over which is again placed a layer of well-rotted dung. The soil we use is composed of loam two parts, and one each of mushroom-bed compost, sand, leaf soil, and a dash of soot, and the whole, when well mixed, is fairly well pressed into the boxes. About two and a half inches either way is allowed in pricking off, and this gives ample room. A nice growing temperature is again of considerable advantage, but water must be very carefully and sparingly applied until growth is active; a peach house having a comparative shade is an excellent site at this stage, and then the plants are gradually inured to cooler quarters as they gain size and strength, until about the end of March a frame in which frost is excluded only may be utilised; here the lights must be kept close for a few days, by which time the plants will have taken to their new quarters.

About the middle of April the final planting takes place, and a word as to the preparation of the soil may not be out of place. During the winter months the ground is trenched deeply and a liberal coating of manure placed at the bottom. I use cow manure on account of the lightness of our subsoil, and consequent drought in the hot summer months. The surface is left quite rough that the frost may the better penetrate the staple. In March the whole is deeply forked over, turning it well up. This stage affords opportunity for applying a dusting of soot and dissolved bones, or any of the much-advertised special manures may advantageously be applied. In planting, the plants are placed eighteen inches either way, made firm, and afforded a good soaking should the ground be dry and no immediate prospects of rain apparent; it is always advisable to pot up a few dozens of plants to take the place of any showing single flowers. Water in very dry weather is given once weekly.

Roehampton. J. F. MCLEOD.

MECONOPSIS WALLICHI.

THE Himalayan Poppy is one of the most attractive of hardy biennials, but it is not often met with in gardens; indeed, there are few places where it is grown in any quantity save at nurseries, where hardy plants receive special attention. It is very effective in masses or clumps, and we have grown it for several years in this way. The plants usually attain a height of from five to six feet, with stems as thick at the base as a man's wrist, and they begin to expand their blooms about July, continuing till September. The flowers do not open altogether, but at short intervals, commencing at the top of the stem and continuing downwards, each bloom is cup-shaped, and of a most pleasing shade of pale blue. The foliage of Meconopsis Wallichi is of a very light shade of green and harmonises with the flowers.

The position for the Himalayan Poppy should be a shady one, and sheltered from heavy winds and gales which are most injurious to them. In preparing a bed for them the natural soil should be dug out to the depth of eighteen inches, and if there is not sufficient drainage a little may be added. Then fill the hole up with a compost consisting of half each of boggy peat and rough leaf soil, coarse sand, and a little old chrysanthemum soil should be added, when the bed will be ready for receiving the plants. The early spring and autumn are the best times for planting. When in flower this meconopsis is a great attraction to bees, which pay great attention to it after a shower of rain has fallen on the blooms. Gathering the seed is of great importance; the capsules should be watched every day during September, and when they open at the top, and the seed is seen to be of a dark colour, it is quite time to gather, store in shallow boxes, and place on a greenhouse shelf in the sun for a few days, when the seeds will fall out of the capsules and be ready for passing through a hair sieve to clean them previous to sowing.

Germination is rather a difficult matter. New seed is the best, as that a year or so old seems to have lost its vitality. Indeed, I am quite convinced that with all hardy plants if new seed was more used there would not be so many failures. My method for sowing Meconopsis Wallichi is to procure a clean five-inch pot and put in it about two inches of drainage; over this some rough leaves or soil to keep the finer compost from washing down; fill up with sifted leaf mould and old potting soil with plenty of sand. Give the soil a good watering with boiling water to kill any insects that may be in it, and when it is cool it will be ready for the seed. This should be distributed evenly over the surface, pressed into the soil, and covered very slightly with the same compost. Cover the pot with a piece of brown paper and a small square of glass, transferring the pot to the propagating frame where a temperature of 75 degrees bottom heat can be maintained; a hotbed is even better than the former, as the atmosphere is not so apt to become dry. Plunge the pot, and seedlings should appear in about sixteen days from sowing; keep the sun from these at all times during the seedling stage, and do not allow them to suffer for want of water. A good position for the seedlings is a greenhouse, from whence, after a few weeks, they should be removed to a cold frame and kept near the glass. Slugs are very fond of the seedlings and must be guarded against. When they are fit for handling it is wiser to prick off the tiny plants into light sandy soil in pans. When large enough they should be potted into three-inch pots, using a coarser compost; from such pots they can be planted out where they are to flower.

Meconopsis nepalensis is also a pleasing species with bright yellow flowers that expand a little earlier than those of Wallichi. I find the end or the beginning of the year the best times for sowing the seed, as then there is a longer season of growth before planting time. I have now a nice batch of M. Wallichi, which was raised from seed sown in January this year, and will soon be ready for pricking off into pans.

Totley Hall Gardens. T. W. BIRKINSHAW.

STARVING OLD TREES.

EXPERIENCED cultivators have long been familiar with the facts you so forcibly urged on your readers recently. Could the trees be heard their cry would be for something much more, and better, to eat as well as drink. As I used to tell my hearers when lecturing on Horticulture in East Anglia, we are all familiar with the saying, "All work and no play makes Jack a dull boy." But it is equally or more true that all out and nothing in must end in making garden, orchard, park or street trees—lean, poor, worthless. I once asked a fruit grower who was grumbling loudly as to the miserable state and profits of his orchard, if he had kept any record of the many tons of fruit he had gathered during the forty years he had held it, and how much he had given the trees to eat during that long period. He confessed that he had kept no record of the former, and as to feeding the trees, so far as he knew they had had nothing. Nor had he ever heard of trees eating or drinking like Christians, or horses, or bullocks before, and he evidently thought he had the best of the argument. The feeding and planting of trees is one of those things they do much better abroad than at home. In Paris and other foreign towns each tree may be said to have its own feeding trough and drinking fountain, and both are kept more or less full of good things. Air is also admitted to the roots through open spaces or iron gratings, and this air enables the food, water, and manure to be absorbed and assimilated, and the overhead watering of trees abroad on the eve of sultry days is among the more refreshing sights and sounds to Britishers. Were all our mayors and a few leading councillors to see for themselves our present methods of thrusting tree roots down among a hard and huge network of water, gas, and sewage pipes, and then sealing out all the feeding, genial influences of earth and sky by an impervious, impenetrable layer of concrete, some good might be done. Under such cruel environments the marvel is less that so many trees languish and die than that any live.

D. T. F.

THE TWOFOLD PRODUCTION OF PLANTS.

A TREE, properly so-called, is not a single individual, but is an actual tribe or association of families springing from the parent trunk; closely associated with each other in collateral contiguity and compact union within one stem; yet each preserving a distinct separateness of vascularity, living principle, nutrition, growth, productivity, and subsistence. It is now generally taught that every bud is a distinct offspring of the tree or branch from which it protrudes. [?] When it has come forth into life and form, it pushes its own vessels downwards, inside the parental bark or rind, to the earth, from which they then begin to draw a separate nourishment adapted to promote their development. [?] This they forthwith proceed to transmit to the newly-born shoot, and thereby enable it to expand into foliage and general enlargement. This produces also latent roots which descend into the earth and become the fibre of the wood. Professor Burnett says that every bud should be considered as a distinct individual, containing, at least virtually, roots, leaves, and flowers.

So we find that every ramification of buds, from itself, are so many new individual descendants of the general parent trunk, and the whole tree thus becomes and exists in the state of a large society, or affiliated tribe of distinct individuals, intimately associated together. Hence it follows that all trees and some flowers may be planted by slips or cuttings. For example, the mulberry tree has been raised by planting so large a branch in the spring that the same bore fruit in the summer of the year following. The late Mr. Jaquelin relates that in his garden on one occasion some dahlia branches were broken off by the wind. He placed them in the ground desiring to secure the leaves. In this he did not succeed, but the plants lived and were after a time found to be furnished with tubercles. Here was a new means of multiplication. So we see that branches or cuttings often grow into all their functional organs, and have their principle of life as fully within them as the newborn young of any animal. It appears also that plants produce either shoots or flowers, according as the circumstances under which they are situated lead them. After a long production of shoots without flowers, a vegetable has, when its nutriment, from neglect, has become insufficient for its ramifying elongation, suddenly disclosed its floral organs; and in this way prepared for an offspring by its seeds, when prevented from perpetuating itself by branches; thus evincing that it had received the power of varying its mode of organic reproduction according to the immediate expediency.

Solandra grandiflora, a West Indian shrub, was for many years cultivated in our stove houses and propagated extensively by cuttings. Each plant grew many feet in every season, but these showed no signs of prolification. Left accidentally without water in the stove house at Kew Gardens, the luxuriant growth of its branches was checked, and a flower, for the first time, came into blossom at the extremity of each. Similar treatment has often since produced like results. We see this same principle in the fact that when plants are checked in their growth by cold and frost one effect is to force them prematurely into bloom. This proves conclusively that plants have a twofold mode of perpetuating their species, viz., by branching or by seed. Each is equally effectual, for every new twig is the embryo of a new tree. In the one case the tree completes its offspring within itself, in the other it makes it ready to be subsequently completed, leaving it to undergo first another process—that of hatching in the egg and of germinating in the seed, before the new comer is perfected. All trees have this double power and can exert it. They make new leaves and twigs when not forming flowers and fruit. It is from this action that when a plant luxuriates in foliage it forms fewer flowers. This stops the producing energy from bringing forth shoots and to use its other faculty in producing flowers. Much nourishment results in giving too much vigour for the floral process, but induces ramifications and leaves. With less food it employs itself in the more delicate and beautiful operation of framing its corolla with the attendent stamens, stigmas, and pollen. This explains the apparent phenomena of floral organs changing into leaves, and of green leaves transmutating into those of the flowers. Only one instance is recorded of petals changing into stamens, which occurred in the black currant, but nothing is more common than the alteration of stamens into petals. It is really indifferent though to the living principle into which the nutrition is converted, as either answer equally well for the purpose. In fact, it is a matter determined by circumstances. If interrupted in the elongating process it resorts to the floral. Interfered with again it returns to its foliage. It forms the stamen as a floral instrument, but if disturbed, makes a corolla or stigma, and forms a stamen at another time, or a leaf perhaps instead. The living principle, it is clear, has the choice of doing either, and would seem to do that which it considers best or easiest to perform. Its law is to multiply, and it religiously follows that law.

WM. NORMAN BROWN.

Cactus Dahlias.—In the garden one of the worst features with many varieties of cactus dahlias is that they fail to throw their flowers well above the foliage, but this is being gradually remedied with the newer varieties, and the failing will no doubt be eventually overcome. The following comprise some of the best varieties: Harry Stredwick, dark crimson-maroon; Starfish, orange-scarlet, good; [illegible] Cycle, ruby red; Keynes' White, good white; Mrs. Wilson Noble, pinkish salmon, free; Mrs. Montefiore, deep crimson scarlet; Fusilier, salmon pink; Matchless, velvety maroon; Mrs. Francis Fell, white, drooping habit; Lady Penzance, sulphur yellow; Gloriosa, bright red, tall grower; Bertha Mawley, cochineal, dwarf and free; Mrs. Barnes, pale primrose, tipped pink; Delicata, soft pink; Harmony, reddish-bronze, yellow centre; Countess of Radnor, delicate salmon; Mrs. Turner, deep yellow. The free-flowering pompon varieties are also very useful for garden decoration and for cutting, the small flowers on long wiry stems being always admirably adapted for the latter purpose.—C. HERRIN, *Dropmore.*

THE BEST GUIDE to the garden for the whole year is the "Gardening Year Book," Price 1s., containing practical articles on the cultivation of Flowers, Fruit, Vegetables, &c. "Gardeners Magazine" Office, 4, Ave Maria Lane, London.—[ADVT.]

VEGETABLES FOR EXHIBITION.

RHUBARB.

FEW kitchen garden crops give better returns for high cultivation, and few are more remunerative than rhubarb. It answers well when forced, and it is highly prized in most households for Christmas, and until green gooseberries are ready for use. It revels in a rich, light, sandy loam, but any highly cultivated land will produce it in good quality. It is a deep-rooted plant, consequently the land should be broken up to a good depth. To produce rhubarb of the highest quality, a good open site should be given it, and the ground should be thoroughly trenched, and made very rich with farmyard manure during early autumn to a depth of three feet at least, and the planting should be deferred until the end of February or the first week in March. Nothing is gained by overcrowding, indeed, it is far better to err on the side of liberality of space than otherwise. Four feet from plant to plant is a fair distance, and when more than one row is planted, they should be five feet asunder. Good deep holes should be taken out with the spade, so that the roots are not crippled in planting. The finest of the soil should be carefully worked in, and the crown should be just buried, after which the surface should be mulched with some short stable manure, this being forked in about the second week in April. On no account should any of the stalks be pulled the first season, for the young plants must receive every encouragement to become thoroughly established as soon as possible. Simply cut out any flower heads that may appear, and keep the plantation free from weeds, and this will be all the attention required unless the season should prove a very dry one, and then occasional waterings will greatly benefit the crops.

Early in the autumn, after the growth is completed and has died away, apply a thorough dressing of half-decayed horse manure, which should remain till early spring, when it may be forked in as before advised. If the plants do well good rhubarb should be pulled the second season, but this ought to be done with discretion, as a reasonable amount of growth must be left to allow the plants to build up good crowns for the following year. It is well to keep this always in mind, as it is a common practice to pull rhubarb much too late in the season, and this must considerably weaken the plants for their next production.

Few subjects force more readily than rhubarb if suitable kinds and strong, well-ripened crowns are prepared. Many modes of forcing are practised, but for the earliest supplies by far the easiest and best plan is to lift a few roots each year immediately the growth has died away. For this purpose a small plantation should be grown on a south border, as here the crowns will become thoroughly ripened, and thus answer to early forcing most readily. These plants, after hard forcing, are not worth replanting, so that it is well each year to divide roots and keep up the supply. I know of no more suitable place than the mushroom house for bringing rhubarb forward, but failing this, the forcing house proper; a warm pit, greenhouse, or cellar will answer the purpose. For a succession I much prefer forcing the plants on the ground. Suitable tubs, with the two ends removed, but one end utilised to form a lid, are much to be preferred to rhubarb pots. Just sufficient fermenting material, such as long stable litter and leaves, which will create a sweet gentle heat, should be placed about them, and from well-established roots very large quantities will be produced. It is well to bear in mind that a season of growth must be allowed the plants afterwards, to allow them to recoup themselves before another forcing season; the tubs and forcing material must be removed as soon as the plants show signs of weakness, and the ground forked up and made neat and tidy. On no account should the same roots be forced two seasons in succession. For a further supply previous to pulling outside, tubs should be placed over other roots, but without any fermenting material, and this will afford sticks of excellent quality, and the tubs can be removed very easily from one root to the other, and so the danger of weakening any of the plants to any great extent is considerably lessened. The stock of rhubarb is easily increased either by divisions or seed, but I much prefer the former plan. Anyone, however, wishing to try their hand may easily raise a stock from seed, though these seldom come true to name. The seed should be sown on a warm south border, or better still in a cold frame early in April, and the seedlings should receive every encouragement during the growing season, and be planted out in their permanent quarters the following spring.

Rhubarb is frequently staged in large quantities at many of our summer shows, and enormous sticks are often seen. Like many other productions staged, mere size appears to be the principal aim and practice and this, in my opinion, ought not to be encouraged, as quality should certainly carry most points. The chief points should be high colour, length, and straightness of the stalks, and size, of course, if quality is combined with it. The plants should be thoroughly mulched, and well drenched with liquid manure frequently; that from the farmyard is preferable to all other. The most promising sticks should be selected, and these should be staked carefully to keep them straight, but in such a way that they are not in the least scratched nor bruised. Six sticks are generally exhibited, and they should be as near alike as it is possible to have them. Carefully pull and trim the leaves, leaving about two inches which will improve the appearance of the sticks. Sponge in clean water and neatly tie together with broad pieces of bass.

The varieties I can recommend thoroughly are, Johnston's St. Martin's, very quick and early, and of excellent quality; Royal Albert, a fine old variety, also useful for early work; Myatt's Victoria, though old, is still one of the best; Hawke's Champagne, a fine, highly coloured kind and of good quality; Kershaw's Paragon is a comparatively new introduction, very prolific, and stated never to run to seed. We have grown this somewhat largely during the last five years, and I have never once seen a flower-head on it, which is undoubtedly a great gain. Stott's Monarch is a very large variety, and one of the best for exhibition.

Aldenham House Gardens, Elstree. E. BECKETT.

ACHIMENES.

THESE beautiful gesneraceous plants are invaluable subjects for the decoration of the stove or conservatory, and should commend themselves to all plant growers, for they are easy of culture, and the flowers, which are borne in great profusion, are of diverse and pleasing shades of colour. If the tubers are potted up in two or three successional batches in the spring, the flowering season will be prolonged considerably.

Achimenes make beautiful objects for baskets, for which purpose the colours have a more striking effect if mixed, which may easily be accomplished by dibbling into the moss (with which the basket should be lined) such varieties as the following, which will be found amongst the best for general purposes: A. Ambroise Verschaffelt, A. longiflora major, and its companion, A. longiflora alba, and A. Dazzle. Another very exquisite arrangement may be effected by mixing A. longiflora major and L. alba with A. Sir Treherne Thomas. Other varieties which I consider worthy of cultivation are: A. Aurora, A. Mauve Queen, A. Masterpiece, A. Eclipse, A. Pink Perfection, A. Stella, and A. Williamsi. The varieties enumerated here are all of good habit, being alike suitable either for exhibition or general decoration, the colours varying from pure white, through all the shades of rose, carmine, and crimson, and a few varieties are richly mottled or striped with a deeper colour.

While in a growing state the achimenes luxuriate in a warm and moist atmosphere, but during the flowering season they should be removed to a cooler situation, such as a greenhouse or conservatory provides. The compost I have found admirably suited to the achimenes consists of two parts peat, two parts leaf-soil, and one part each of loam and well-decomposed cow or sheep manure, with a liberal addition of coarse silver sand, the whole to be well mixed and passed through a half-inch sieve. For all ordinary purposes pots will answer well, but for exhibition rather shallow pans are preferable, which should be amply drained, placing over the crocks a good layer of moss, or the rough riddlings from the soil, over which fill in the compost to within two inches of the top; the tubers may then be sown thinly and evenly on the surface, and covered with an inch of soil. Water must be applied judiciously and sparingly until the plants commence to show that growth has actively begun; in fact, at no time must they be over-watered, for I know of no plants more impatient of stagnant moisture at the roots than achimenes. Some cultivators recommend shifting the young plants when two or three inches high. I prefer to plant the tubers where they are to remain, grow, and flower. As soon as they have become established air must be admitted on all favourable occasions, keeping them at all times near to the roof glass. A temperature which suits well to start the tubers ranges from 65 to 75 degrees with sun heat, giving a thin shading during the hottest part of the day. When the plants have attained the height of about six inches, and before they begin to fall about, they should be staked, commencing in the centre with the longest shoot, and gradually insert the others, so that they slope outwards over the rim of the pot or pan; the stakes should be left about a foot beyond the point of the shoot at the time of tying, and frequent attention will be required in keeping them tied from this time until they commence to flower.

Frequent applications of weak manure water will be very beneficial after the plants have become well established, with an occasional watering with soot water; but as the plants begin to show signs of decay, water must be gradually withheld, eventually placing the pans in a dry airy house, that the tubers may be thoroughly ripened before storing for the winter; a position under the staging of a greenhouse will suit them, or failing this, a cellar, the pots or pans being laid on their side and kept quite dry until the time arrives for repotting.

Achimenes increase very rapidly without any artificial propagation, especially when liberally treated, but in the event of the cultivator desiring to increase any particular variety in a short time, the cuttings taken off in the ordinary way and inserted in pots of sandy soil and plunged in the propagating bed will root quite freely.

Stoneleigh. H. T. MARTIN.

Dwarfed Chrysanthemums.—I do not intend to say one word derogatory of the system so ably employed by Mr. Lyne in dwarfing chrysanthemum plants, a method so well expounded on page 246. I would point out, however, that this system has been practised, in perhaps a small degree, to my knowledge, for the last twenty-five years. The editorial allusions made to the plants in November last would lead us to believe this was entirely a new departure. As far back as twenty-two years, however, I remember seeing in St. George's Hall, Liverpool, a group of dwarf plants growing in exceedingly small pots, in fact, some were but sixty size. In each instance the plants carried but one bloom. These, as may be supposed, were all of the incurved section, the Japanese were but few in number in those days. Many times since that period I have grown batches of these dwarf plants, flowering many of them in three-inch pots, merely for the sake of testing the capability of certain varieties, as to the amount of nourishment required to produce blossoms in any form. In the Liverpool districts it is a common practice, in one garden especially, to cultivate these single-stemmed dwarf plants, especially the new varieties, not only for the sake of their flowers, but to enable the cultivator to obtain a full supply of sturdy cuttings in the succeeding autumn, as it is well known, as Mr Lyne points out, that young plants in smaller pots that have not been subjected to so much excessive feeding as the ordinary grown plants, produce cuttings in a more desirable condition. In many of the handsome chrysanthemum groups at the Brighton show, are to be seen specimens of this mode of culture. Four years ago, I noted some wonderful examples of Viviand Morel in the first prize group there. At Windsor, too, can be seen yearly some of these desirable specimens. With the rapid increase in variety in the Japanese section, a wide scope is provided for the cultivation of these dwarf plants. The incurved section does not lend itself so well to this system of culture; at least, for grouping, either in the exhibition room or conservatory, the Japannese varieties are much to be preferred, the graceful habit of unfolding their drooping florets making them general favourites.—E. MOLYNEUX.

MR. ROBERT FENN.

WHENEVER the history of the potato in the nineteenth century, and specially during the long reign of Queen Victoria, is written, scant justice will indeed be done to the subject if it does not include prominent reference to that veteran raiser and grower, of now some seventy-eight years old, the subject of this notice. Born in Suffolk about 1820, Robert Fenn in very early life manifested gardening instincts in a marked way, although he never became what is commonly termed a professional gardener. The mischiefs of childhood wrought with spade and fork became in mature life elements of the most interesting and valuable work; although, after being apprenticed to a London watchmaker, from whose service he ultimately ran away, in sheer detestation of an occupation for which he had no soul, he later took service with one who was at once employer, friend, and companion, for so many years—the Rev. G. W. St. John, then a young man, and recently appointed Vicar of Stanton Lacey, in Shropshire. Here in the vicarage gardens and grounds Mr. Fenn soon found ample room to develop his strong natural taste for gardening, destroying old exhausted trees, replacing them with others, planting here, improving there, and creating much garden interest. Mr. Fenn tells of how here, in the midst of the potatos he then grew so considerably in 1847—Early Morn, Fortyfold, Scotch Regents, Irish Rocks, Farmer's Glory, and others—he was found by the late T. A. Knight, then of Downton Castle, white as a miller with lime, which he was using so freely over the haulm in the hope of checking the spread of what was then so mysterious a disease, or murrain. But smotherings of lime did nothing to check the ravages of the disease, and for many years, especially during cold, wet ones, the potato crops tottered on the verge of decimation.

MR. ROBERT FENN.

So long ago as 1837 Mr. Fenn began experimenting with potatos, raising seedlings, &c., though many years elapsed ere he could show any beneficial results. To Woodstock Rectory the Rev. Mr. St. John was transferred somewhere about 1848, an eventful political year in Europe, and with him went also his *fidus achates*. It was here, too, that Mr. Fenn issued to the gardening papers from time to time those varied series of articles on potatos which attracted so much attention and made "Upwards and Onwards" almost famous. It is impossible to detail the long series of experiments in cross-fertilisation, using for parents the best varieties of the day; but he finally, and after many years' selection, put into commerce Early Market, Rector of Woodstock, Early White Kidney, Bountiful, Red Kidney, and others, all of which had great repute in their day. It was not Mr. Fenn's aim to produce coarse field varieties, but rather those producing tubers of handsome form in good quantity, and of the very best table excellence. But later he found it needful to recognise that there was a demand for heavier croppers, especially for market purposes, and seeing that the American varieties, then in such extreme and excessive demand, were capable of operating in the required direction, he used these both as pollen and seed parents for the production of what became a sort of Anglo-American race. Prior to this, however, he had raised two varieties that were undoubtedly of good size and considerable croppers. These, both from the same seed-ball, were the once universally grown International and the other Woodstock Kidney. The former was the finest and the handsomest of all white kidneys ever raised, but its flesh quality was very undesirable. The latter was, on the other hand, a variety of high table excellence, and handsome, as well as a fair cropper also. But whilst the flowers of International were quite sterile, those of Woodstock Kidney abounded in pollen, hence it became in all directions a most valuable pollen parent for crossing on to the best of the Americans. Using these and other varieties for such inter-crossing, Mr. Fenn raised several batches of seedlings generally of great excellence, and of these two amongst others have invariably shown very high reputations. Sutton Ringleader was one, and the other the beautiful Reading Russet.

After spending many years at Woodstock, where the name of Robert Fenn became a household word, he purchased a pretty rural property, some thirteen acres, quite a small farm, at Sulhampstead, near Reading, where he has been located some twenty-five years. Here, on an excellent stone brash, with ample room and plenty of time to overlook his pets, Mr. Fenn was enabled largely to develop his instincts, and go on crossing the potato. It is an interesting fact, and well worthy of notice, that varieties of potatos raised fully thirty years ago, if not longer, and the stock of which he has preserved and grown annually, are grown with marked success year after year, literally on the same ground at Sulhampstead, and last year the crop was better than ever. So much for potato deterioration. Later years have been occasionally occupied in the effort to raise a new race by intercrossing Solanum maglia with established garden varieties of tuberosum. Nothing of any special value seems to have come from such crosses, and now the latest labours have been directed to intercrossing Solanum Fendleri, a species apparently little used so far in potato production, in Europe at least. The original tubers were sent to Mr. Fenn by his old American friend and correspondent Mr. Pringle, the famous Vermont raiser. Some definite results in small tubers have been obtained, but a few years may have to elapse ere their value or usefulness can be wholly tested. There is, however, no telling what secrets *re* potatos may be hidden in the womb of time, for the advance made in them, and especially in the production of large cropping and disease-resisting varieties has been remarkable. We have had Paterson, Clarke, Finlay, Laxton, and other very successful raisers, but none did so much to create for intercrossing a safe guide and basis, as did the veteran to whom we have been referring. Where he has sown others have been enabled to reap, and that his labours and teachings have not been in vain is evidenced by the fact that the nation is the richer so far as potatos are concerned.

That Robert Fenn may live many years yet is the hope of all his friends. Physically, he is now, in his great age, a far more active and energetic man than are thousands of others not one half his years. He loves the country and all its rural charms; he loves his garden, in which he delights to labour, and his potatos, for which he has all the affection of a loving father. As was earlier said, not a professional gardener, he has all his life been a born or heaven-created one, and is well worthy enrolment in the gallery of garden patriarchs.

A. D.

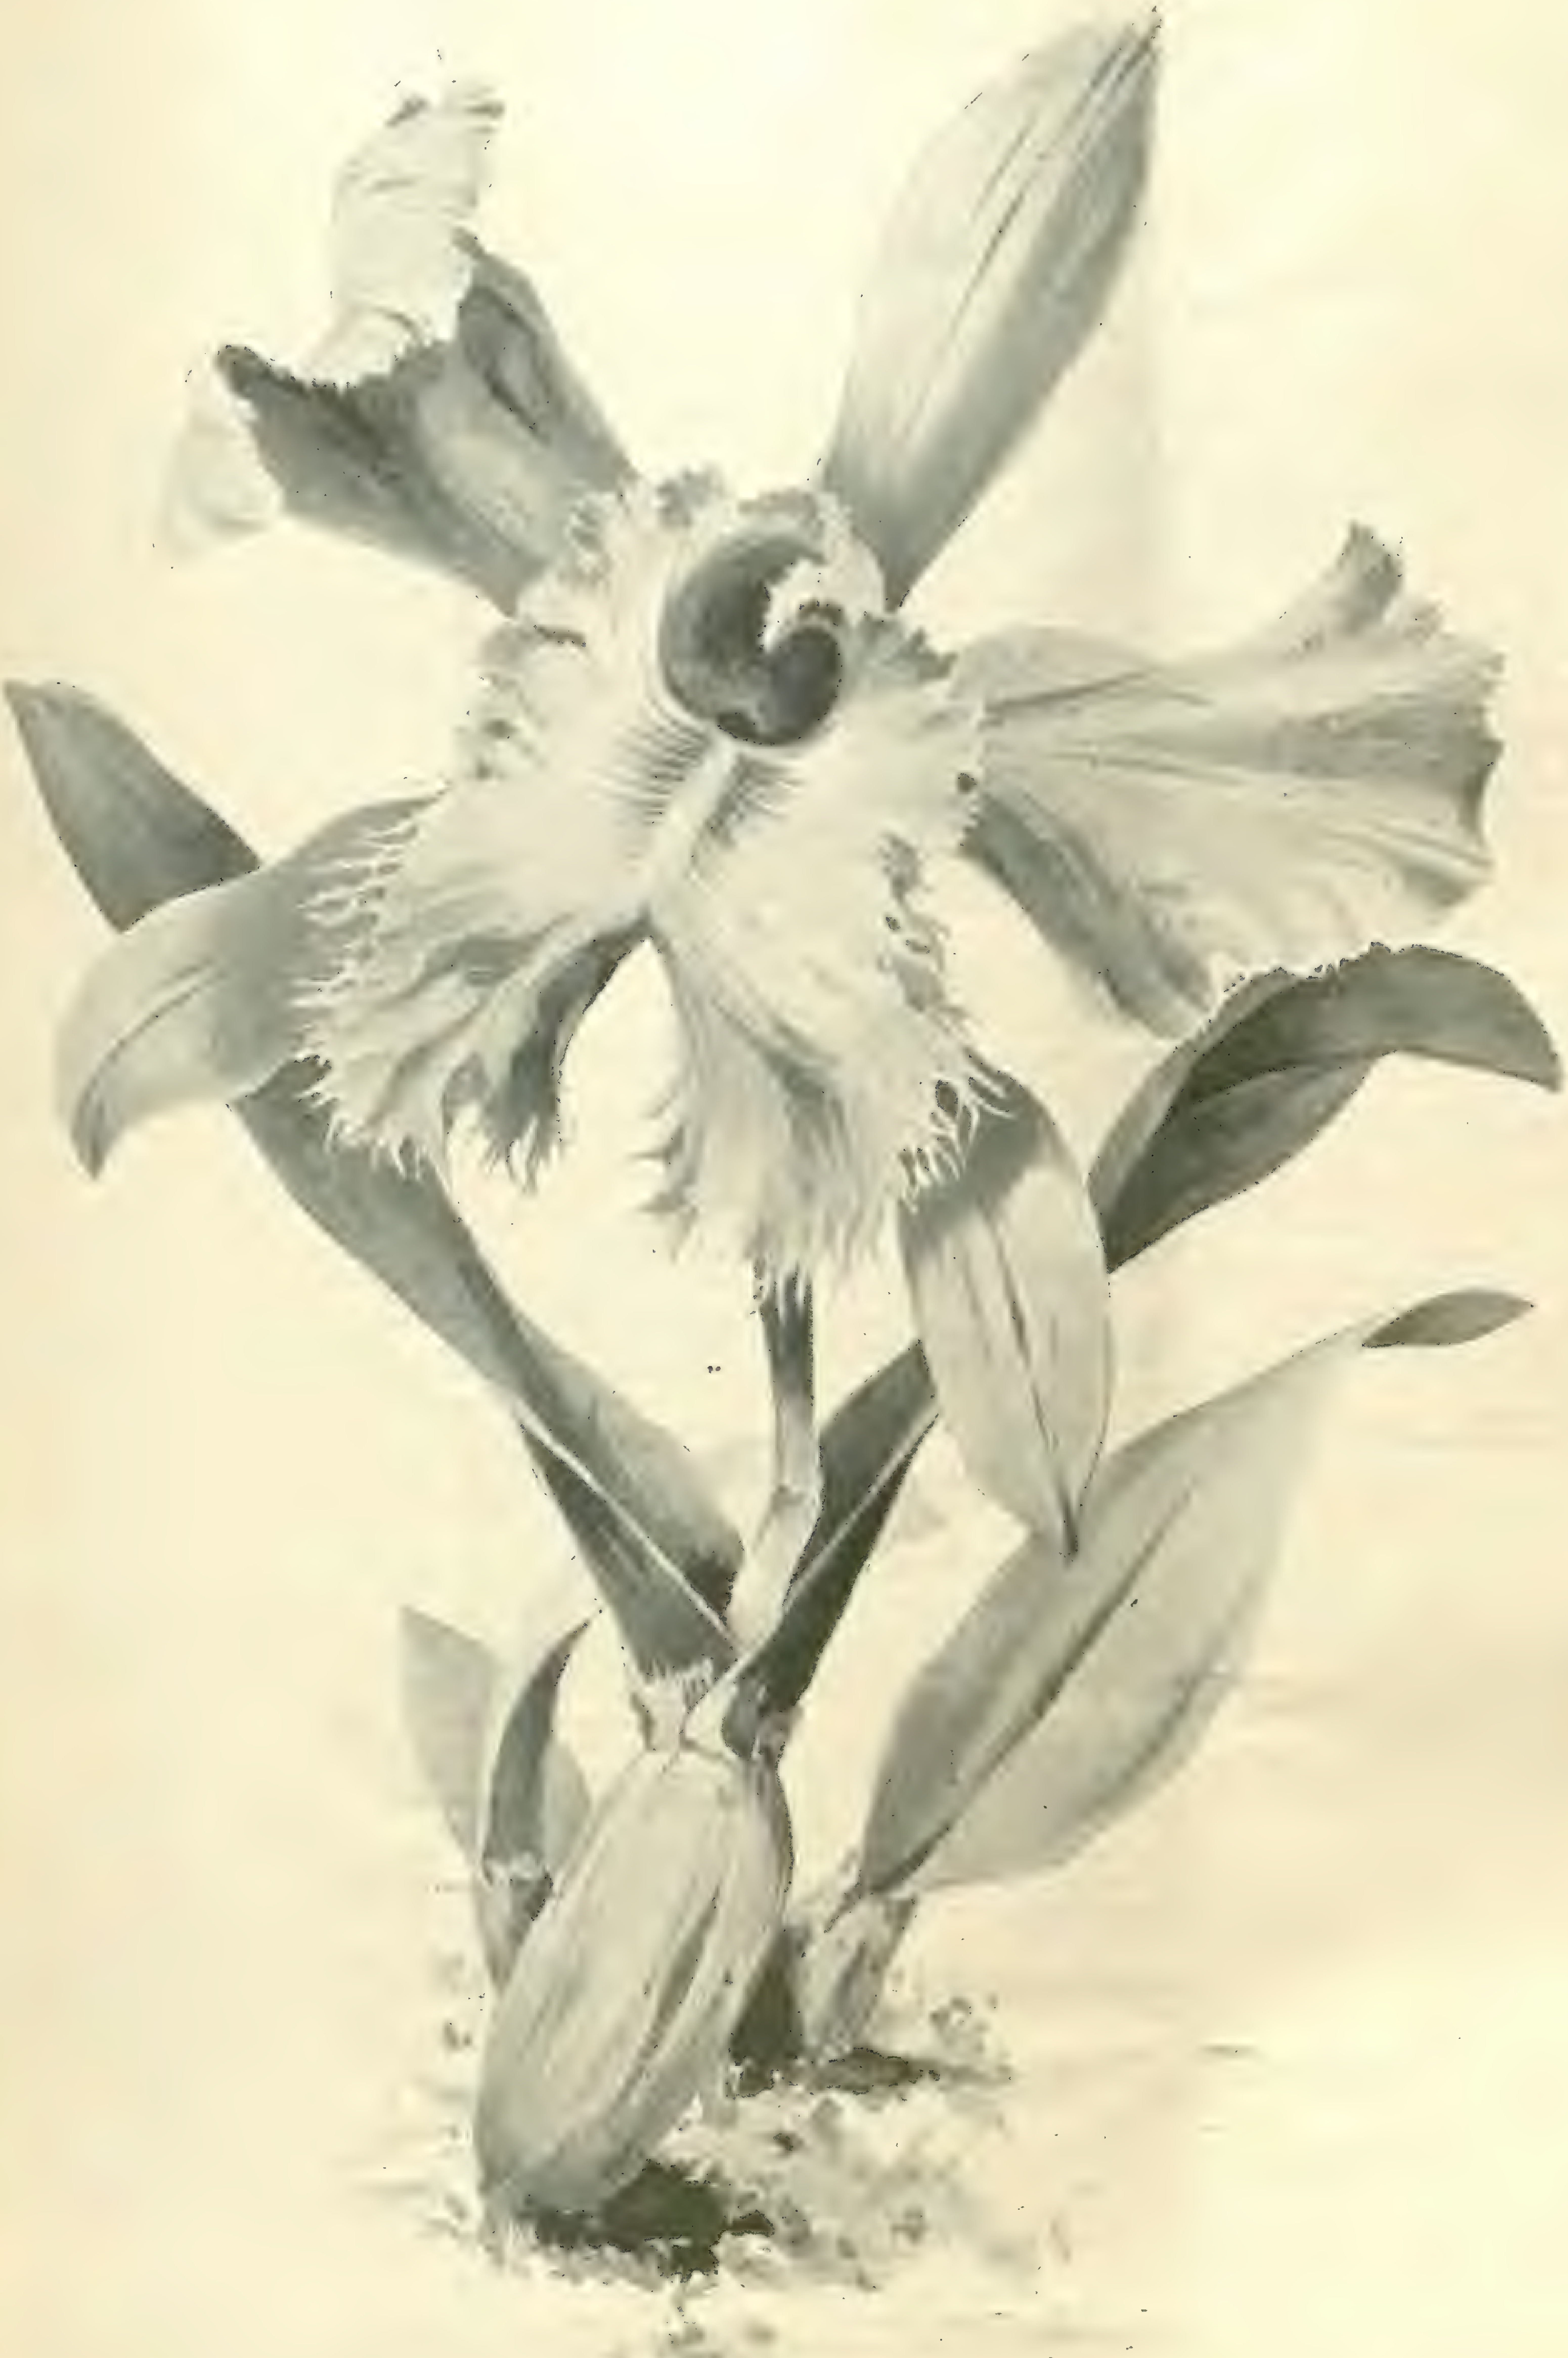
CUCUMBERS.

THREE days in succession, after the spring quarter, we had a real taste of winter; frost, hail, snow and wind, followed by a few days of rain. Yet in spite of this the cucumbers are a success, in every way maintaining a regular supply of fruit. I stop all laterals below the first wire to two leaves, so as to encourage the stem growth, though I do fruit these. All laterals and sub-laterals through the season are stopped to one leaf, and there is a gain on the short-stopping system by not only securing a certain set of fruit but also an increase of crop with shorter lengths of wood. A correspondent has asked how soon he should be able to cut after planting time. This will entirely depend on the means at disposal. I sow seed in the first week of December in an early vinery, and planting the results from forty-eights the first week of February, I cut fruit by the dozen on March 19, and this, remember, without any special hard forcing, though with bottom heat. I had no bottom heat to raise the seedlings, however, so they were longer making plants; yet no doubt when they were planted the change quickly told on them for the better. As they take, under this treatment, a lot of water to keep them healthy, though I have not syringed, it follows that repeated top-dressings are required. This is given weekly in the shape of dressings of soot and soil, silicate and soil, and a little cow manure and soil; the fourth week simply a slight dressing of loam is given, and the fifth week liquid farmyard manure. Do not give any one stimulant in strong doses. The whole surface of the bed is a mass of rootlets which are very precious, and to give an idea of the amount of dressing, in no one crop is the soil raised more than two or three inches. Though shading does not find favour here, yet in the bright weather on the 22nd ult., we had to use Summer Cloud on the west side of one house, as the sun, just shining through in the afternoon, caught the leaves a little.

Cucumber growing is a work of labour if done well, and if the crop will not pay for the labour cucumbers are not worth producing. There is, however, a bright side. The present average per week for young plants is two cucumbers each for cutting, and this will increase directly to three per plant. The aim is to secure straight fruits, and so we have a supply of hanging stones for putting on any inclined to curl, though frequently, before this, we loop the cucumber up, then weight it for the night. Not only does best fruit sell readily, but they are most easily packed. Thinning the young embryo fruits before flowering can be resorted to if the crop is likely to be too heavy for young plants, but a regular stopping and tying must be adopted, for if growth is wild strength is lost. The greatest of all evils that can befall a grower is an attack of eelworms. There is no remedy for this beyond an absolute clear out of soil, washing and starting again with soil from a fresh quarter.

Avoid sudden changes of temperature, and ventilate on the lee side with the sun. The water should always be at the same heat as the house. We have two two-inch pipes in the tanks and they serve us well. I cut on an average a dozen fruits from below the first wire, and this without injuring the plant. Less than a foot deep of soil serves my cucumber crop.

Bottesford Vineries, Notts. STEPHEN CASTLE, F.R.H.S.



LÆLIO CATTLEYA THORNTONI.—(See New Plants, &c., page 298.)

NEW PLANTS, FLOWERS, FRUIT AND VEGETABLES.

LÆLIO-CATTLEYA THORNTONI.

IN this orchid we have one of the grandest of hybrids, and one in which Lælia Digbyana has been used as a parent with Cattleya Gaskelliana. The flowers are on a plan with other L. Digbyana crosses with cattleyas, but here the lip is very long and less circular than in older hybrids. The somewhat narrow sepals are of a soft purplish rose shade, while the broad petals are of a slightly richer hue, but still soft and delicate; the margins of these segments reflex considerably. The huge lip has a big drooping apex, and over this spreads a yellow tint that commences in the yellow throat, and mingles with the rosy ground colour until the latter asserts itself along the frilled and fringed margin. In the centre of the rather square-ended apex of the front lobe, there is a large V-shaped notch that is very distinct. The flower measures nearly six inches across the petals, and is altogether a wonderful production, as will be seen from our illustration page 297. F.C.C., R.H.S., April 26. Messrs. J. Veitch and Sons, Chelsea.

MORMODES ÆNANTHEMUM.

A very interesting species, with flowers about three inches across and of a rich ruby-claret colour. The sepals and petals are all about half an inch across at their widest, the former pointing forward and two of the latter pointing backwards. The lip is very curious, the sides folding right back and forming a stiff tube. The column is twisted curiously. B.C., R.H.S., April 26. Mr. W. H. White, orchid grower to Sir Trevor Lawrence, Burford Lodge, Dorking.

CATTLEYA MENDELI VAR. BEATRICE ASHWORTH.

A beautiful form, with almost pure white sepals and petals, and a lip that is of the purest white save for the faint lemon-yellow throat. A lovely and chaste orchid. A.M., R.H.S., April 26. Mr. Holbrook, gardener to Elijah Ashworth, Esq., Harefield Hall, Wilmslow.

CATTLEYA SCHRÖDERÆ AMABILIS.

Both in size and colour this is a grand and beautiful variety, its white sepals and blush-tinted broad petals forming a fine setting for a splendid lip, yellow and rosy blush. The lip has a very broad apex, and the yellow throat extends by radiations into the front rosy area; the margin is prettily curled back and exquisitely fringed. Growth and bulbs are strong, and the flowers of great size and substance. A.M., R.H.S., April 26. Messrs. J. Veitch and Sons, Chelsea.

DAFFODILS.

Diadem has a creamy-white perianth and an immensely broad shallow cup of orange, edged with scarlet. A.M., R.H.S., April 26.

White Wing has a full pure white perianth of great substance, with narrow but very bright golden cup. A.M., R.H.S., April 26.

White Lady has very large and broad creamy segments, and a medium, soft lemon-yellow crown. A.M., R.H.S., April 26.

Will Scarlet, creamy, broad perianth segments and very broad medium cup of a rich orange-scarlet shade. F.C.C., R.H.S., April 26. All the foregoing were shown by the Rev. G. E. Engleheart.

Ivanhoe is a pretty and neat flower of the medium-crowned section; it has broad perianth segments of a creamy-white shade, and a cup that is rich orange tinted with scarlet. A.M., R.H.S., April 26. Messrs. J. Veitch and Sons, Chelsea.

PRIMROSE EVELYN ARKWRIGHT.

A giant primrose previously referred to in these columns; it is a gigantic counterpart of the common primrose and has strong foliage, has flowers as large as a five-shilling piece. A plant was found wild in Dinmore Wood, Hereford, in 1887, and the stock, now the fourth generation. has kept true from seed. A.M., R.H.S. Mr. J. H. Arkwright, Hampton Court, Leominster.

DEUTZIA PARVIFLORA.

A handsome deutzia with corymbs of white flowers, the individuals measuring nearly half an inch across; the stiff green foliage has serrated margins. The whole plant is compact, freely branched, and as freely flowered. for each branchlet ends in a cluster of flowers. A.M., R.H.S., April 26. Messrs. J. Veitch and Sons, Chelsea.

ODONTOGLOSSUM PESCATOREI DUCHESS OF WESTMINSTER.

This is a charming form of a handsome species; the flowers are of good size and shape, indeed, in these respects they would be difficult to beat. On the pure white ground are numerous medium-sized spots of rich rosy purple scattered over the whole surface. It is a most distinct form. A.M., R.H.S., April 26. Mr. N. F. Barnes, gardener to the Duke of Westminster, Eaton Hall.

MELON LORD E. CAVENDISH.

An exceptionally good early melon, and one that attains a large size even thus early. It has greenish white flesh that is of excellent flavour and great depth. A.M., R.H.S., April 26. Mr. O. Thomas, gardener to her Majesty the Queen, Frogmore, Windsor.

READ'S SPROUTING KALE.

This is a useful late kale that partakes considerably of the character of sprouting broccoli. It sprouts freely, and provides at the present time a large supply of useful and succulent leafage of a deep green colour. A.M., R.H.S., April 26. Mr. J. Read, Bretby Park Gardens, Burton-on-Trent.

AURICULAS.

Olympus, a grey-edged variety of good size; edge true; paste good; body colour slight and dark. F.C.C., N.A. and P.S., April 26. Mr. J. Douglas.

Mrs. Dumfield, a handsome violet self, with large flowers and smooth, good paste. F.C.C., N.A. and P.S., April 26. Mr. C. Phillips.

Hiawatha, an alpine variety, with dark reddish ground shading to salmon; pips large and even. F.C.C., N.A. and P.S., April 26. Mr. C. Phillips.

CAMPTOSEMA PINNATUM.

A curious Brazilian shrub with large pinnate foliage, the leaves carrying three pairs of leaflets and a terminal, each six or more inches long, and drooping. The flowers are two inches long, cylindrical; calyx greenish, corolla red or rosy purple; all the corolla segments are narrow, and have incurving lateral margins. It is a leguminous plant from Minas Geraes; seeds were sent to Kew by Dr. Glaziou, Director of the Rio Janeiro Botanic Gardens, in 1888, and a resulting plant flowered in the Palm House at Kew in July, 1897. *Bot. Mag.*, t. 7,582.

DASYSTACHYS DRIMIOPSIS.

A liliaceous plant from south-east tropical Africa; it has long green leaves and spikes of tiny white flowers. The species is of botanical rather than horticultural interest, and was first collected by Sir John Kirk in the Zambesi valley. A living plant was brought to Kew in 1892 by the late Mr. J. Buchanan, C.M.G., and this flowered at the Royal Gardens in October, 1896, after cultivation in a greenhouse. *Bot. Mag.*, t. 7,580.

ANEMONE VERNALIS.

A perennial, villous anemone, with large flowers that are white inside but violet purple on the outer surface, save for a white margin to each segment. So well known is this plant, and so closely allied to our native A. Pulsatilla, that not a few people have regarded it as a British plant, which it is not. Its distribution is from Norway to Central France, and from Saxony to the Italian Alps. *Bot. Mag.*, t. 7,581.

RICHARDIA ELLIOTTIANA.

This magnificent golden-spathed richardia is now so well known that a detailed description of it is unnecessary. It has big golden-yellow spathes of large size and large green foliage spotted with transparent white blotches. The history of the plant has already been detailed in these columns, and we refer to the species to draw attention to the double-page illustration given in the *Bot. Mag.*, t. 7,577.

DAPHNE BLAGAYANA.

A sweetly-scented daphne with terminal heads of white, green-tinted flowers. It is a native of Styria and Carniola, and was introduced to cultivation about twenty years ago by Messrs. J. Veitch and Sons. Being a very dwarf species, it is frequently used in rockeries, and succeeds here if placed amid calcareous rock; it flowers in March, and both for its fragrance and beauty is highly esteemed. *Bot. Mag.*, t. 7,579.

FRUIT PROSPECTS IN SCOTLAND.

THE promise of a full crop of most kinds of hardy fruit is at the present time (end of April) very satisfactory, apricots, peaches, and nectarines excepted. These opened bloom much earlier than usual, and consequently had to encounter the severe frosts and cutting winds that were so prevalent during the month of March, from which ordinary coverings, by way of coping boards and several folds of netting, were but an ineffectual protection. The weather, though severe, was generally dry, and the bloom being plentiful, large, and well formed, hopes were entertained that sufficient for a crop would escape, and at first these hopes appeared to be realised, but as the fruit commenced to form much of it fell from the trees, so that only a moderate crop can now be expected. The cold wave mentioned, though disastrous to early-flowering trees, had the desired effect of retarding the opening of plums, pears, and cherries, which were a few weeks ago in a very forward state. These during the past fortnight have had a very favourable period to unfold and display the abundance and richness of their inflorescence. Of these plums growing against walls took the lead, and it is very seldom that a finer and more profuse display by all varieties has been witnessed; standard and bush trees, and damsons, though later, being equally satisfactory, and appear to have set plenty of fruit.

Pears are at the present time in full bloom, which is abundant, and so well distributed that very old and widely-extended trees are gay from the main stem to the tips of the branches. The foliage this season is unfolding only slightly after the bloom, which enhances the appearance of the trees, but it doing so is not regarded with pleasure by many observant cultivators, who hold to the belief that when bloom and foliage advance together that the fruit does not set so well. Some varieties are more prone to this than others; one—Williams' Bon Chretien—I have never known to open a leaf until the flowers were passed, and this season it is no exception to the rule, either where growing upon the quince or pear stocks, or where grafted upon other varieties which show this precocity.

Cherries, both dessert varieties and Morellos, are full of bloom; the former, where growing against walls, are set, and the fruit swelling off very well. Figs are getting prominent, and indicate a heavy crop, providing no severe check from cold occurs to cause the fruit to drop. Apples will have an abundance of bloom, but as yet only the very earliest varieties are showing colour; but on walls some old trees of Ribston and Cox's Orange Pippins have their flowers fully expanded, and these, to my mind, rival the finest flowering [illegible] that could be selected to take their places, and which on losing its bloom would be valueless for the remainder of the season. Gooseberries have set a very heavy crop, and raspberries and currants of sorts promise well in bloom. Early strawberries upon warm borders are opening bloom, which is large and plentiful. For several years the annual system of cultivation for obtaining early fruit has been adopted here, and the results are more satisfactory than by following the older method of allowing the plants to occupy the same position for two or more years, as the fruits having less foliage above them obtain the full influence of the sun, and ripen earlier. Slugs and insects are not so troublesome when the change is made to fresh ground every year, and labour is saved by planting well-rooted runners in July or August, and clearing off the old plants [illegible]. Maincrop strawberries are very promising, and numerous trusses of bloom are already in evidence among the fast-developing foliage.

The season, which in this part promised to be one of the earliest [illegible], has not fulfilled the anticipations formed at the end of January, as at present [illegible] few flowers can be said to be any forwarder than they usually are at this date.

JAMES DAY.

Galloway House Gardens, Wigtownshire.

The New Cinerarias.—Very interesting it was to stand near the [illegible] the new hybrid cinerarias recently staged at the Drill Hall by Messrs. Sutton and Sons and Messrs Veitch and Sons. How very diversely were the plants regarded. The florists looked askance, regarding them as just what [illegible] in cineraria form half-a-century since. Others, taking a diverse aspect, [illegible] they were a charming break-away from the huge flowers and compact [illegible] the florist's cineraria of to-day. It is commentable to learn that whilst the [illegible] Committee would not look at them, much less make an award, the general [illegible] are calling for seed loudly, and the demand is growing rapidly. The [illegible] feature of the new strain is the adaptability for furnishing flowers for cutting, [illegible] long stems. For that purpose the flowers now are large enough, but the colours greatly need brightening and improving. That seems to be the object the raiser should now aim for.—A. D.

CRICKETING is one of the healthiest exercises amongst our British sports, but [illegible] be excelled in by men possessed of a sound constitution. Even then care must be taken to [illegible] the strength and elasticity of the frame by a judicious course of training. The best [illegible] direction are Holloway's Pills and Ointment. The former invigorate the system and [illegible] blood, while the latter strengthens the muscle, takes the stiffness from the [illegible] cure for sprains, bruises, and contusions. Thousands of testimonials have [illegible] parts of the world, giving evidence that these wonderful remedies will cure [illegible] which afflicts humanity. Full instructions are given to each purchaser.—[Advt.]

WORK FOR THE WEEK.

WARM ORCHIDS.

PHALÆNOPSIS, after having their annual overhauling in the way of adding new material and giving a thorough cleansing, providing they have had the advised treatment, will now be gaining vigour; always, after the flowering season, the foliage flags more or less, as in some other orchids. Syringe between the cylinders early in the forenoon, and give a slight fine spray over the leaves, but care must be taken not to lodge water in the heart, or rot may set in, and ultimately kill the whole plant. If any are grown in baskets they must be suspended over the pathways, so that they are under control of the syringe; all should again be damped round early in the afternoon. The shading must be put down early in the morning, but top air must be avoided at present, the bottom ventilators being used only, though on both sides when the weather is favourable. Liquid cow manure may be used under the stages and about the pathways about twice a week, or cow manure on the one occasion and soot water the other. Carefully sponge phalænopsis leaves with soft-soap water in a weak state, as they enjoy cleanliness. The young fleshy roots are now working freely, and will require to be watched, or slugs, beetles, woodlice, &c., will spoil them; a few young lettuce leaves will entice and trap slugs, and may be examined by lamp light in the evening.

Cypripedium bellatulum will now be coming into flower, and short crutched sticks should be used for the flowers if effect is considered. Hybrids from it and Cypripedium niveum should be served likewise. Cypripediums may have a slight syringe overhead early in the forenoon as well as a good damping between the pots, under the stages, and pathways. In the case of selenipediums great care must be taken as to watering, as they are queer subjects, and over-watering will soon produce rot at the base of the growth; a slight syringe, however, is beneficial. Selenipedium macrochilum and its variety giganteum will be flowering, and it is a good plan to raise them on pots to afford the petals plenty of room for development; neat strong sticks to support the flowers will be necessary, but here, as with other selenipediums, such as S. caudatum, S. nitidissimum, S. grande, &c., great care must be taken to keep water from the flowers. More shading will be necessary, and if the cotton blinds are of a thin texture the glass will need to be slightly limewashed. These selenipediums and other cypripedes will require more moisture in the air now, and liquid cow manure will prove very beneficial if thrown under the stages and on pathways; the best time to give this is in the evening, thus allowing the plants to have full benefit of the stimulant while all is quiet and close.

Chysis bractescens will have finished flowering, and ought to be removed to the dendrobium house; amateurs will find this thrive better than grown in the Mexican house, and plenty of water afforded during its growing season. I would strongly advise all that have recently purchased imported cattleyas to carefully examine them and see that they are perfectly free from cattleya fly before placing them along with the rest of the collection, for it is without doubt a terrible pest if not kept down. It is sad to find it in a good hybrid, attacked perhaps in different places at various periods; first of all in the lead, which has to be cut off, then the back eyes begin to go, and this means the ruin of perhaps an expensive plant. The cattleyas may be sprayed morning and afternoon on bright days, taking care not to wet the flowers; more damping will be necessary, and shading given when necessary, and air put on to keep the atmosphere balanced according to outside conditions.—T. STAFFORD, *Tyntesfield Gardens.*

CONSERVATORY AND GREENHOUSE.

THE various plants that will be required to furnish the stages during the summer months would be the better for having the flower buds pinched out until within a week or so of the time they are required to give a display. Standard fuchsias and heliotrope, when nicely grown, form pleasing objects dotted between dwarfer growing plants. To obtain evenly-balanced heads frequent stopping of the leading and strongest shoots is necessary. For covering back walls, or trained up the front rafters, and so on to the roof, these plants are also useful. Creepers of different kinds should be attended to at least once a fortnight, to thin out crowded shoots and train others evenly. Bougainvillea glabra loses half its charm when the shoots are not thinly disposed. The plants should be looked over before growth gets too far advanced, and the main branches disbudded, which will save the removal of a quantity of growth later on. Lapagerias will now require copious supplies of water, or they will fail to give that wealth of bloom afforded by plants well nourished. When the two varieties, rosea and alba, can be grown side by side, so that the sprays of bloom are intermixed; they make a very pleasing feature as a covering for the roof. To propagate these plants a few of last year's shoots should be layered in sandy soil and kept continually moist.

Cannas in variety are most useful and ornamental as pot plants, therefore a good number should be potted on, giving them rich soil and a close humid atmosphere. Lilies of different kinds should receive a top-dressing of rich compost to induce new roots to form at the base of the stem. L. Harrisi will now be coming on in quick succession, and some of the plants should be placed in a cool shady position to retard them as much as possible. Celosias should receive larger pots as required as when once allowed to become pot-bound or dry at the roots they seldom succeed afterwards. Heat, moisture, and rich soil suits these. Tuberous-rooted begonias may be divided if it is necessary to increase the stock of certain varieties. Large bulbs may be divided into three or more parts after a few shoots have formed. The parts should be placed in shallow boxes filled with sandy soil and kept moderately moist until roots form and leaf growth increases, when they may be potted off singly or placed in hanging baskets.

The early batch of winter-flowering carnations should be stopped and potted on as required, and for a time a growing atmosphere should be maintained in the house they are growing in. We find some of the border varieties very valuable for giving a quantity at Easter, notably Duchess of Fife, and those who have not succeeded with the tree section should give this variety a trial in pots. The perfume and colour of the flowers is most pleasing. Early layers should be obtained so that the pots are well filled with roots by August; then the most of them will have practically formed flower stems, and only require the warmth of any ordinary greenhouse in February, to have them in full bloom by the season named. A late batch of both primulas and cinerarias may be raised from seed sown now. Less heat is necessary now the season is so far advanced, ours being raised under handlights in a cool north house. Former batches will have been potted off singly, and for a time they may be arranged somewhat thickly on a cool bed of fine ashes, where they are kept more uniformly moist. All plants, directly the flowers fade, should be removed from the conservatory, as more than probable many of them will have been attacked with green fly, owing to the syringe not having been used while they were in bloom. The time taken very often in staking and tying different plants is a great mistake, as the fewer sticks used the better, and the plants present a more pleasing appearance. One neat stick in the centre is often sufficient to meet all the requirements in the way of support.—R. PARKER, *Goodwood.*

THE FLOWER GARDEN.

HERBACEOUS borders will require considerable attention at this season. In dry weather a hoeing over occasionally should be given to keep down weeds. For adding to the display in these borders and to fill up any spaces a few select annuals may be sown, as the best effects are obtained by the employment of a few varieties sown in moderate quantities, rather than an indiscriminate mixture of many kinds. For this purpose Linum grandiflorum coccineum, godetias, Tom Thumb nasturtiums, Collinsia bicolor, Clarkia marginata fl. pl., and others are adopted as dwarf or low-growing varieties; while for taller kinds, lavateras, annual chrysanthemums, coreopsis, blue cornflowers, sweet sultan in variety, and others may be used. Besides these, annuals sown in frames for transplanting, such as stocks, asters, salpiglossis, marigolds, Nemesia strumosa, annual sunflowers, sweet scabious, &c., are also often useful for this purpose. Towards the back of herbaceous borders, sweet peas may be sown in rings, if space permit, a couple of feet in diameter, and a few sticks be placed in the centre for them to eventually cover, or in small patches if more desirable. Seeds of some of these annuals are very small, and should be scattered on the surface and slightly raked in, while for those of larger size drills or cavities, sufficiently deep to allow of the seeds being well covered, should be drawn out. On these borders some subjects will also need attention in the matter of staking and tying, and more especially does this refer to the herbaceous pæony. These showy plants are fast developing their flower heads, and before further advanced the clumps should receive some kind of support, otherwise, with heavy rain or wind, the growths fall over and soon become spoilt in shape, and are of little use after having once fallen either for cutting or garden decoration. For the sturdy growers of medium height similar to the old P. officinalis, it is my practice to pass a piece of tarred string around each clump just under the foliage when the flowers are in the bud stage, drawing the heads together moderately tight but using no stakes. Treated thus they keep erect and spread open just enough by the time they are in bloom to look natural and show the flowers off to advantage. For taller growers one stout stake is used, placing it at the back of the plants out of sight. The tarred string is passed round the clump beneath the foliage and secured to the stake behind. These subjects are much benefited by the application of good soakings of liquid manure of moderate strength, especially after such a dry spring as the present one, particularly to large and old-established clumps.

The early spring-blooming anemones are useful subjects for cutting or filling small beds. The strain known as St. Brigid's produces a great variety of colours ranging from scarlet to pure white, with both double and single flowers that continue to expand over a considerable period of time. Seeds, if sown forthwith, will produce flowering plants for the coming winter and spring. The soil should be deeply dug and manured, small permanent beds being desirable. Anemone seeds may the more readily be sown if rubbed out with a little silver sand. Primroses, polyanthuses, and Alpine auriculas may also be sown now for the production of flowering plants for next spring. A frame on a spent hotbed, and sowing in light sandy soil, is one of the best means of raising these seedlings, pricking them out on a somewhat shaded border as soon as they are large enough to handle. Young plants of dahlias recently struck in thumb pots should be given a shift into a larger size, rather than allow them to become unduly pot-bound before planting out time, which will scarcely arrive for another fortnight at least. They should now be standing in cold frames and have the lights removed in warm weather. Where old stock roots are merely split up into convenient sized pieces before planting, and little growth has started, they may be planted out about the middle of the month. The flowers from these will be scarcely equal to those from young newly propagated plants, but at the same time they answer well for garden decoration, and produce a quantity of flowers. All dahlias are best mulched with short manure after planting. For use as cut flowers, no section is equal to the true cactus type, these having the advantage over the single varieties of lasting longer in good condition.—C. HERRIN, *Dropmore Gardens.*

KITCHEN GARDEN.

EARLY potatos planted in March have pushed through the soil in some localities, and whenever they appear material should be at hand so as to afford protection against frost, for if once the haulm is cut back the crop is seldom worth lifting. Early planted potatos require a lot of looking after unless a framework be made in the first instance, so that a covering of canvas or straw mats can be put over during inclement weather. Those planted at the foot of a south wall will need watering unless rain has fallen since writing, as the soil has become somewhat dry, and in districts like this, where but little rain has fallen during the present year, the tubers will be small unless assisted. The planting of late varieties should at once be brought to a close, as all danger of frost will be past before the growth appears through the soil.

In the southern counties, and sheltered places where protection can be afforded, a sowing of both scarlet runners and dwarf French beans may be made the first week in May. The former will not have grown too much to require staking before all danger of frost is over, and the latter may easily be protected with mats placed over hoops. These early sowings are always serviceable, as they come into bearing at a time when asparagus is failing. Where room can be found in a cold frame seed of some of the early dwarf kinds may be sown in pots to be brought forward with a view to planting out when danger of frost is past, about half a dozen seeds being placed in a six-inch pot. These can be thinned out before the plants become crowded to two or three.

In most places the main sowing of broccoli may now be made, taking care not to sow too thickly, as the plants are apt to become crowded before they are large enough to transplant. The early sowings should be kept free from weeds, and be assisted by the application of weak liquid manure. Should the turnip-flea beetle make its appearance dust the plants with lime after watering. As the plants become large enough for transplanting see that they are put out. If room cannot be found for them in their permanent quarters, prick them out about six inches apart each way. As the ground becomes cleared of those ready for use it should be manured and dug ready for late peas, it will then be settled down before the time for sowing arrives. Turnips will now grow more freely than those sown earlier, it is, however, advisable to make only small sowings, as in hot weather the roots soon become tough and stringy. For the present Snowball, Stropleaf, or the Early Stone are the best. The ground must be liberally treated for this crop, and plenty of moisture should be given to keep the plants growing. In hot weather the turnip-flea is very troublesome, but this may be kept under if the plants are well supplied with nourishment.

The early peas on borders will now be showing bloom in most sheltered gardens, but unless rain is forthcoming a liberal supply of water should be given to enable the pods to swell quickly. With us the autumn-sown peas look well at the present time, and should no severe frost visit us this month they will be fairly early. With many the main crop of carrots is sown about the end of April, but it is not advisable, where the ground is in good heart, to sow too soon as fine roots may be had from sowings made towards the end of May. But to keep up a succession a sowing of Matchless, James's, or Intermediate may now be put in, deferring the main sowing for another week or so. During the dry weather keep the hoe at work amongst such crops as onions, parsnips, carrots and other small plants, for if the weeds are allowed to grow they will soon spoil the most flourishing of these. Do not neglect to make frequent small sowings of radishes, lettuce, mustard and cress, and other salads. A cool shady place should be found for those used in a small state, as the foliage will be more tender than when grown in the sun.—H. C. PRINSEP, *Buxted Park Gardens.*

HARDY FRUITS.

IN the southern parts of the country I fear the peach and nectarine crop has suffered greatly from the severe weather experienced at the end of March. Many of our trees were in bloom, and some have not a single fruit, no matter what protection they had. Our friends in the north will have escaped, and I am pleased to remark some of the late flowering kinds have set well. This shows the advantage of having different positions and varieties, as if one lot suffers the others may be saved. I once had some excellent crops of peaches from an east wall when those on the south were quite barren. Apricots appear to have suffered less than peaches, doubtless owing to the fruits being set before the severe weather set in. The recent rains have been specially welcome, for fruit trees under wide copings are very dry at the roots. Thinning of apricots will need attention, as it can now be seen what fruits are taking the lead, and it will be safe to remove many of those thickly placed and to reduce the wood growths such as foreright shoots and those not needed for extension. Cherries are blooming very freely, and in our case small birds have been more active than usual in the destruction of buds, and netting became a necessity, Black fly is one of the worst pests we have to deal with in our light soil, and the fruit-grower's task is not an easy one; but wherever it appears active measures must be taken, as it soon destroys much foliage. Dusting with tobacco powder is effectual in mild cases; in others it may be advisable to syringe with tobacco-water or quassia. Newly-planted trees should now be carefully trained, it being important to have the principal leaders in position, and in the case of stone fruits much may be done by pinching shoots not required for extension in preference to using the knife the first season. With drying winds, mulching must not be overlooked, and a thorough watering afterwards will keep the roots active. Now is a good time to reduce the shoots at the stools of raspberries—I mean summer-fruiters; if all are left, they are so numerous they crowd those needed for next year's canes. I prefer to pull them out with the hand, as if merely hoed they soon reappear. Pear and apple trees are this season showing a wealth of bloom. I fear some of the earliest pear blossoms have been injured, but it is too early to speak definitely. Plums are equally good, and other fruits appear to be making up for last year's deficiency.

Strawberries will now need early attention, as on south borders the flower trusses will be showing freely, and I would advise mulching before the flowers expand. There are several ways as regards mulching, and I have tried most of them, but have been obliged to revert back to the old but effectual one of using litter from the stables. I am aware litter in a fresh state with ripe strawberries is objectionable, but placed in position now, that is, a month or six weeks before the fruits ripen, it becomes quite clean by exposure to the rains, and sweet. Grass from lawns is at times advised. I do not know of anything worse, as in a wet season it is infested with slugs and worms, and adheres to the fruit. Clean long straw is not the best protection, as it lays so close to the soil it soon decays, whereas litter is more elastic, and dries sooner. I have seen many crops injured by leaving the mulching till too late, as one heavy storm will cover the fruit with grit, and another point worth noticing is that strawy litter placed in position now may be made good use of should severe frosts follow, as it is a simple matter to shake the litter lightly between the blooms. Last May was one of the worst seasons on record, as frosts destroyed so many of the first blossom, causing severe losses. It is well to be prepared for emergencies. Those who have dry bracken may with advantage use this for protecting, but it is not plentiful near towns, and is not of much value, unless cut in the early autumn and dried. It will well repay the cultivator who has a few rows of early strawberries on a south border to protect with hand-glasses or spare sash-lights, as by so doing fruits may be secured ten days or a fortnight in advance of those not protected, and there is always a brisk demand for the fruits in the open at the season named, as forced strawberries are not plentiful, the season being over. There should be no delay in hoeing through strawberry quarters before giving a mulch; indeed, I prefer to do the work several times, as there is less trouble with weeds during the fruiting season. Spring-planted runners will be benefited by removal of flower spikes if at all weak, as these will not be strong enough to produce a good crop, but they will make up for the extra time given next year by the size and quantity of the crop. Alpine strawberries raised from seed in boxes under glass, if pricked off into frames or boxes some time ago, will soon be in condition to plant out in well-prepared land. Later seedlings should be pricked out and given glass protection for a little longer to give them strength. These will be useful for the supply of late autumn fruits. Last year's plants will need liberal supplies of food, and the surplus growths removed, to give the young fruiting growths more space.—G. WYTHES, *Syon Gardens.*

Onions.—In Mr. Beckett's recent excellent article on "Onions" in the GARDENERS' MAGAZINE, he mentions that the autumn-sown never keep well, and further on he notices the Rocca varieties with some measure of favour. To my mind, the connection is the cause, as, if I wanted onions to keep and be of service after grown, I would never grow Roccas; their texture is of the coarsest, and after you have carefully grown and harvested the crop you may begin throwing them away. There are several very good kinds for autumn sowing; one that I am very partial to, and Mr. Beckett does not name, is Trebons. Whatever I sow in autumn I always include this, and for a good many years now I have never been without onions all the year round. As to spring-sown, many growers, in my opinion, thin the crop too much. If onions are wanted to keep, they must have small necks and be well ripened; this is best effected by growing them thickly in rows, even pushing each other before full grown; there are always enough large ones, and for the general supply of the household, those of a moderate size are most acceptable. For keeping, flavour, and texture of flesh I have not found any to beat the Improved Reading. The bulk of my last year's crop of autumn-sown onions are now gone, but I take the liberty to enclose a sample of Trebons grown from seed sown in August, 1896, to back up what I have written. I am aware the article in question deals primarily with onions for exhibition, and I may be reckoned out of court; at the same time, it is well to know what is best for general utility.—J. HARDING, *[illegible], Sussex.*

[The three specimens sent were of medium size, clean, shapely, firm, and solid, thoroughly bearing out Mr. Harding's statement as to their keeping quality.—ED. G. M.]

THE VICTORIA AND PARADISE NURSERIES.

THESE old-established nurseries, situated at the foot of Highgate Hill, always repay a visit, as besides the usual large stock of ordinary nursery stuff there are several classes of plants that are made a speciality of, and others not commonly seen. Messrs. B. S. Williams and Son have recently disposed of their frontage upon the Junction Road, and the land formerly occupied by a camellia and azalea house; with this exception the nursery remains as of yore. In consequence of increasing business, however, the firm is creating a branch establishment on the breezy slopes of Finchley, where they have taken a nice little estate of some four[illegible] acres. At this branch they will have more room for cultivating large batches of flowering plants and such subjects as are technically known as "furnishing plants," wherewith to meet the increasing demand that comes through their florist's shop on Piccadilly. Here also hardy plants can be readily grown, and such orchids and stove plants that do better under a stronger light than that of Upper Holloway will find a place.

Palms are extensively cultivated at Victoria and Paradise Nurseries, and one can here be suited with either a tiny seedling or a fine towering specimen fifteen to twenty feet high. The large house near the office contains many very handsome examples of Kentia Forsteriana and K. Belmoreana, Areca Baueri, Latania borbonica, Rhapis humilis, and a number of splendidly furnished and large examples of the ever-popular and elegant Cocos Wedelliana. Of the latter and the two first-mentioned palms there are large stocks in all stages of development, while of others, such as Geonoma gracilis, Cocos plumosus, Phœnix dactylifera, and P. reclinata there are numerous neat specimens. Bamboos for indoor decoration are not by any means forgotten, as every day finds these beautiful Japanese plants becoming more and more popular; three especially useful sorts well represented here are those known commercially as B. aurea, B. gracilis, and B. Maximowiczi variegata. Stove plants occupy a good number of houses; Anthuriums, both Andreanum and Schezerianum varieties and hybrids, are freely grown, and show that the Holloway firm is perfectly well acquainted with the variations of the wind of fashion. Of aralias such as A. gracillima, A. Veitchi, A. elegantissima, and A. Chabrieri, the Messrs. Williams always have batches in the best of health and in all stages of development, from the newly grafted or rooted plants up to the perfect specimen. Dracænas in all leading sorts, and crotons in great variety, are now colouring freely; the anthuriums notable for their handsome foliage, such as A. Veitchi and A. Warocqueana, need special mention, as they are thrifty plants capable of making grand examples for large houses. This firm has long enjoyed a special reputation for ixoras, and does not appear likely to lose it, judging from the stocky plants of I. Duffi, I. Williamsi, I. Fraseri, I. coccinea, I. Prince of Orange, &c. It is useless to further enumerate the stove plants here to be found, but several somewhat rare subjects that attracted attention from among a host of others were [illegible] decorans, with trusses of golden flowers; Franciscias, now too seldom seen, and resplendent in shades of blue; Carludovica plicata, a palm-like plant; Cyanophyllum magnificum, Dracæna Doucetti, and the elegant D. Godseffiana, Ficus Cooperi, a handsome plant; and Artocarpus Cannoni.

Begonias, both winter-flowering and Rex forms occupy considerable space, and have to be freely propagated to meet the growing demand; Gloire de Lorraine and Gloire de Sceaux are now flowering. Among the foliage kinds Messrs. B. S. Williams and Son have some good new varieties, such as Ville de Paris, clear silver with green veins; Tananarive, creamy silver with green mottlings; T[illegible]tave, also silver and green, but very distinct in the markings; Chicago, [illegible] handsome foliage, broadly lobed margins, green centre surrounded by silver and with green spottings toward the margin; and an unnamed seedling with deep purplish centre surrounded with silver, and with a rosy-tinted margin. All the older varieties find a place. Caladiums, araucarias, amaryllis, clivias, sarracenias, nepenthes, and cannas attract attention by reason of their numbers and good appearance. The amaryllis are seeding freely, and consequently must have flowered well; the clivias are almost over, but a few remain to indicate the fine strain to be found at Holloway, a strain remarkable for large trusses, substantial flowers, and high colour. The cannas are a first-rate stock, and include the Crozy and Lemoine varieties, the grand new Italian sorts, the best English seedlings, and several fine American sorts; among the latter is a dwarf scarlet and gold form named Mrs. Fairman Rogers, and one of great value. Carnations are specially clean stocks of thrifty plants, and there is a big demand for such varieties as Souvenir de la Malmaison, Princess May, Churchwarden, Queen of Yellows, James Mushlark (maroon), Duke of Fife, Duchess of Fife, Uriah Pike, and John Peter Rugus, a fine red variety. Abutilons, humeas, genetyllis, the pretty variegated Poa argentea (fine for edging), and the variegated form of Agapanthus umbellatus were other cool house subjects deserving of special mention, not omitting big stocks of the golden-spathed richardias.

Passing to the extensive orchid department one is charmed by the multitude of spikes of Odontoglossum crispum, O. triumphans comprising many very handsome forms; O. cirrhosum, O. Ruckerianum, O. excellens, O. Wilckeanum, O. luteo-purpureum, O. Rossi, O. Andersonianum, &c., all on healthy plants and carrying fine flowers. Hanging in a warm house are goodly baskets of Pescatorea Lehmanni, P. Roezli rosea, P. Klabochorum, P. Pantini, and Bollea cœlestis. Phalænopsis Schilleriana and Vanda teres are either flowering or promising flowers on nearly every plant. Cypripediums are doing well, both species, varieties, and hybrids; a few sorts that we noted in the several houses devoted to these orchids were C. Morganiæ, C. Mastersi, C. Io superbum, C. Measuresianum, C. Fitcheanum, C. Charlesworthi, C. Leeanum, C. nitens, C. Chamberlainianum, C. œnanthum superbum, C. grande, C. Sedeni, C. Gertrude Hollington, C. Lebaudianum, and C. Ashburtoni; all other leading kinds are grown and grown well. Dendrobiums and thunias, pleiones and lycastes are well represented. Vandas are a splendid sight, for not only are the specimens clean and furnished to the pots with stout foliage, but large numbers are now in full bloom, especially V. tricolor and V. suavis forms, so that the senses of sight and smell are equally gratified; the vanda house at Holloway is a revelation to many orchid growers. Miltonias and cymbidiums are freely flowered, and the varieties are good; Cattleya Mendeli is very fine, as the firm has a selection of beautiful forms [illegible] represented by fairly large examples. Cattleya citrina and C. Lawrenceana [illegible] contrasting colours, and in an adjoining house are many fine specimens of [illegible] purpurata, now commencing to flower, and including the exquisite L. [illegible] Williamsi. A few other orchids now flowering and not previously [illegible] include the rare but handsome Oncidium loxense, the long-spiked O. [illegible]thum, Odontoglossum Harryanum, O. polyxanthum, O. sceptrum, Tr[illegible] suavis, and the pretty, late-flowering Calanthe Sanderiana.

Altogether there is much to interest and instruct a visitor at the Victoria and Paradise Nurseries, as many will discover during the present month, for May is a popular time for nursery visiting through the metropolitan district, especially about the time of the Temple Show.

HORTICULTURE IN CANADA.

IN the discussion of horticulture in Canada it is perhaps best to treat of horticulture in its widest sense, as embracing the art and science of the cultivation of trees, shrubs, and plants for both utilitarian and decorative purposes. This subject, stated Professor W. Saunders, of Ottawa, at a meeting of the Massachusetts Horticultural Society, covers so wide a field that the brief period of an hour will admit of touching on but a few of its more important features, and, with the view of presenting these in a clear and intelligent manner, he first gave a very short sketch of the country whose horticultural progress he had undertaken to outline.

Geographical Description of the Dominion.

The Dominion of Canada consists of seven provinces, four provisional territories, and a vast area to the north, much of which is yet unexplored. If the traveller through this country takes the train at its eastern boundary, at Halifax on the broad Atlantic, he may ride with one change of cars through to the shores of the Pacific, covering a distance of 3,662 miles, and all within the settled area of Canada. The three most easterly provinces form a group partly surrounded and more or less intersected by the ocean, known as the Maritime Provinces. Following these come the goodly provinces of Quebec and Ontario, the latter stretching westward along the margins of the Great Lakes—Ontario, Erie, Huron, and Superior—until its western boundary is found beyond the Lake of the Woods. Here Ontario joins the "prairie province" of Manitoba, west of which lie the four gigantic provisional territories—Assiniboia, Saskatchewan, Alberta, and Athabasca —comprising vast plains. In part of the territories a wide belt of the country, lying north of the forty-ninth parallel—which forms the boundary line between the United States and Canada—has a dry climate, caused by the hot winds which blow northward from the great American desert. But beyond the spent force of these hot currents, beginning from one hundred and twenty-five to one hundred and seventy-five miles north of the boundary, we find immense partly wooded areas, watered by streams flowing northward, with a soil wonderfully rich and fertile and with conditions favourable for mixed farming, especially for the raising of cattle and for dairying. Still further west stands British Columbia with its sea of mountains enclosing an area abounding in minerals, coal, and lumber. Its waters teem with fish, and some of the fertile valleys are being fast converted into smiling fields of grain and prolific orchards.

Let us touch briefly on the conditions found in each of the divisions of this your neighbouring country, and note the indications of horticultural progress. Prince Edward Island, the smallest of the provinces of Canada, has an area of 2,133 square miles, is one hundred and fifty miles long, and varies from nine to thirty miles in width, and has a population of one hundred and ten thousand. This island has a fertile soil; the climate is cool and bracing in summer, but rather severe in winter. Many varieties of apples, plums, and cherries succeed well there, and gooseberries, currants, and other small fruits are produced in abundance; but the winter season is too severe to admit of growing the more tender fruits successfully. The cultivation of flowers is very general, especially in the cities and towns, in which many avenues of stately trees are found, most of which are European. So also are the shrubs which decorate the grounds about rural and city homes. The number of varieties of trees grown are few, and in shrubs one notices the absence of many beautiful forms which are grown very successfully in other provinces, and which will, no doubt, when introduced, do well here. Horticulture is encouraged by the holding of exhibitions of fruits and flowers in the capital at Charlottetown and elsewhere, which are assisted by grants from the provincial treasury. There is a fine park in Charlottetown, comprising about one hundred and fifty acres, with beautiful drives through the wooded areas and along the seashore—a cool and delightful place of resort for the citizens throughout the summer months.

Across the Northumberland Straits from Charlottetown, some thirty miles distant, lies the province of Nova Scotia, with its twenty thousand five hundred and fifty square miles of area, and a population of four hundred and fifty-one thousand. The climate of the eastern part of this province is mild and well adapted for the growing of many varieties of fruit of high quality and in great perfection. The Annapolis valley, so well known as the scene of Longfellow's beautiful and tragic poem, is specially adapted by climate and situation for fruit growing, and is rapidly being converted into a vast orchard where the choicest sorts of apples, pears, plums, and cherries grow in the greatest abundance. In this valley there is a special school of horticulture, receiving a liberal provincial grant, where practical training is given to students in the propagation and growth of fruits, ornamental shrubs, trees, and flowers. To drive among the beautiful scenes in that charming valley, when the trees covered with blossoms in the spring, or when their branches are pendant with golden fruit in the autumn, is a delight not soon to be forgotten. There are many other localities in Nova Scotia where fruit culture is carried on very successfully, and the exports of fruit from this province are large and constantly increasing. The Fruit Growers' Association of Nova Scotia, which is also aided by provincial funds, is a strong and active organisation, holding meetings at intervals during the year for the discussion of subjects relating to fruit growing and other branches of horticulture, and the information brought out is published in the proceedings of the Association. During the past year the quantity of apples exported was about five hundred thousand barrels. Some of this fruit, I am told, finds its way to Boston, where the high-flavoured Gravensteins are said to be much appreciated; but much the larger portion finds a ready market in the larger cities in Great Britain. In Halifax there are several parks, including in all about two hundred and eighty acres. The Public Gardens, containing about sixteen acres, are also very attractive, and contain some excellent specimens of trees, mostly European, and many varieties of shrubs and conifers, including some choice specimens of Japanese Retinosporas, notably of *Chamæcyparis plumosa* and *C. plumosa aurea*. The Scotch heather, *Calluna vulgaris*, also luxuriates here, and some of the fine flower beds are margined with this pretty plant, which has become naturalised and is growing in large patches in the public parks. Truro and other smaller cities and towns west of Halifax are emulating the capital in the establishment of parks, adorning their streets with avenues of trees, and embellishing their homes with groups of choice shrubs and beds of flowers.

New Brunswick, Quebec, and Ontario.

In New Brunswick, with an area of twenty-eight thousand square miles and a population of three hundred and twenty-one thousand, the climate is not so favourable for general progress in horticulture as in the sister province of Nova Scotia. While orchards have been successfully established in the valley of the St. John river, the varieties of fruit grown are chiefly of the hardier sorts, and the cultivation of large fruits is not general. Small fruits, however, are grown in abundance, and the cool weather in early summer retards the ripening season and permits of the growing of large quantities of luscious strawberries, which, ripening after the main supplies in the New England States, find a ready market in Boston and other cities, with but little competition and at good prices. Recently a public park, comprising two hundred and forty acres, has been established at the City of St. John, occupying a commanding position overlooking the turbulent waters of the Bay of Fundy. Through this park roads are being laid out amidst charming and, in some places, rugged scenery. This must in time become a most attractive place of resort.

The Province of Quebec, with an area of two hundred and twenty-seven thousand square miles, and a population of about one and a-half million, is also making progress in horticulture. In the valley of the St. Lawrence there are many fine orchards, and nowhere does the celebrated Fameuse apple reach so high a degree of perfection as on the Island of Montreal, where many varieties of pears also, and plums of fine flavour, thrive well. In the eastern townships, on the south side of the River St. Lawrence, fruit growing is carried on to a considerable extent, and quantities of apples from this territory find their way to Montreal or are shipped to foreign markets; but on the interior lands, on the north side of the river, only the hardier fruits succeed, and the orchards are few and small. In Montreal and other cities and towns in this province, much taste is displayed in the laying out of the public parks and squares, and in the ornamentation of the grounds of the more wealthy members of the community. Horticultural societies and a Provincial Fruit Growers' Association have been organised, which are aided by provincial funds; annual exhibitions are held, and thus the love for the cultivation of fruits and flowers is fostered.

Ontario is the Banner province of the Dominion, and its wonderful variety of climate and rich horticultural possibilities are as yet but partially known. With the noble area of two hundred and twenty thousand square miles, and a population of two million one hundred and fifteen thousand, this province has twelve and a half million acres of cleared land, about three hundred and twenty thousand acres of which are under orchard, garden, and vineyard. The number of apple trees of bearing age in this province is about six millions, while there are three and a half million more of younger trees, most of which will soon be in bearing condition. The yield of apples in 1896 was very large, and is estimated at fifty-six million bushels. In the Niagara peninsula, and along the shores of the western part of Lake Erie peaches are grown very successfully, and there are said to be over half a million peach trees planted in that part of Canada. Grapes, also, are grown in immense quantities. There are about three million of bearing grape vines in Ontario, producing annually about fifteen million pounds of grapes. There are also large orchards of pears, plums, and cherries, so that Canadian markets are well supplied with home-grown fruits of excellent quality throughout the season, and a large quantity of apples is exported to Great Britain. During the past year more than two million barrels were exported from Montreal. Ontario also sends large supplies of fruit to the prairie districts in the west. A thriving organisation, known as the Fruit Growers' Association of Ontario, has been in existence for the past twenty-eight years, and has done much to stimulate fruit growing throughout the province, and also to cultivate a taste for ornamental trees, shrubs, and flowers. This association receives a liberal annual grant from the provincial funds. The large display of fruit and flowers at the leading annual exhibitions helps to draw further attention to these interesting and important subjects. The Ontario Government also gives annual grants towards the support of horticultural societies, which are established in most of the towns and cities of the province. Under this stimulus frequent floral exhibitions have been held, and the people have been led to vie with each other in beautifying their homes by the planting of trees and flowers, Many large floral establishments are well supported by lovers of flowers. In the cities and larger towns public parks have been established, valuable not only as health resorts, but as repositories for some of Nature's choicest arboreal gifts. Horticulture also forms an important part in the curriculum of the Ontario College of Agriculture, which is located at Guelph.

Manitoba and Columbia.

Adjoining Ontario at its western extremity is the province of Manitoba, with sixty-four thousand square miles of territory and a population of one hundred and fifty-two thousand. Here the climatic conditions are too severe to admit of the rapid extension of horticulture. The larger fruits are not successfully grown, but many of the small fruits are produced in abundance. The people are everywhere fond of flowers, and the long days and abundance of sunshine in the summer months give a wealth of bloom to many annuals and hardy perennials unknown in eastern climates. Westward of Manitoba lie the four organised territories of the Canadian North-West—Assiniboia, with an area of eighty-eight thousand square miles; Saskatchewan, one hundred and one thousand; Alberta, one hundred and five thousand; and Athabasca, one hundred and three thousand. These great divisions extend from the western boundary of Manitoba to the Rocky Mountains, are partly traversed by railways, which have opened up the country for settlement, and a sparse population of from fifty thousand to sixty thousand people is scattered here and there throughout this very large area. The love of trees, shrubs, and flowers is universal on the plains, and luxuriant gardens full of bloom are frequently found among the settlers. In the country to the north lie the unsurveyed and but partly explored districts, occupied only as yet by widely distant trading posts and occasional settlers, but mainly in possession of Indians and fur-traders. In this wide expanse are included the districts of Ungava, Keewatin, Franklin, Mackenzie, and Yukon, comprising in all about a million and a-half square miles, exclusive of the water areas.

The most westerly province, British Columbia, includes three hundred and eighty-two thousand square miles, and has a population of about one hundred and twenty-five thousand. In the busy mining districts not much attention is paid to horticulture, but west to the Coast Range of mountains, where the climate is mild and genial, much like that of England, fruits and flowers grow in profusion. There the holly, laurel, rhododendron, and yew flourish with the apple, pear, plum, and cherry, and in some localities, the peach. In those parts of the province between the Coast Range and the Rockies there are many fine valleys, some of which have not sufficient rainfall to admit of the successful cultivation either of grain or fruit without irrigation. There are, however, many mountain streams available for this purpose, and on some of the ranches very fine apples are grown. The taste for flowers is almost universal, and the long, mild season permits of many of them being grown in perfection. This province has also a Fruit Growers' Association, assisted by a grant from the public purse, and exhibitions of fruits and flowers are held annually in the larger towns and cities. Vancouver and Victoria have both very fine public parks.

Experimental Farms.

The progress of horticulture, as well as agriculture, throughout Canada has been greatly stimulated by the organisation and maintenance of experimental farms by the Dominion Government. Ten years ago this good work was begun, and while the greater attention has been given to measures looking towards the improvement of farming, many lines of horticultural work have been vigorously prosecuted. These experimental farms are five in number, the central or principal farm being located at Ottawa, the seat of government—where, on the boundary line between Ontario and Quebec, it serves the purposes of these two important provinces—and the four branch farms in the more distant provinces of the Dominion. A site was chosen for one of these at Nappan, in Nova Scotia, near the dividing line between that Province and New Brunswick, where it ministers to the needs of three Maritime Provinces; one was located near Brandon, in the central part of Manitoba; a third was placed at Indian Head, a small town on the Canadian Pacific Railway in Assiniboia, one of the North-West Territories; and a fourth at Agassiz, in the coast climate of British Columbia. The climatic conditions prevailing at these several points are all very different, and each location in this respect fairly represents a large area. At each of these farms, orchards and fruit plantations have been established, and a large number of varieties of fruits tested, while similar experimental work has been carried on with many different sorts of ornamental trees, shrubs, and flowers. The selections made in each case have been of such varieties as were thought to be most likely to succeed in the climates in which they were to be tried. In the Maritime Provinces the climate resembles that of many parts of New England, and the branch experimental farm at Nappan occupies a fairly representative position. The climate is milder and more moist than that of Ottawa, and all the varieties of trees and shrubs which succeed at the central farm do quite as well, or better, at Nappan, and many varieties of fruits which thrive in Nova Scotia are not able to endure the more severe winters at Ottawa. At this eastern branch farm there are now nearly four hundred varieties of large and small fruits under trial and about three hundred varieties of ornamental trees and shrubs, and most of these are making satisfactory growth. Many additions are made to these lists every year. Already these plantations are proving a useful guide to the people in the Maritime Provinces, whether they desire to grow fruit or to beautify their homes by ornamental planting.

(To be continued.)

THE WEATHER DURING THE WEEK ENDING APRIL 30, 1898.

STATIONS.	Temperature of the Air. Highest. Fahrenheit.	Temperature of the Air. Lowest. Fahrenheit.	Mean. Fahrenheit.	Mean. Centigrade.	Rainfall. In Inches.	Rainfall. In Centimetres.
London	60·9	29·7	48·3	9·06	0·49	1·24

The mean reading of the Barometer during the week at Greenwich was 29·60 inches, and that of the Thermometer 48°·3, the latter being 0°·3 below the week's average in the 50 years 1841—90. The direction of the wind was variable, the horizontal movement of the air being 13 per cent. below the week's average in the 16 years 1860—75. The duration of registered bright sunshine in the week was 23·9 hours. The measured rainfall amounted to 0·49 of an inch.

LAW.

A SEED TRADE DISPUTE.

THE case of Howcroft v. Laycock, tried by Judge Lumley Smith, Q.C., at the Westminster County Court a few days since, was interesting inasmuch as the [illegible]ing of his Honour goes a good way to prove that a seedsmen is absolutely protected by his non-guarantee clause. In this case Messrs. Howcroft, of Covent Garden, sued Mr. Laycock, of Midhurst, to recover £21 for seeds supplied him. This claim was admitted, but the defendant entered a counter-claim for £18 as compensation for losses sustained owing to alleged misrepresentation of some seeds supplied. The defendant stated that he purchased from the plaintiffs a two-pound packet of Couve Tronchuda; the seed was duly sown and all possible care taken of it, but the crop turned out to be strong-growing cabbages of the Jersey variety and not the dwarf Couve Tronchuda. The result was that defendant could not sell the crop. The plaintiffs showed that the seed was supplied under a non-guarantee clause, such clause having been inserted in catalogues, invoices, and advertisements. For the plaintiffs, Mr. Hayward said that all seedsmen sold their seeds under a non-guarantee clause; he considered the plants in question not an article of domestic use but used chiefly for cattle feeding.

Mr. A. F. Barron was present as an expert, and decided that the crop resulting from the seeds supplied was not of Couve Tronchuda. Judge Lumley Smith found that Couve Tronchuda was fit for human consumption, but that the plants resulting from the seed supplied by the plaintiffs was only fit for cattle. His Honour, however, considered plaintiffs protected by their non-guarantee clause, and so gave judgment in their favour both on claim and counterclaim, with costs. Defendant had leave to appeal.

NEW INVENTIONS.

The Improved Garden Hose.—The trouble experienced by many gardeners with garden hose bursting, kinking, or rotting, is met by another important improvement in this article by Messrs. Merryweather. This firm has been successful for years past in manufacturing durable garden hoses which shall last more than a season or two in regular work. The latest method of securing durability for their hose consists of an external coating of fine quality rubber of substantial thickness, which effectually prevents the canvas plies being soaked with water, as in ordinary hoses, and prevents rotting, which soon means the destruction of the hose. The ends of each length are also hermetically sealed with rubber to protect the canvas from water. To give flexibility this has an internal coating of the best and most pliable rubber, and thus kinking and consequent stoppage of the flow of water, causing bursts in the hose, is prevented.

OBITUARY.

MR. A. W. BLICK, who was formerly well known in horticultural circles owing to his position as foreman in the Royal Horticultural Society's Gardens at South Kensington, a position he held for a period of twenty-five years, died, we regret to learn, on the 2nd inst., at Brentford. For many years past Mr. Blick had been host of a comfortable inn near the Ealing Road, in the Middlesex county town, and here he was always ready to bring up old horticultural memories, while few men had a wider knowledge of R.H.S. affairs in connection with South Kensington. Mr. Blick passed away in his seventy-second year.

ANSWERS TO CORRESPONDENTS

Editorial communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, &c., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

Secretaries of horticultural societies are invited to send early notification of forth coming exhibitions and meetings, and are requested to advise us concerning change of dates

Diseased Dendrobiums.—T. G. O., Dulwich: We hope to answer your query in our next issue. Thanks for letter.

Rose Cultivation.—A., Bideford: The book you are searching for—"Rose Growing" by D. Gilmour—is published at 12, Mitre Court Chambers, Fleet Street, E.C.

Apples from Isle of Wight.—H. G.: Thanks for letter. You will have seen that the reply was given as early as possible (in our issue of April 30), for the GARDENERS' MAGAZINE goes to press on Wednesdays—see "Notice to Advertisers" on front page. However, you will now be able to take special care of the apple under consideration, and exhibit some selected fruits during the autumn, and an occasional dish at intervals during winter and spring to prove its fine keeping qualities. We suggest that you become a Fellow of the R.H.S. The subscription is one guinea per annum, and the literature you receive is alone well worth the money.

Gros Colmar Grapes.—J. S.: The failure of the young bunches to mature their flowers and set fruit is due, so far as we can gather from the tiny specimen sent, to weakness of growth following incomplete ripening of the wood last season. A badly drained border, or an excessive crop not properly fed, may have been the initial cause of failure; but with such little evidence, and no knowledge of the conditions under which the vines were grown, we cannot help you further. The rods of strong growing vines should be far enough apart to allow of the proper development of lateral growth and leafage. Permanent rods should be from four to five feet apart.

Annual Rose.—A., Bideford: Do not be in a hurry to throw away the pot in which the seed was sown, as, in the comparatively cool place you have for raising seedlings, germination will be slow. A warm pit is the best place for producing the seedlings, and these, as soon as large enough, should be pricke out and eventually potted into sixty-sixed pots. Under favourable circumstances the plants flower about two months from the time the seedlings are fit to handle. Cooler treatment should be accorded as soon as the plants are established in sixties. The rose to which you refer is only annual in the sense that it flowers within a year from seed sowing; it is really perennial, and is said to flower better as it grows older.

Gardening Associations.—W. B., Stockport: There is no central body to which your new society might become affiliated for the purpose of interchange of papers. Affiliation might be made with the Royal Horticultural Society, so that the literature it publishes could be utilised as a basis for discussions. The National Amateur Gardeners' Association offers many privileges to societies affiliated with it; its secretary is Mr. L. Brown, Brentwood, Essex. We do not make distributions of the kind you suggest, but your case is under consideration.

Weeds on Lawns.—C. R., Meopham: You will at this season have to resort chiefly to spudding for the removal of strong-growing weeds on lawns. Early in the spring or in the autumn are the best times for the application of lawn sand, and, though this is costly, it is most effective, killing out the daisies and other spreading weeds, and acting as a fertiliser to the grass. You had better root out all the dandelions, sorrel, and plantains as soon as possible, dropping a few grass and fine clover seeds into the holes thus left; then, early in the autumn, obtain some lawn sand through a horticultural sundriesman, and give the lawn a dressing. The following spring you will be more than satisfied with the results.

Carpet Bedding.—A. B., Bolton: The most comprehensive and freely illustrated work we know upon carpet bedding and summer bedding is one entitled "Album fur Teppichgärtnerei und Gruppenbepflanzung"; it is by Karl Göetze, and can be obtained from Ludwig Möller, Erfurt; the plans and illustrations are very liberal, and the names of plants are the same in Germany as elsewhere. If you do not care for so large a work, and object to anything "made in Germany," then there is the neat little pamphlet recently published by Messrs. H. Cannell and Sons, Swanley, Kent, for 6d.; it contains not less than sixty designs and abundant lists of plants for use in them.

Exhibiting at R.H.S. Meetings.—G. W. P., Middlesborough: You should intimate your intention of exhibiting at an R.H.S. meeting (May 10 is the next) by writing to the secretary, Royal Horticultural Society, 117, Victoria Street, S.W., stating that you wish to submit your plant to the Floral Committee for certificate. If you send the plant, asking that it be staged, nothing further will be necessary beyond instructions for its return. If you bring the plant you should apply to the secretary of the Floral Committee, at the Drill Hall, for an entry card. We presume you have compared your plant with others of its class and find it distinct; two discoloured leaves are insufficient to properly judge a plant upon. The following are the R.H.S, rules with respect to new plants, flowers, and fruits: They must in all cases be sent carriage paid and at the risk of the sender. A separate advice by post card or letter must be sent to the secretary, R.H.S. office, 117, Victoria Street, Westminster. Small parcels should be addressed to the secretary, R.H.S. office, 117, Victoria Street, Westminster. Very large or heavy parcels should be addressed to the Secretary, R.H S., Drill Hall, L.S.R.V., James Street, Victoria Street, Westminster; the postal advice being sent to the R.H.S. Office, 117, Victoria Street. Unless these regulations be complied with the risk of parcels going astray will be greatly increased. The following particulars should be communicated in writing: (1) The name and postal address of the exhibitor; (2) the name of the fruit, flower, plant, or vege-

HEATING APPARATUS.

table, and, in the case of seedlings, particulars as to parentage and date of raising should be given if possible; (3) if an importation, the name of its native country should be added. Seedlings sent without name will receive no award. We may add that the plant should arrive at the Drill Hall, James Street, early on any exhibition morning, as if it arrives later than half-past eleven a.m. it may not receive attention.

Grubs.—F. A. Uxbridge: The grubs sent are those of the Cockchafer or Rose Beetle. Lightly fork over the soil where possible and burn all the grubs that are turned up.

Daffodils from Seed.—S. K., Notts: Seeds should be sown as soon as perfectly ripe in pans of sandy loam. See that the receptacle is well drained, and that the compost is free from lumps; water must be given carefully through a rose, taking care not to keep the soil saturated. Place in a cold frame and put a piece of glass over the pan until germination takes place. Shelter must be given from strong sunshine and cold drying winds. During winter keep the seedlings near the glass and free from hard frost, but remember that daffodils are perfectly hardy, and so give plenty of air whenever possible. The seedlings may be transferred, when fit, to prepared borders of moderately light rich soil, not freshly manured however, or they may be planted from one half to an inch apart in a cold frame, so that protection may be afforded when such is deemed necessary. Two year old bulbs will still be very tiny, and need not more than an inch of space, but after this the bulbs will commence to swell, and as the seasons recur more room and hardier quarters must be provided, though wind screens should always be allowed. When the seedlings first flower they will probably not show to advantage, so it is always best to retain them for two or three years more until a strong bulbs gives a fully developed flower, by which it may be judged. We know of no book on the subject, though much of the information contained in "Ye Daffodyl," to be obtained from Messrs. Barr and Sons, 12 and 13, Covent Garden, London, would prove useful to you. Its price is 1s.

Names of Plants.—R. S. H., Wexford: 1, Primula viscosa; 2, P. verticillata; 3, P. cortusoides; 4, a florists' form of P. auricula.

W. C., Carlow: 1, Fritillaria delphinensis; 2, Dicentra cucullata, probably, flowers were all spoiled; 3, Geum rivale; 4, Epimedium alpinum; 5, Kerria japonica fl. pl.; 6, Boussingaultia baselloides.

A. B., Fawley: 1, not recognized, send in flower; 2, Berberis Darwini; 3, Fritillaria lutea; 4, Dielytra spectabilis; 6, Fittonia argyroneura.

E. A. M., Darlington: 1, Exochorda grandiflora; 2, Cheiranthus mutabilis; 3, Doronicum plantagineum excelsum; 4, Phlox divaricata.

A. F. F., Ripon: 1, Odontoglossum cirrhosum; 2, O. Rossi majus; 3, Trichopilia suavis; 4, a very poor form of Cattleya Mendelli.

ENGAGEMENTS FOR THE ENSUING WEEK.

MEETINGS.

Tuesday, May 10.—Royal Horticultural Society: Committees meet at 12 o'clock. Demonstration at 3 p.m. by Rev. Prof. Henslow, on "Some Plants Exhibited."

Wednesday, May 11.—Royal Botanic Society's Summer Show at Regent's Park. National Tulip Society: Exhibition to be held at Regent's Park, in conjunction with the Royal Botanic Society's Show.

Friday, May 13.—Royal Botanic Society's Lecture.

AUCTION.

Tuesday, Wednesday, and Friday, May 10, 11, and 13.—Orchids, Japanese Lilies, Ferns, Latanias, Seaforthias, Coryphas, Geraniums, &c, at Protheroe and Morris's Rooms.

MARKETS.

Covent Garden.

There are fairly good supplies of most kinds of produce. The choicer green vegetables, apples, and oranges realise high prices; for new potatos and vegetables there is a keen demand. Cut flower trade brisk throughout.

Fruit.—Tasmanian apples, 10s. to 16s.; Californian, 8s. to 11s. per case; N Scotian, 15s. to 25s. per barrel; English grapes, 3s. to 4s. 6d.; Channel Islands, 3s. to 4s.; Dutch, 2s. 6d. to 3s. 6d. per lb.; pineapples, 2s. 6d. to 4s. 6d. each; bananas, 5s. to 9s. per bunch; Valencia oranges, 12s. to 25s. per case; Jaffa, 10s. to 12s. 6d. per box; lemons, 8s. to 15s. per case.

Flowers.—Arums, 2s. to 4s.; carnations, 1s. to 3s.; eucharis, 3s. to 4s.; gardenias, 1s. to 3s.; Lilium Harrisi, 2s. to 4s.; tea roses, 6d. to 1s.; pink roses, 3s. to 6s.; red roses, 2s. to 4s.; cattleyas, 6s. to 9s.; Odontoglossum crispum, 1s. 6d. to 4s.; and tuberoses, 1s. to 1s. 6d. per dozen blooms; Adiantum cuneatum, 4s. to 8s.; marguerites, 2s. to 4s.; narciss, various, 1s. 6d. to 3s.; daffodils, 1s. 6d. to 4s.; tulips, 3s. to 6s.; mignonette, 2s. to 4s.; pelargoniums (scarlet), 4s. to wallflowers, 2s. to 3s.; polyanthuses and cowslips, 1s to 1s. 6d.; primroses, 9d. to 1s.; bluebells, 9d. to 1s.; and violets, 9d. to 3s. 6d. per dozen bunches; azaleas, 6d. to 9d.; stephanotis, 4s. to 6s.; lily of the valley, 6d. to 1s.; and pelargoniums, 4d. to 8d. per dozen sprays; bouvardias, 6d. to 8d.; white lilac, 2s. to 3s. per bunch.

Vegetables.—English tomatos, 8d. to 10d. per lb.; Canary, 1s. 6d. to 2s. per box, 3s. 6d. to 4s. 6d. per case; English spring, onions, 2s. 6d. to 3s. per dozen bunches; Egyptian, 6s. to 7s. per bag; rhubarb, 2s. to 3s. per dozen bunches; seakale, 6s. to 9s. per dozen punnets; asparagus, 1s. to 7s. 6d. per bundle; cabbages, 3s. to 4s. 6d. per tally; spinach, 2s. to 3s. per bushel; mushrooms, 6s. to 8s. per 12 lb.; cauliflowers, 1s. to 2s. per dozen; broccoli, 3s. 6d. to 6s. per crate; endive, 1s. 4d. to 1s. 8d.; lettuce, 9d. to 1s.; cos, 2s. to 2s. 6d.; cucumbers, 2s. 6d. to 5s. 6d. per dozen; French beans (Madeira), 3s. to 4s. per basket; new carrots, 6s. to 8s.; turnips, 6s. to 8s.; mint, 4s. to 5s.; and parsley, 1s. 6d. to 1s. 9d. per dozen bunches; Canary new potatos, 8s. 6d. to 12s.; Algiers, 10s. to 14s.; Malta, 6s. to 10s. per cwt.; French kidneys, 2d. per lb.

Borough Potato Market.

The home supplies of potatoes seem to be almost exhausted owing to the long-continued steady demand. Many sorts do not now appear upon the market, but English and Scotch varieties in good condition have advanced in price from 5s. to 10s. per ton. importations from Belgium and Germany have also advanced 3d. or more per bag.

EPPS'S COCOAINE.

COCOA-NIB EXTRACT.

The choicest roasted nibs (broken-up beans) of the natural Cocoa on being subjected to powerful hydraulic pressure, give forth their excess of oil, leaving for use a finely-flavoured powder—"Cocoaine," a product which, when prepared with boiling water, has the consistence of tea, of which it is now, with many, beneficially taking the place. Its active principle being a gentle nerve stimulant, supplies the needed energy without unduly exciting the system. Sold only in labelled Tins. If unable to obtain it of your tradesman, a tin will be sent post free for 9 stamps.

JAMES EPPS AND CO., LTD.,

WEST'S
PATENT
IVORINE
PLANT LABELS
NAME TO BE WRITTEN ON WITH ORDINARY LEAD PENCIL OR PEN AND INK.

THE "IVORINE" WRITING DISC

Being made of a specially prepared substance, having the properties of real ivory, is imperishable, and does not corrode or eat away, like wood and metal labels; and being ivory-white, when written upon it shows to perfection. And also, as the writing is on the Ivorine itself it is permanent, though washable, and does not become unreadable, as is the case with all painted labels, as the paint gets old. It is for all purposes, and will last a century, either in a greenhouse or out in a garden, and not only is it always ready for use, and may be written on both sides, but the name when written in pencil may be easily rubbed off, and so used as many times as desired.

Samples and Lists of the West's Patent Specialities post free.
Price, **9d.** per dozen; **8s.** per gross, Carriage Paid.
Supplied by all Nurserymen, Florists, &c.

The LEEDS ORCHID Co.,
ROUNDHAY, LEEDS.

STANDEN'S MANURE.

TRADE MARK.

ESTABLISHED OVER 30 YEARS.

Exceeds all others in General Fertilising Properties and Staying Powers.

Promoting a rapid, healthy, and robust growth to plants generally.

It is a clean and dry powder, with very little smell.

Its highly fertilising properties render its money value, in comparison with other Manures, at least double, very small quantities will produce favourable and lasting results.

ANALYSIS ON APPLICATION.

Sold in Tins, **1s.**, **2s. 6d.**, **5s. 6d.**, and **8s.** each, and in Kegs, well secured to prevent loss through exposure, 28 lbs., **10s. 6d.**; 56 lbs., **18s.**; 112 lbs., **32s.**

To be had from all Seedsmen and Florists.

THE PUBLIC HEALTH

DEPENDS LARGELY ON THE PURITY OF FOOD.

Beware of Mixtures.—"We cannot imagine that our ideal pure Cocoa—a perfect food in itself—can be improved by such additions (as Kola and Hops). In fact, we are of opinion that its dietetic value would be altered, and that it would become a medicinal preparation."—*Guy's Hospital Gazette.*

"**Kola** is a drug pure and simple."—*Epicure.*

"**Kola is not harmless.**"—*Medical World.*

CADBURY'S Cocoa is Absolutely Pure.

CADBURY'S

Cocoa is the most sustaining beverage for brain fatigue and for muscular force.

"Consumers should be supplied with a dietetic article whose purity is unquestioned, and without doubt this essential quality is the characteristic virtue of Cadbury's Cocoa."

—*Public Opinion.*

NANSEN.
Cadbury's

CADBURY'S

Cocoa stands among the highest, if it has not attained the first place for its purity. According to analysis it stands head and shoulders above all other Cocoas."—*To-Day.*

"The name of Cadbury may always be accepted as an unimpeachable guarantee of excellence."—*Happy Home.*

When you ask for CADBURY'S Cocoa see that you get it, as commoner and mixed qualities are often pushed for the sake of extra profit.

NOTES OF THE WEEK.

PREVENTION OF CLUB-ROOT.

DURING the past two years experiments have been conducted by Professor Gilchrist, director of the agricultural department of the University Extension College, Reading, with a view to the prevention of the disease known as finger-and-toe and club-root, and have obtained some interesting results. From the official report it appears that in conducting some rotation experiments at Headington, near Oxford, in 1895, it was found that the swedes which formed the first crop were badly infested with club-root, and that in some parts of the field the crop was practically destroyed. The soil of the field is sandy, resting on limestone rock, and in various parts differs materially in its percentage of lime, this difference being to a considerable extent coincident with the damage done by the disease. Soil from two parts of the field was analysed, and where the crop was fairly free from disease, the lime was equal to 5·49 per cent., where the crop was much damaged the soil contained only ·45 per cent. of lime. This fact is of importance as illustrating the great value of lime, as we have so frequently pointed out, in checking the development of the slime fungus which causes the disease. In the following year a portion of this field was marked off into eleven parts, and ten of these were dressed, three with caustic lime in varying proportions, two with sulphate of copper, two with gas-lime, one with chalk, and one with basic slag. The dressings, with one exception, were applied in January, and one of the applications of sulphate of copper was made just before sowing the seed. The report states that "in 1896 none of the dressings had any appreciable effect in reducing the ravages of the disease. It would, in fact, appear from the table given in the report that the dressings assisted in the development of the disease for on the undressed plot the sound roots were at the rate of 5 tons 6 cwt. per acre, the slightly diseased 4 tons 16 cwt., and the badly diseased 2 tons 1 cwt. In no other plot was there the same weight of sound roots, the nearest approach being the plot dressed with gas lime at the rate of three tons per acre, and here the sound roots were at the rate of 5 tons 4 cwt. per acre, the slightly diseased roots 10 tons 18 cwt. and the badly diseased 18 cwt. In none of the dressed plots was the weight of diseased roots less than 9 tons, a fact difficult to understand. In view of the results obtained in 1896 it was decided to again grow swedes and turnips on the same plots in 1897, without any further dressing, to ascertain whether results might be obtained by giving the dressings a longer time to act in disinfecting the soil, and the report states that "all the forms of lime, viz., caustic lime, gas lime, and chalk, gave excellent results." The figures given support this statement, but unfortunately the table is prepared in a different manner and the crop is divided into two portions, good and bad only. In 1897 the crop on the undressed plot dwindled down to 16 cwt., and all the roots were bad. All the roots were also diseased on the two plots dressed with 2 cwt. of sulphate of copper, the crop on that dressed in January being 1 ton 10 cwt., and where applied in spring 10 cwt. The results obtained from the dressing of gas-lime at the rate of one ton per acre, was very unsatisfactory, for the total crop amounted to 2 tons 14 cwt. only, of which 1 ton 10 cwt. were diseased. These figures are perplexing, and should admit of further explanation, for with a dressing of three tons of gas-lime, there was a crop of 11 tons 6 cwt., of which 10 tons 16 cwt. were sound. The plot dressed with 2 cwt. bleaching powder gave 3 tons 6 cwt per acre, of which 6 cwt. were diseased, against a crop in 1896 of 12 tons 3 cwt., of which 10 tons 14 cwt. were diseased. Basic slag gave somewhat peculiar results, for in 1896 the plot which received a dressing of this fertiliser at the rate of 10 cwt. per acre, produced a crop of 13 tons of which 3 tons 14 cwt. were sound, whereas in 1897 the total crop was 5 tons 4 cwt., with 4 tons 12 cwt. sound. The best results were obtained from the dressings of two tons caustic lime, and of four tons of chalk, which gave 17 tons 4 cwt. and 14 tons of sound roots respectively, while three tons of gas-lime and one ton of caustic lime sufficiently satisfactory to justify their use.

YUCCA FERTILISATION.

MR. C. LLOYD MORGAN'S description of the method of fertilisation of the yucca involves such a purposeful action on the part of the moth concerned (*Pronuba yuccasella*) as to differentiate it altogether from the general category of insect fertilisers. In the vast majority of cases, the transfer of the pollen by insect agency from one bloom to another, or one plant to another, is effected altogether blindly; the flowers are visited for the sake of the honey, or, it may be, for the sake of the pollen itself, and as cross-fertilisation is a distinct benefit in most cases, evolution has brought about a myriad cunning lures and devices through which the visitor is made the involuntary carrier of the potent grains from point to point of vital activity. So far as the actual object or effect of these grains is concerned, the insects are as unwilling as the breezes which effect the same essential operation with plants, which, devoid of insect attraction, scatter their redundant pollen crop to the four winds, and find their mates in the wings of the zephyr instead of the bee. This moth, however, goes as systematically to work as the most skilful gardener, and having collected the needful grains of pollen from one flower, packing them carefully into a ball for easier porterage, she flies off with this to another blossom, and carefully applies it in precisely the right place in the stigma which apparently has been so shaped as to facilitate the reception of the pellets. There is no suspicion of accidents; she does exactly the right thing, no more and no less, to ensure cross-fertilisation of that particular flower in the most effectual way possible, and for the particular benefit of the yucca plant itself. "Nothing for nothing," however, is obviously the moth's motto, and she has already arranged a cunning system of taxation through which the yucca community so brought into possible existence, shall pay toll to her descendants as a *quid pro quo.* At the bottom of that stigma lies the ovary of the flower, the future cradle of its new generation, and Mistress Pronuba, prior to putting the finishing touch of fertilisation to the future brood, pierces the ovary wall and gently inserts, cuckoo fashion, her own eggs to bear it company. Now begins a sort of race between the pollen grains above and the hatching eggs below; the former push their slender tubes down through the length of the stigma, and so reach the yucca eggs. These swell and speedily begin to be seeds proper, when lo! their small companions burst their shells, and the toll-taking begins and continues at the expense of the yucca brood, until that of the moth is ready to be launched forth into the world and begin another cycle. The clever moth and mother has, however, been provident enough to arrange for a margin beyond the toll exacted by her youngsters, and equitably leaves fifty per cent. of the yucca brood intact, as her partner's share in the joint transaction, so that fair provision is made for the continued existence of both. Carefully considered, this instance of co-operation between insects and plants is seen to be very wonderful; and it is excessively difficult to imagine how the fashioning and transfer of the pollen pellets by the moth has been brought about, especially seeing that in a flower like that of the yucca, the apex of the stigma is a long way from the ovary, and requires a special visit.

PLANTING ROSES IN SPRING.

AUTUMN planting, when carried out under proper conditions, invariably gives such good results in the rose garden that there is a tendency in some quarters to regard the autumn as the only season in which roses can be successfully planted, and consequently to overlook the opportunity the spring months afford for the formation of new beds and borders of roses, and for filling gaps in those which have been in existence for a considerable period. Autumn is unquestionably the best season in which to plant roses, and should as far as practicable be taken advantage of, but it is not the only one in which planting operations can be performed with success, and it is evident from our correspondence that some reference to the spring planting of roses will be useful to many of our readers. It is, of course, a matter of common knowledge that with special care roses may be transplanted until March is well advanced with the assurance of a satisfactory growth in the season following, but it is not so generally known that plants previously prepared in pots give the best possible results when planted in May. Well-established plants in five or six inch pots are by no means costly, and they may give some excellent blooms late in the season, and will assuredly in the year following surpass in the abundance and quality of their flowers those planted in the autumn; with novelties, it is a decided advantage to obtain plants and bed them out in May, because of the liberal supply they will give of buds for propagating purposes in the course of the summer. In the case of the delightfully fragrant and exquisitely coloured tea-scented varieties, planting in May has much to recommend it, and we would strongly advise those who propose to extend their culture to obtain plants in pots and bed them out at once. The only objection to the practice of forming beds with pot plants is the additional cost of carriage, but this of course will only apply when they have to be obtained from a distance, and in no case will it be found excessive. Plants in growth necessarily require rather more care than those received in a dormant state; and when received from the nursery they should be placed in a frame and carefully hardened, as success will materially depend upon the plants being so thoroughly prepared that when bedded out they are well able to bear the effects of unfavourable climatic conditions without injury. To properly prepare the beds is not less necessary than to have well-hardened growth, and to assist the roots to push freely into the new soil, it is an excellent practice to fill in about the balls with a light rich mixture from the potting shed. Supplying the plants with water until they have become established, and other details, will suggest themselves to the cultivator, who may be assured that he will obtain ample return for the care he bestows upon the plants until they are well established in their new quarters.

FRUIT AND VEGETABLE IMPORTS.

The Board of Trade returns for April are hardly so satisfactory as could be wished, more particularly in the matter of exports. In the imports there is an increase equal in value to 14·5 per cent., but in the value of the exports there is a material drop, this being equal in the case of British and Irish produce to 11·1 per cent., and in foreign and colonial merchandise it is equal to 16 per cent. The increase in value of the imports is to a considerable extent due to the greater receipts of cereals and at higher prices. The increases in the value of the products of the garden and orchard are about equally balanced, the two most marked features being the increase in the supplies of potatos and the shrinkage in the apple supply. The imports of apples amounted in the aggregate to 167,121 bushels, of the value of £73,718, or a drop of 169,213 bushels in quantity, and of £21,789 in value. For the four months there has been a drop of 1,058,000 bushels as compared with the same period of last year. The figures of 1896 are of interest as showing the appreciation in the value of these fruits, for, although the quantities received exceeded this year's supplies by 61,000 bushels, the value is returned at £40,000 less. Cherries, of which 331 bushels were imported in 1897, have no place in last month's returns. Plums, on the other hand, were absent from the returns of April, 1897, but this year one bushel appears to have been received, and this is entered at the value of £2. The imports of pears was somewhat smaller than last year, the aggregate being 1,355 bushels of the value of £743, or a decrease of 25 bushels and £104 in quantity and value respectively. Augmented supplies of grapes were received, the aggregate imports being 2,259 bushels, of the value of £2,694; but on the four months ending April there is a material decline. The imports of unenumerated fruits continue to increase, and their value for the month is £34,406, and for the four months £126,505. The increase in the imports of potatos was even more marked than the decrease in the supplies of apples, for during the month they amounted to 1,186,653 cwt., of the value of £275,630, or an increase in quantity of 1,100,486 cwt. and in value of £234,663. Germany appears to have benefited the most materially from the failure of the potato crop in the United Kingdom last year, for the growers in that country sent us in April 147,037 cwt., against 99 cwt., and in the four months 1,359,215 cwt., against 2,323 cwt. in the corresponding periods of last year. The gain of Germany in money is for the current year £290,269. France has benefitted to the extent of about £50,000, and "other countries" to the extent of £240,000 from the disastrous results of our potato harvest in 1897. In round figures, we have paid during the past four months £600,000 more for potatos than in the two preceding years, and these indicate in some degree how heavy were the losses of cultivators. On the other hand, onions were imported in lessened quantities, the aggregate being 613,633 bushels, and it is interesting to observe that, with a decrease of 23,584 bushels, there is an increase in value of £18,726.

Town Trees.—Of the many improvements that have been made during the second half of the present century, not the least important is the planting of trees in towns. It was long an article of general belief that it was practically impossible to successfully cultivate any of the various forms of arborescent vegetation in smoky towns, but more recent experience has brought into strong relief the fact that while some trees rapidly succumb when exposed to the adverse influence of a smoke-laden atmosphere, others, such as the lime and the plane, will flourish in smoky towns. As the result, large numbers of trees have been planted in the streets, and in many instances they make so satisfactory a growth as to form a pleasing relief to the bricks and mortar, and provide acceptable shade. On the other hand, there are many cases where the trees do not succeed so well as could be wished, in consequence of the rough usage to which they are subjected. Smoke is not the only enemy with which town trees have to contend; in some cases the soil is rendered unfit for promoting a healthy root growth; and in others the heads are mutilated under pretence of pruning. Another enemy is the young rough, who appears to derive an immense amount of pleasure in the destruction of trees that are not of sufficient strength to resist his efforts. As the practice of injuring young trees appears to be on the increase, it is satisfactory to have evidence that the magistrates are beginning to more fully recognise their responsibilities in the matter. At King's Heath the other day the bench awarded a punishment of two months with hard labour, and it is reasonable to assume that the trees in the district will enjoy immunity from injury for some time to come. Similar severity is needed in the suburbs of London, for no sooner is a road planted than some of the trees are more or less injured.

Apple Scab in New Zealand appears to cause fruit growers a good deal of trouble; so much so that the government of the colony has issued a pamphlet prepared by Mr. T. W. Kirk, Government biologist, illustrating the disease, and indicating remedies. A full strength dressing of Bordeaux mixture is advised just as the buds begin to swell, and another weaker dressing after the fruit has set. For an attack late in the year a solution of carbonate of copper is recommended, but this should not be given if the fruits are approaching ripeness owing to the poisonous properties of copper.

The Lady Gardener appears to have given rise to considerable apprehension in some quarters, and one of the horticultural associations has sent to *Truth* a protest against the assumption that a woman can receive a sufficient training in three years to fit her for the position of a head gardener. The association making the protest observes: "If it were a question of the young lady in the florist's shop, or any similar position, we should not attempt to lodge the protest which we ask your permission to do, but when it is reported that a woman has, in the space of three years or so, acquired all the knowledge necessary to take charge of a well-kept public or private garden in all its cultural details, we confess we wonder whether this is a fact or a fiction going the round of the Press. To make a practical gardener it is necessary for the individual to pass through all the various stages of work, including digging, trenching, and other laborious items, and no one can be a competent and qualified judge of good workmanship, and the time required for each operation and other details, without such experience. The work of a gardener is most heavy and laborious. He has to work in the open air under all sorts of climatic conditions, and he has to endure frequent changes of temperature from the hot-house to outside departments, which we find require a constitution of iron to stand. In our opinion the time has arrived when it behoves every gardener to make himself heard individually and by organisation in defence of his profession." There will be no harm in the gardener expressing his opinion upon the question at issue, but it is undesirable that concerted action should be taken with a view to preventing lady gardeners obtaining employment irrespective of any ability they may possess. We, however, are strongly of the opinion that were it desirable, there would be no necessity for such action, as the gardener has nothing whatever to fear from the competition of the lady gardener. Certain operations are well within the compass of an intelligent woman, but, as a whole, the work of the garden is, as pointed out in the protest, so heavy that very few women are physically fitted for it, and their thorough training in practical details, by which alone proficiency can be obtained, is out of the question.

West Indian Mangosteen are likely at no distant date to be regularly imported into this country. The mangosteen is a native of the Molucca Islands, and is cultivated in the Straits Settlement, Java, and in one or two localities in India and Ceylon. The fruit is regularly shipped from Singapore to the Calcutta market. Plants of this well-known tropical fruit have been widely distributed from Kew to the West Indies, and the first West Indian fruits were produced at the Botanic Gardens, Trinidad in 1875. In September, 1891, the Governor of that island forwarded some West Indian mangosteens for presentation to Her Majesty the Queen. The mangosteen fruited for the first time in the Jamaica Botanic Gardens in 1886 (*Kew Bulletin*, 1895, p. 79). Last year a box was received at Kew from Mr. J. H. Hart, F.L.S., of Trinidad, containing nine fruits of mangosteen, which were perhaps the first to reach this country in a condition to allow their merits to be appreciated. Each fruit was separately packed in a compartment with pine wool. Owing to the firm consistency of the outer wall of the fruit, it appears to travel well. The fruits were distributed to the Secretary of State for the Colonies and others. The reports received were uniformly favourable. One fruit was sent to Mr. George Munro, one of the leading fruit salesmen in Covent Garden, to obtain an opinion as to prospects of shipments of mangosteens to this country. Mr Munro replied: "I cut open the fruit and showed it to some of my best customers, and they think with me that if they came in good condition and not too many at first, a business could be worked up in them. At any rate, I should like to try some, and if sent, will do all I can to get a trade for them. They appear to be a fruit that would carry well."

A New Botanic Garden for Ghent.—The burgomaster of the famous city of Ghent recently stated that the municipality proposed to make several new arrangements in connection with its public parks and gardens. The most important item is the proposed creation of a new and extensive botanic garden that will be of great value to the large horticultural community of the city and surrounding districts.

The Nitrogenous Nutrition of Flowering Plants formed the subject of a paper recently read before the Paris Academy of Sciences by Mons. L. Lutz. It was shown that nitrogenous nutrition could be supplied by means of amines, salts of ammonium compounds, and alkaloids. The amines can be assimilated directly without being previously converted into ammoniacal salts or nitrates; those of low molecular weight are the more easily taken up by the plant. Amines unite with acids to form salts and give a strong alkaline reaction like ammonia.

Flora of Mongolia.—Mr. and Mrs. Littledale have made another adventurous journey into the heart of Central Asia; this time to North-western Mongolia, by way of Siberia. Mrs. Littledale made an excellent collection of dried plants, which has been presented to Kew; this comprises between two and three hundred species. Although there are probably few, if any new species, the specimens are specially valuable on account of the admirable care with which Mrs. Littledale has prepared them. In all cases where it was possible the entire plant, including root, was procured. Few professional collectors, state the authorities at Kew, take as much pains as Mrs. Littledale has done.

The Record of the Weather for the first quarter of the year is of exceptional interest. According to the observations made at the Royal Observatory, Greenwich, the mean reading of the barometer was 29·875 inches, being ·100 inch above the average reading in the first quarters of fifty-seven years; the mean reading was ·384 inch above the average in January, ·041 inch below in February, and ·042 in March. The mean temperature of the air was 41·5 degrees, or 2·6 degrees above the average in the first quarters of one hundred and twenty-seven years; it was 6·9 degrees above the average in January, and 2·4 degrees above in February, but was 1·4 degrees below the average in March. In January the weather was generally dry, mild, and dull; in February it was still mild and dull, but with frequent rain; in March, with the exception of a few warm days in the middle of the month, it was cold. At Greenwich, March was the coldest and January was the warmest month in the quarter, the mean temperature in January having been 2·4 degrees higher than in February, and 3·8 degrees higher than that in March. At twenty-seven other stations of observation the mean temperature of the air during the quarter ranged from 38·7 degrees at Llangammarch Wells, 39·3 degrees at Wolverhampton, and 39·5 degrees at Halifax, to 43·7 degrees at Ventnor and at Llandudno, 44·9 degrees at Truro, and 45·1 degrees in Guernsey. The amount of rain measured during the quarter at the Royal Observatory was 3·24 inches, which is 1·71 inches below the average in the first quarters of eighty-three years. The amount was 1·20 inches below the average in January, 0·35 inch below in February, and 0·16 inch below in March. At twenty-seven other stations of observation the rainfall during the quarter ranged from 2·48 inches at Oxford, 2·53 inches at Hereford, and 2·66 inches at Coventry, to 6·28 inches at Halifax, 8·02 inches at Llangammarch Wells, and 14.31 inches at Stonyhurst. The duration of bright sunshine recorded at the Royal Observatory was 156·9 hours, being 17·3 per cent. of the total hours during which the sun was above the horizon, against a mean proportion of 18·5 per cent. in the twenty preceding first quarters. The duration of bright sunshine was 9·9 per cent. below the average in January, and 18·2 per cent. in March, while in February it was 21·1 per cent. above the average.

Visitors to Kew During 1897 numbered 1,239,683, or a falling off of 157,192 from the total of 1896, and of 191,982 from the average attendance for 1887-96. Sunday visitors numbered 485,544. The maximum attendance for one day was 84,431, on June 7; and the lowest, 57, on March 18. The monthly returns for 1897 are January, 12,961; February, 36,124; March, 50,438; April, 169,090; May, 165,036; June, 218,184; July, 187,622; August, 219,650; September, 95,729; October, 55,160; November, 19,254; December, 10,435.

Old Kewites will be interested to hear that Mr. Robert Pantling has been appointed deputy superintendent of the Cinchona Plantations, Sikkim, in succession to Mr. J. A. Gammie, now retired. Mr. J. H. Holland, formerly assistant-curator of the Old Calabar Botanic Station, has been appointed by the Secretary of State for Foreign Affairs to succeed the late Mr. Horace Billington as curator there. Mr. Walter Haydon, who for four years has been curator at the Gambia Botanic Station is now curator of the Sierra Leone Botanic Station on the West Coast of Africa.

Coffea stenophylla at Trinidad.—The Highland Coffee of Sierra Leone (*Coffea stenophylla*) has been widely distributed to tropical countries from Kew by means of seeds and plants. At Trinidad, at only a few feet above sea-level, it has recently fruited, and Mr. J. H. Hart, F.L.S., superintendent of the Botanic Gardens of that colony, has made the following interesting report, which appears in the current *Kew Bulletin*: Some four years ago we received a new kind of coffee from Kew. This has now fruited for the first time, four years from seed. The trees are in robust health, and have given for a first yield a very fair return. This coffee is quite distinct from anything hitherto grown in the West Indies, and appears likely to develop into a valuable minor product. The berries, instead of being red when ripe, as in the Arabian varieties, are a dark purple, and the bean is small and attractive looking. When dried and cleaned it has much the appearance of the finest Mocha. The flavour when made into a cup of coffee is excellent, being fully equal to the finest Arabian, from which there is little to distinguish it in appearance when prepared in the same way. The trees are much more vigorous than Arabian coffee; they have a small, dark, shiny leaf, but the individual branches are somewhat smaller than those of Arabian, and very much less robust than Coffea liberica. Our trees are now eight feet in height, and would appear to be willing to go higher if we would let them. So far as our experience has gone with Coffea stenophylla there is good reason to hope that it will prove a valuable introduction.

Potato Culture in Ireland.—Several of the leading railway companies in Ireland are making concessions with a view to assisting farmers in checking the spread of the potato disease. The concessions are free carriage, at owner's risk, of potato-spraying powder and spraying machines during the present season. The Messrs. Strawson, well known as makers of fungicides and insecticides, have been the chief means of inducing the companies to make these efforts towards the reduction of the dreaded disease. The companies making the concessions are the Midland, Great Western, Belfast and Northern Counties, and the Great Northern Railway Company of Ireland.

Messrs. Mackenzie and Moncur's Works at Edinburgh were severely damaged by fire on the night of May 11. The horticultural buildings, factory, and engineering works suffered, it is estimated, to the extent of £25,000. It is presumed that the fire broke out in the boiler room; it spread rapidly, and was with difficulty confined to the establishment of Messrs. Mackenzie and Moncur.

Artificial Manures in Germany are used on a most extensive scale by both horticulturists and agriculturists; indeed, it is stated on good authority that four times the amount of these are used in Germany than in France. The result of this use and high methods of culture in other directions is that it now seems practically impossible to raise the fertility of the soil any higher.

Rev. H. H. D'ombrain's Birthday.—There was an exceptionally large gathering at the monthly dinner of the Horticultural Club on Tuesday, for so high is the estimation in which the Rev. H. H. D'ombrain is held that the whole of the members, with the exception of a few who were prevented by illness or were from home, were present to take part in the celebration of his 80th birthday. Sir John T. D. Llewellyn, Bart., M.P., presided, and in proposing Mr. D'ombrain's health spoke at some length of the eminent services he had in the course of his long and active life rendered to horticulture. Sir John said that as the founder and the honorary secretary of the Horticultural Club Mr. D'ombrain had rendered services of special value and had endeared himself to all the members as proved to demonstration by the large attendance, and by the unanimity with which the suggestion that the members should mark their appreciation of his services by presenting him with a birthday gift had been acted upon. It was, not as Sir John Llewllyn said, possible to recognise such services by a presentation of money, but such presentation was evidence of esteem, and the whole of the members had united in contributing an equal share to the purse which he had great pleasure of of presenting to Mr. D'ombrain as a birthday gift. They had no lady members and therefore the ladies had not been able to contribute to the contents of the purse; but the purse itself had been contributed by a lady who was especially anxious to share in the pleasure they all had in making the presentation. That the toast was received with great heartiness follows as a matter of course, nor is it surprising that Mr. D'ombrain should have been visibly affected by the hearty demonstration. In acknowledging the expression of kindness on the part of the members of the club, he said he regarded with pardonable pride the remarkable gathering. Many of those before him he had known for upwards of thirty years, others were more recent friends, and he was immensely gratified to find that the places many of his old friends, now gone to their rest, had occupied in the world of horticulture and in his heart, were filled by their sons. He could not anticipate an indefinite future, but he hoped he might have the pleasure of meeting the members on many future occasions. Mr. G. Munro, who had acted as treasurer, having briefly referred to the promptitude with which every member had replied to his communications, the formal proceedings were concluded, and the remainder of the evening was spent in social intercourse. There was a large attendance at the meeting of the committee of the National Rose Society in the afternoon, and at this also Mr. D'ombrain received the heartiest congratulations.

The Old Poplar Tree at Chiswick that had become well known to travellers along the Chiswick High Road, by reason of its enormous size, succumbed to the gale of Thursday, the 11th inst., and in its fall damaged Blandford Lodge, a private residence on the opposite side of Marlborough Road to which the tree stood. This tree is well known to be over two hundred years old, and is supposed to have been one of a series that formed a fine avenue that extended to the river-side in the days when Turnham Green was a broad, open common.

Packing Tomatos for Sending Long Distances.—Mr. W. Neild gives some useful advice on packing tomatos for sending long distances, in the current issue of the R.H.S. journal. He states in the course of his observations that large quantities of fruit are destroyed by bad packing. In many instances the fruit is placed loosely several layers deep in baskets or boxes, with the result that in most cases it arrives at its destination in a bruised and damaged condition. The best system of packing is to place the fruit in a single layer in shallow boxes. The boxes should be strong and light, holding from ten to fifteen pounds each; and when a larger quantity is to be sent away a number of boxes should be placed on the top of each other, and fastened together with strong cord. A little soft hay, dry sphagnum moss, or wood wool should be placed in the bottom of the box, and on this a covering of soft white paper. The fruit should be packed closely together, stalk end downwards. When the box is full or the requisite quantity put in, the fruit should be covered with paper and all vacant spaces filled with the packing material before the top is put on. Too much emphasis cannot be laid upon the absolute necessity of packing the fruit firmly, to prevent it moving about, as it would thereby become damaged. Neither grass nor any damp material should be used for packing tomatos, for if they remain in the boxes for several hours, heating or fermentation takes place, which materially injures the quality of the fruit. When tomatos have to undergo a railway journey it is advisable to gather them before they are fully ripe, as in that state they would reach their destination in better condition. It should, however, be remembered that probably there is no fruit that deteriorates more quickly than the tomato after it is removed from the plant. It is owing to this fact that home-grown tomatos are so incomparably better than those imported. When tomatos have attained their full size, and are cut off in a green state, they will subsequently assume an appearance of ripening, but there can be no comparison between such fruit and that which is ripened on the plant.

NEW PLANTS, FLOWERS, AND VEGETABLES.

LÆLIO-CATTLEYA HIPPOLYTA DULCOTE VAR.

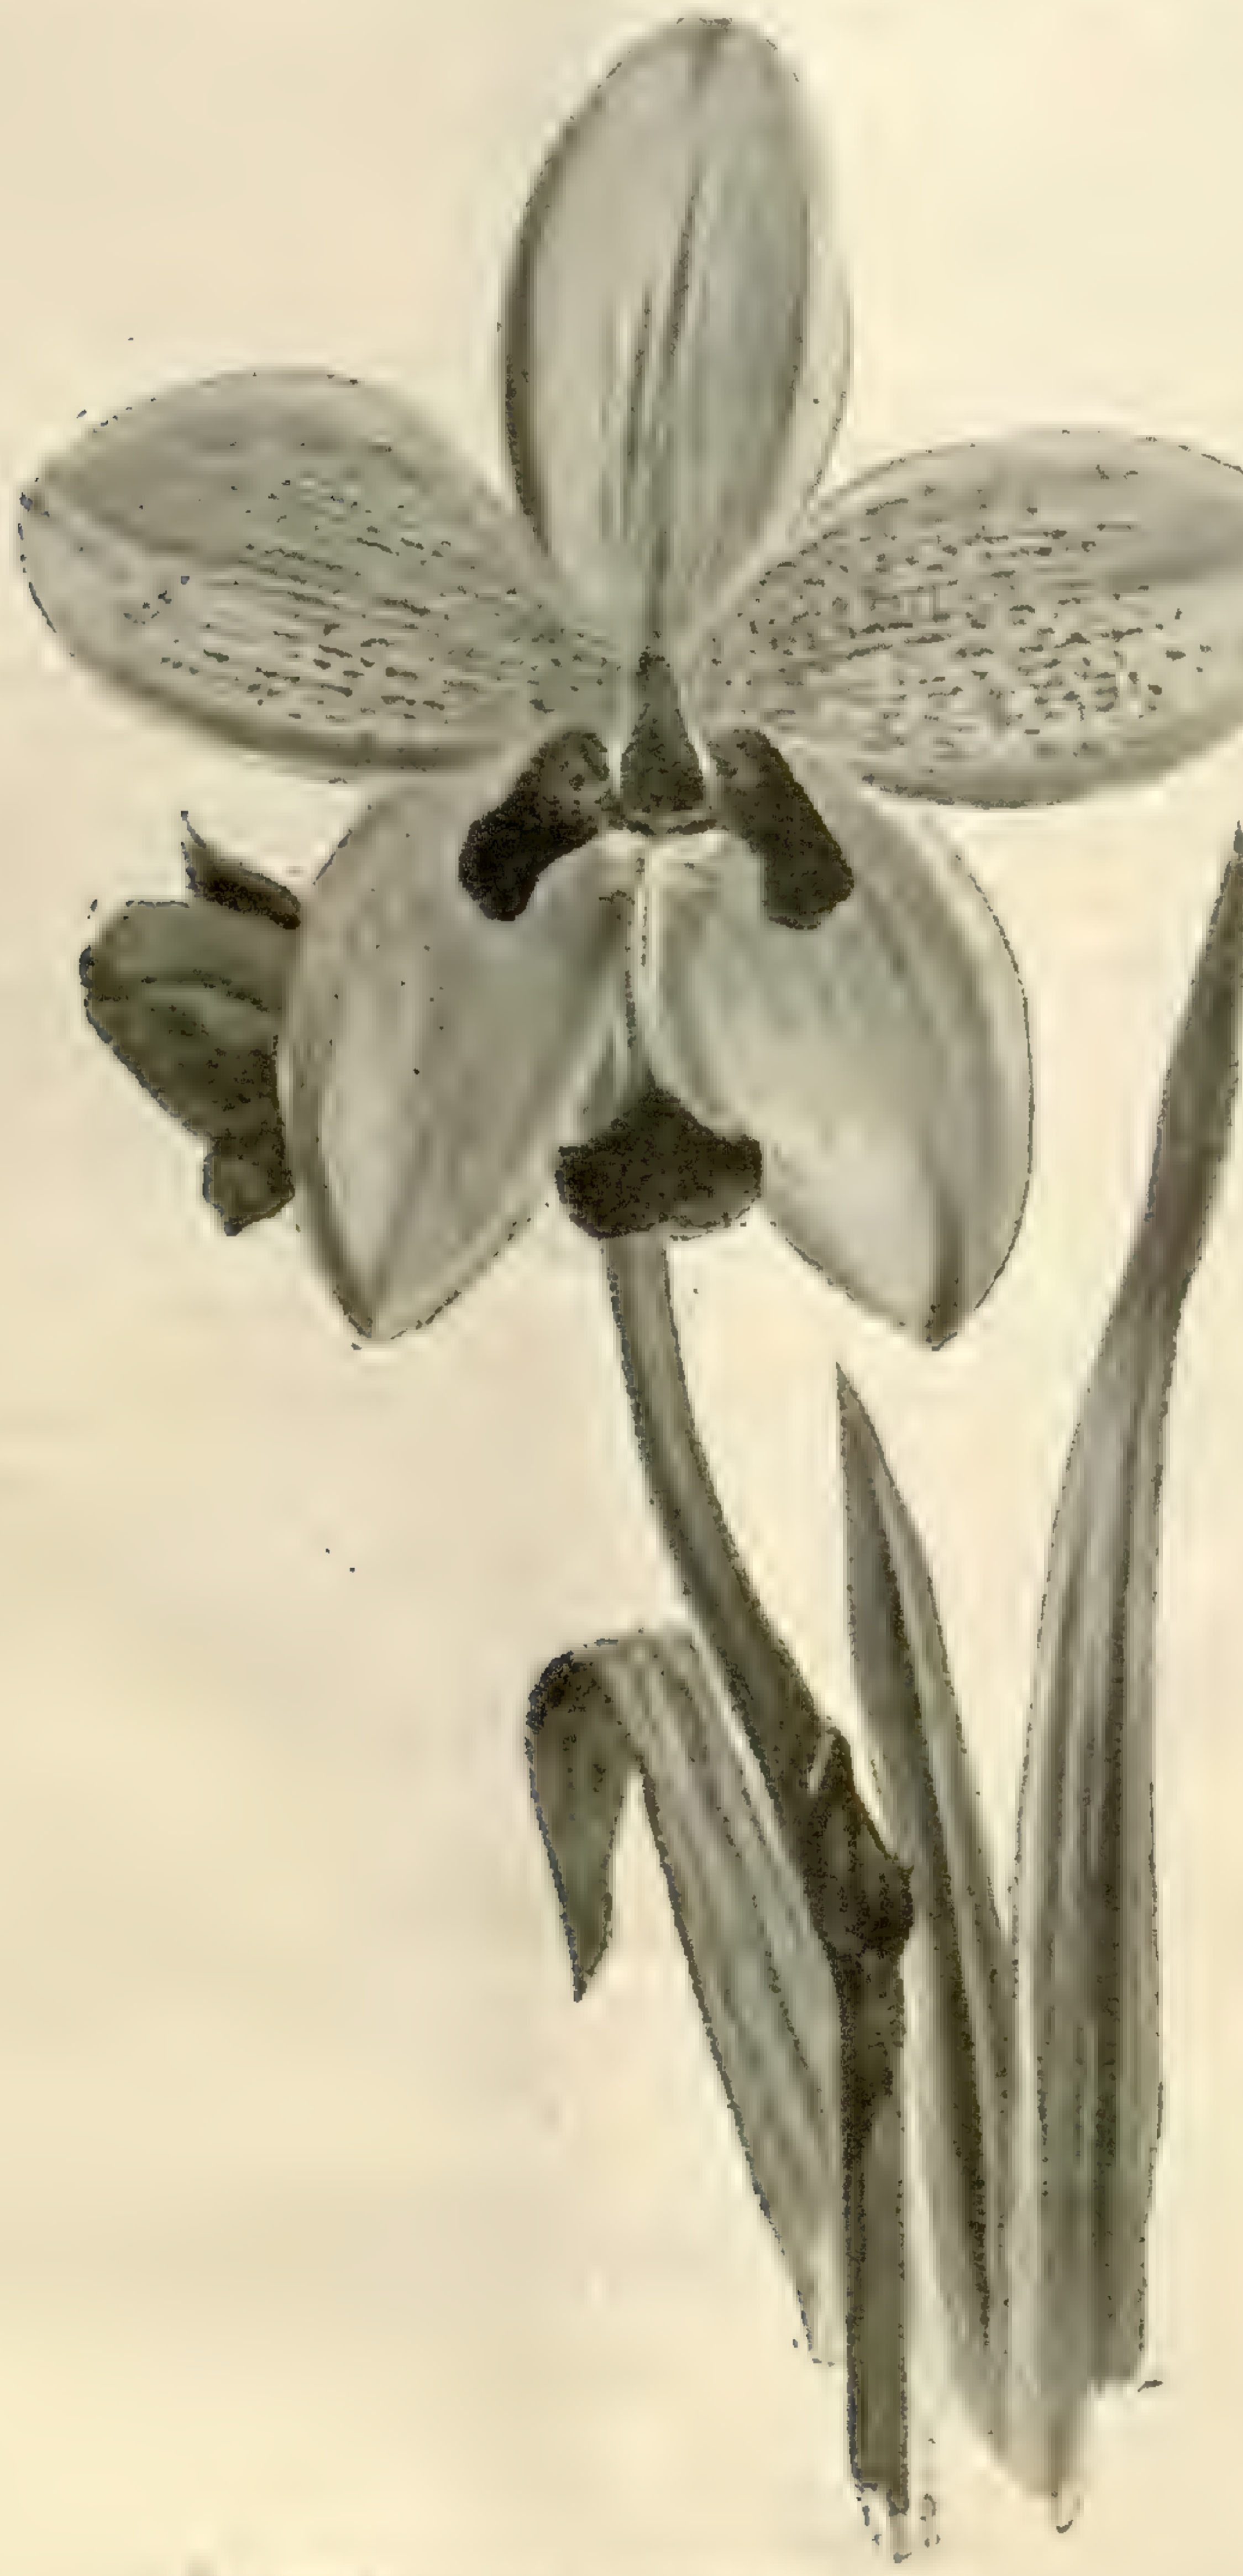
AN extremely handsome form of a hybrid orchid now comparatively well-known among orchidists. It differs from the type in having handsome flowers of an exquisite orange shade with tinges of scarlet, or rather, cinnabar-red, towards the margins of the sepals and petals. The long and somewhat narrow lip is of a curious shade of rosy crimson, and is wonderfully waved and crisped. The plant shown bore five splendid flowers. F.C.C., R.H.S., May 10. Walter Cobb, Esq., Dulcote, Tunbridge Wells.

LÆLIO-CATTLEYA FASCINATOR.

A bold and handsome hybrid with soft rose-purple sepals and petals, and a huge bright purple lip having a yellow throat. The sepals are very narrow, but the petals very broad, though with reflexed margins. The lip has a white tube, but a clear and soft yellow throat; the apex is rounded, large, broad, and frilled, deep and rich purple with pale margin. Obtained by crossing Lælia purpurata with Cattleya Schröderæ. F.C.C., R.H.S., May 10. Mr. Bond, gardener to C. L. N. Ingram, Esq., Godalming.

SPATHOGLOTTIS AUREO-VIEILLARDI.

A beautiful orchid and one of great interest, for it is a hybrid between the two species indicated by the name. The foliage is long and plicate, pale green; flowers two and three quarter inches across, sepals somewhat narrower than the petals, and of a soft primrose tint with faint rose tips. The broad, rounded petals are of a similar colour but plentifully strewn, save at the tips, with very tiny rose-purple dots. The lip has crimson side lobes edged with yellow and cream at their bases; front lobe yellow along the neck and two raised teeth, but with a rich rosy crimson wedge-shaped apex. F.C.C., R.H.S., May 10. Messrs. J. Veitch and Sons, Chelsea.



SPATHOGLOTTIS AUREO-VIEILLARDI.

SOPHRO-CATTLEYA GEORGE HARDY.

A very distinct and interesting hybrid obtained by crossing Sophronitis grandiflora and Cattleya Acklandiæ. The plant has growths about three inches high, surmounted by leaves of a similar length. The flower shown measured precisely two inches across, and had equal sepals and petals, all rounded at the apex. The colour was soft scarlet, with red spots at the tips of the segments. Lip tiny, scarlet with orange base. A.M., R.H.S., May 10. Mr. T. Stafford, gardener to F. Hardy, Esq., Tyntesfield, Ashton-on-Mersey.

CATTLEYA INTERMEDIA FOWLER'S VAR.

A pretty orchid, with growth and spikes like those of Lælio-cattleya elegans. The flowers measure four to five inches across; sepals and petals half-an-inch across, tinged palest lilac; lip large, lilac tube, creamy throat, and tips of the side lobes of a similar colour; front lobe much waved and crisped and of a rich royal purple hue, this colour extending up the centre of the throat of the lip. A.M., R.H.S., May 10. Mr. J. Davis, gardener to J. Gurney Fowler, Esq., Glebelands, South Woodford.

AZALEAS.

Madame Joseph Vervaene, a handsome semi-double Indian azalea, with large flowers of a lovely pink shade, and with numerous bright rose-red spots upon the upper segments. A.M., R.H.S., May 10. F.C., R.B.S., May 11. Mr. Charles Turner, Slough.

Ami Charles Vermeire, a fine single Indian azalea, with an abundance [illegible] and intense scarlet flowers, with a few crimson spots at the base of the [illegible] segments. A.M., R.H.S., May 10. F.C., R.B.S., May 11. Mr. Charles Turner, Slough.

La Printemps, single, rich scarlet with deep crimson-scarlet spots on the [illegible] of the three upper segments.

Ami Victor Cuvelier, a handsome pink azalea with semi-double flowers; [illegible] upper segments are stained and spotted with crimson-scarlet at the base.

Louise Cuvelier, a pretty semi-double variety; pure white and very [illegible] flowers large. F.C. to each, R.B.S., May 11. Mr. Charles Turner, [illegible] Nurseries, Slough.

AURICULAS.

Perfection, a grand alpine auricula with bold trusses of handsome large [illegible] a lovely intense crimson shade and with a beautiful golden centre.

Zixa, a pretty alpine form with blackish-crimson shading at the base [illegible] blood-red segments; centre deep yellow.

Dean Hole, a beautiful alpine auricula with rich crimson flowers, tinged [illegible] deeper shade at the bases of the segments, and with a golden centre. A.M., R.H.S., to each May 10. Mr. J. Douglas, Great Bookham, Surrey.

DRACÆNA ROSE LAING.

A handsome and graceful dracæna, with leaves twelve to fifteen inches long by three inches across at their widest; deep purplish-green, with scarlet streaks on the older leaves; young foliage creamy, with green and red shadings. A very good dracæna. B.C., R.B.S., May 11. Messrs. J. Laing and Sons, Forest Hill.

TULIPS.

Glow, a scarlet Darwin tulip, shaded with vermilion; very neat in appearance, effective *en masse*, and looking well when cut.

Salmon King, a pretty Darwin tulip, with neat flowers of a peculiar shade of rosy scarlet that has not a very near approach to salmon. F.C. to each, R.B.S., May 11. Messrs. Barr and Sons, Covent Garden.

ADONIS PYRENAICA.

A handsome adonis with large golden flowers and finely-divided foliage; a good garden plant and one fairly well known. B.C., R.B.S., May 11. Messrs. Barr and Sons, Covent Garden.

CHEIRANTHUS HARPUR CREWE.

A very much branched and dwarf-growing wallflower, with small spikes of double-yellow flowers. The foliage is small, and the whole plant is very handsome. Flowers sweetly fragrant. B.C., R.B.S., May 11. Messrs. Barr and Sons.

BEGONIA EARL OF DARTMOUTH.

A splendid soft salmon-scarlet double tuberous begonia, of handsome form and neat appearance. F.C., R.B.S., May 11. Messrs. J. Laing and Sons, Forest Hill.

CALADIUM GUARALINGNETOR.

A bold foliaged form with fine crimson-scarlet leafage; towards the tips and margins the colour is bronzy, or deeper darker crimson. B.C., R.B.S., May 11. Messrs. J. Laing and Sons, Forest Hill.

RADISHES.

Barr's First of All Scarlet, an early olive-shaped radish of medium size, firm in flesh, and of a scarlet hue.

Barr's First of All White, rather larger than the foregoing, but otherwise similar in all but colour; pure white. A.M., R.H.S., to each, May 10. Messrs. Barr and Sons, Covent Garden.

Sutton's Forcing Carmine Olive, a useful early radish of good shape, dull scarlet in colour, and firm in flesh.

Sutton's Forcing White Olive is like the foregoing in all but colour; it is quite white, and equally early. A.M, R.H.S., May 10, to each. Messrs. Sutton and Sons, Reading.

Wood's Frame, a good old variety that still proves to be one of the best for early use; it has long red roots that are very crisp and well-flavoured. A.M., R.H.S., May 10. Messrs. Watkins and Simpson, Exeter Street, Strand.

NON-WARRANTY OF SEEDS.

THE case of Howcroft *v.* Laycock, and especially the resulting decision, is one of no small importance to all growers of plants from seed, as it practically gives the seedsman a right to sell any seed he likes under any description he chooses to attach, while absolving him from all responsibility as regards [illegible] That a seedsman should protect himself by a non-guarantee clause [illegible] extent of resulting crop, or even total failure, is justifiable enough, since [illegible] an immense amount of seed of good quality falls into unskilful hands, and hence, [illegible] a thousand and one causes, fails more or less to yield a proper crop; [illegible] quite another matter when a good crop, as regards quantity, being raised, [illegible] found to be of another and different plant to that of which seed was [illegible] invoiced. In the particular case in question, it is true that the difference [illegible] only that existing between two varieties of cabbage, but that difference was [illegible] theless sufficient to cause the defendant, who refused to pay for the seed, [illegible] his labour, use of his land, and the profits he might have made on the [illegible] intended to raise. It does not seem to have been at all disputed that the [illegible] obtained resulted from the seed supplied and sued for, or that it was essentially different from that which should have resulted; and yet it is held not [illegible] the seedsman is entitled to his claim for the value of the seed, but the [illegible] grower is nonsuited in his counterclaim for damages, and saddled with [illegible] costs owing to the seedsman's mistake. Surely no non-guarantee clause [illegible] world can over-ride equity to this extent, for, such a principle admitted, [illegible] immunity from damages and legal rights to the price charged, would [illegible] substitution of different plants altogether if the seeds were similar [illegible] appearance to elude the buyer's vigilance, and reach the stage of germination, [illegible] which time it is possible, or probable even, that the time for replacing the [illegible] article by the right one would be passed, and a season's crop be thereby [illegible] lost to the grower.

On the facts as presented, we certainly do not think the question should [illegible] where it is, though we fully appreciate that the glorious uncertainty of the [illegible] already exemplified in the first decision, renders the trouble and cost of an [illegible] a heavy and onerous matter for a private individual to undertake.

Recent Fire at Messrs. Watkins and Simpson's Establishment. —We are informed that Messrs. Watkins and Simpson have made [illegible] whereby their business is being carried on without interference or [illegible] Mercer Avenue, Neal Street, W.C.

SEAKALE IN THE OPEN GROUND.

Of late years the culture of seakale has made great advances, until now excellent produce can be obtained in one year from the root cuttings. There is no need, either, to force seakale if the supply is needed during the latter part of April and for early May. The old method of growing seakale for many years together in one place, covering it with pots and warm manures, is nearly obsolete, and the modern system is certainly a step in the right direction, as much better produce can be obtained at a smaller cost of labour. Those interested in open-air seakale culture evinced much interest in the fine groups of heads staged from Stoneleigh Abbey at the last meeting of the R.H.S.

At Syon we need seakale in large quantities, and so raise some thousands of plants yearly. It is a simple matter to grow seakale every year from root cuttings, and then produce may be had from November to to the middle of May, probably even later in the month. It has been stated that good seakale may be grown on poor land; I am aware that on the sea coast it grows year after year with little trouble taken to blanch the tops, the sea sand being drawn well over the plant; but these growths cannot compare with that produced on well-manured land. I am aware seakale is not at all fastidious as to soil, for, given ample moisture, it thrives. On the other hand, it thoroughly repays good culture, that is, annual culture, for, given good soil and ample food, the plants in one season will give crowns large enough for all purposes, and vastly better than the old much-divided root with numerous crowns, which cannot compete with plants giving a single crown and grown from one root cutting. There are other advantages with the one-year system; for instance, the crop will not occupy the quarter more than eight months, as it does the crowns good to lift them as soon as leaf-growth decays, if they are needed for forcing. Many think seakale cannot be grown without salt, but this is a mistake.

My note, however, is more concerned with the crowns that give the latest supplies, those we are now relying upon; and such may be grown by everyone who can give the necessary space, and with much less labour than many other vegetables. Once planted, one has merely to keep the quarter clean, and reduce the crown growth to one, and that the strongest; where liquid manure can be spared give copious supplies. We double dig or trench our land in the winter, placing a liberal quantity of decayed manure under the first spit; the position is an open one, as by full exposure a sturdier growth is secured. The planting is done early in April, and we rely upon root cuttings, prepared in the usual way when lifting; these are tied in bundles of fifty and placed in soil till needed for planting. The sets, as they are termed, may be hastened if placed in fine soil in frames, as treated thus they soon form roots at the base, and the crowns are early furnished with a number of small buds, but all these except one must be removed. When planting it is best to place the sets lower than the surface of the soil, as they have a tendency to lift themselves out of the ground as they increase in size. I have not referred to another and an excellent mode of culture, and that is to utilise any small roots of the previous year's growth which were not strong enough to force; these, cut over, will make excellent plants, but they must be cut, otherwise the crown growth will produce a flower. The distance to plant depends upon the space at command; but if the roots are lifted and forced, two feet will suffice between the rows, and fifteen inches between the plants in the rows. We plant two feet by eighteen inches, but lift every other row for forcing in a dark place.

In January or February, according to the season, we cover the plants left at four feet apart between the rows, first covering the crowns with fine [illegible] ashes before banking up the soil; indeed the ashes are a protection, and if placed over the crowns in December so much the better. We bank up the earth at the date named, ridge shape, quite two feet in height, and nearly as wide, for unless there is plenty of soil the tops soon push through. The plants may be grown in this way for two or three years, as not being forced they remain strong, but after the second year the crowns decrease in size and split up. Probably the least trouble is to lift all roots in winter, placing them close together under a north wall if late supplies are needed, and covering them with soil and litter.

Syon Gardens.

G. WYTHES.

Window Boxes.—There is one feature about these objects of domestic culture that merits special notice. It is that they do not, when on sills look-[illegible] the highway, exist solely for the pleasure of the owners. They are as [illegible] to every passer-by who loves flowers, and who does not? A prettily-[illegible] front window, and where there is a pretty front garden also, furnishes much charm to the house and beauty to the locality. Wherever we are privileged to see flowers growing in windows, within or without, or in the forecourts, conclusive evidence is furnished that amongst the inhabitants within reigns a high range of [illegible] and refinement. Whether flowers be or be not refining and humanising, [illegible] certainly they are evidence of the existence of better human nature than com-[illegible] prevails where flowers are not. Window boxes are elements of floral [illegible] not at all difficult to obtain. Wood is, on the whole, the best material, and can easily be made to exactly fit the window-sills on which they are to stand, whilst plain, if substantial, at the back and ends, they may be moderately [illegible] with moulding or lattice work in the front; but as the object of the planter should be to drape the front with plant growth as far as possible, the nature of the box face is of little moment. For hardy plants few thing are more in [illegible] to drape the front than creeping jenny or periwinkles, or some of the [illegible] leaved ivies may be utilised, and for tender plants free-growing lobelias, [illegible], musks, especially campanulas isophylla and fragilis, and ivy-leaved [illegible], are all first-class plants for such purpose. As to how the boxes [illegible] filled, the season of the year and the range of material at disposal should determine. In the winter a few small conifers or shrubs, some spring blooming plants, a few bulbs, anything indeed that will give leaf effect all the winter and bloom and beauty in the spring. As to the summer, there is endless variety, but in all cases too much variety and colour should be avoided.—A. D.

EXHIBITION CHRYSANTHEMUMS.

THE number of shoots which plants may develop to carry large flowers for show purposes is governed by the particular variety or by the condition of the plant. For many years it has been the custom to leave three shoots to each plant, but there are reasons why this is not always good practice. Strong-growing varieties and those which are apt to give blooms of an ungainly character may occasionally have four shoots, providing these can be induced to grow evenly. The greater part of the collection will carry three shoots if rooted in good time and grown well, but some varieties which are naturally weakly will give better blooms if restricted to two shoots; there are also a few which never start three growths uniformly, and consequently the lowermost of the three selected does not become vigorous enough to give a good flower. Now, if this sort is especially liable to damping of the blooms, the lower or weakest shoot may be allowed to remain to prevent the too vigorous growth of the two leaders, but if the contrary, then the weakest shoot may be pinched away at its first appearance, as by this the two best shoots retained will be proportionately more robust. Those plants which are pinched in order to time the flower buds are most likely to have their topmost one or two shoots grow at the expense of the lower one, but this uneven growth is peculiar to a few varieties. Those which are rooted late in the season may, according to the time of propagation and the vigour of the plant, be allowed one, two, or three shoots. Frequently new varieties are not strong enough the first year, through their being subjected to rapid propagation, to carry three blooms successfully, hence it may be sometimes well to confine the energies of the plant to one growth only for the chance of a good bloom, rather than try more. The finest bloom of Oceana I have seen was grown in this way on a late plant by Mr. Beckett, of Aldenham Gardens—just the one bloom on the plant. Side shoots in excess of those required must be carefully removed as soon as they can be safely handled without breaking off the main leaf in the process. Some varieties are so very brittle in the leaf-stalk or at the axes of the leaves that the caution is necessary. Mrs. H. Weeks, Mutual Friend, and Mons. Panckoucke, for instance, are easily damaged.

Many varieties will have either made their natural break or have been pinched to induce the side shoots to grow away by this time. In spite of the mildness of the winter there does not appear to be any undue earliness of the break buds this season. Madame Carnot, Simplicity, M. Chenon de Leche, Mrs. Carpenter, Mrs. H. Kloss, and Western King, amongst others, were showing their buds by April 28, and the pots are becoming well occupied with roots. Where plants have been potted firmly as previously recommended, and in strong soil, watering is a particularly important matter; moisture cannot pass through the soil so freely as if the plants were potted more loosely and in lighter soil. Hence the repeated injunction to water thoroughly when necessary is a point which cannot be too strongly impressed on young growers, otherwise, if sufficient water is not given to moisten the whole ball of soil, the lower portion may become dry, and the roots will consequently suffer. There are some varieties which cannot bear the least excess of water during the early stages of their growth; Madame Carnot, Mrs. Lees, Mutual Friend, and Australie are examples; these soon show a pale, unhealthy colour in their foliage if over-watered, but if the advice to water carefully by examining each plant be followed, it will prevent injury from this cause. It is through indiscriminate attention that plants suffer, on the assumption that because many appear dry the whole batch may be watered, whereas it is possible for a plant of such a strong-growing kind as Eva Knowles to need water three times, whilst Mutual Friend will require it but once during the same time.

The experience of the last few years has been in favour of keeping the plants under protection until after the end of April. The lights of frames may be removed entirely, and when frost threatens or heavy rain seems imminent they may easily be replaced, and so secure the plants from injury. Often, however, one has no choice but to turn out chrysanthemums in order to give frame shelter to more tender plants at this time of year. When this is the case, a position sheltered from cold winds must be found for them, and provision made for a light covering to be run over on very cold nights. If the outside temperature is below 40 degrees by ten p.m. we generally expect and prepare for frost until after May 20 has passed. Stakes will be necessary for most of the plants when removed to the open, and, in tying, either support the shoot its whole length or leave some six inches or more loose, as the tender tops are apt to snap off some varieties under the influence of heavy rain or wind when tied stiffly to within about four inches of their points. No feeding should be necessary under ordinary circumstances whilst the plants are in six-inch pots. Manure may be given if, from force of circumstances, later on, when the plants are ready for their shift into large pots, the work cannot be done just as soon as required, but this only to prevent loss of vigour rather than to encourage strong growth. It is little use giving manures to weakly plants unless they have a goodly number of roots; a healthy root action would generally be better stimulated by slightly warmer and more moist surroundings, and then, perhaps, a little weak liquid manure might do good if the soil is not rich enough.

It may be well to advise caution in measuring the cubic capacity of frames with a view to fumigating. There is usually only such a small space, and one is apt to overlook the fact that the pots and plants occupy a large portion of this, so that it is easy to fumigate too strongly unless due allowances are made.

Trent Park Gardens.

W. H. LEES.

Seed Potatos for Ireland.—We understand that the Government has made arrangements for the distribution of thirty tons of seed potatos among the distressed Irish families in the Patrie Mountains. Relief works have been opened.

FRUIT BLOSSOM.

THE plum trees on the south and east walls have been a foam of white flowers, and when their glory waned the pear trees opened out great clusters of snowy blossoms, and the smaller, paler blooms of the cherry appeared. Last to come, but loveliest of all when it does arrive, is the apple blossom. The grey-brown of its gnarled stems and branches, the vivid green of its leaves, and the pink and white of the bloom, make an apple tree in flower one of the most beautiful colour schemes to be found in Nature.

It is doubtful whether any order of plants can show, with such a similarity of flower, such a diversity of fruit as can the order of Rosaceæ. For besides such well-known and conspicuous examples as the rose, hawthorn, sloe, plum, cherry, almond, peach, apricot, apple, pear, medlar, quince, strawberry, raspberry, and bramble, there are the more insignificant but not less interesting fruits of the burnets, spiræas, geums, and potentillas. The flowers of all these, though differing greatly in size and colour, are very similar in general structure as far as the two most obvious organs, the corolla and stamens, are concerned. Their variations lie in the number of the pistils, and the curious relationships that exist between the pistil and the calyx, and it is to these that the differences of the fruits are to be ascribed.

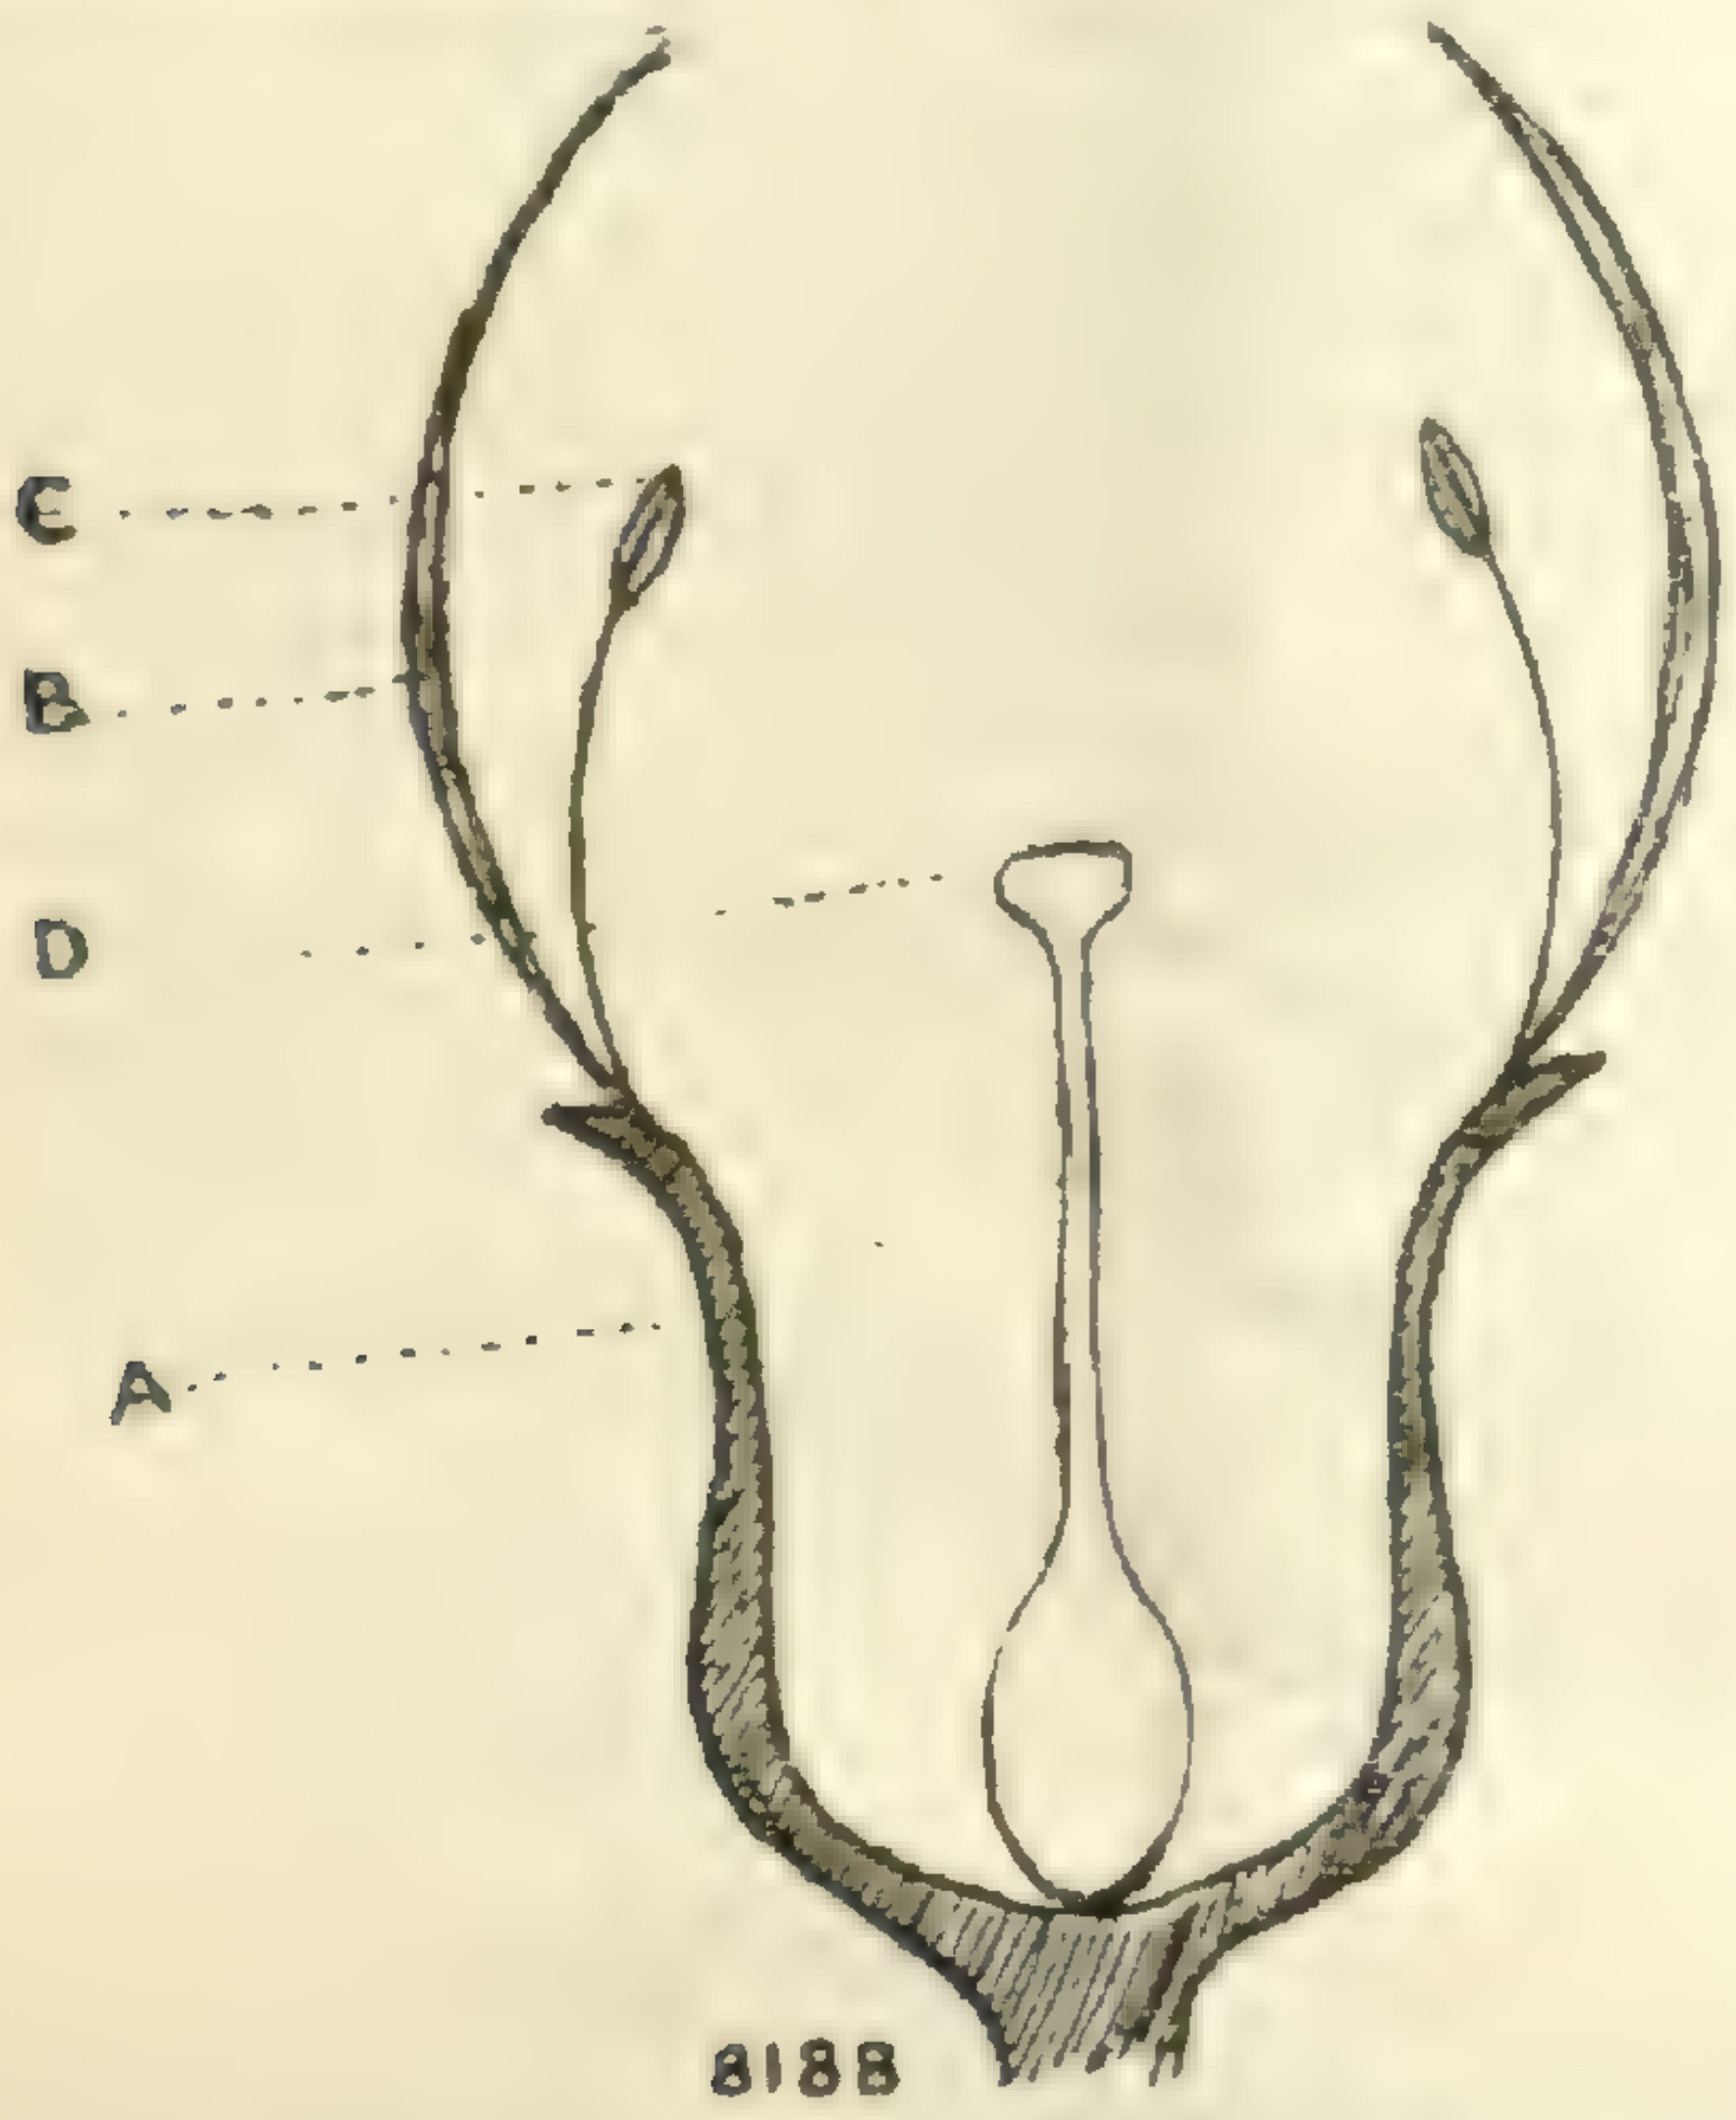


Diagram of Plum Blossom.

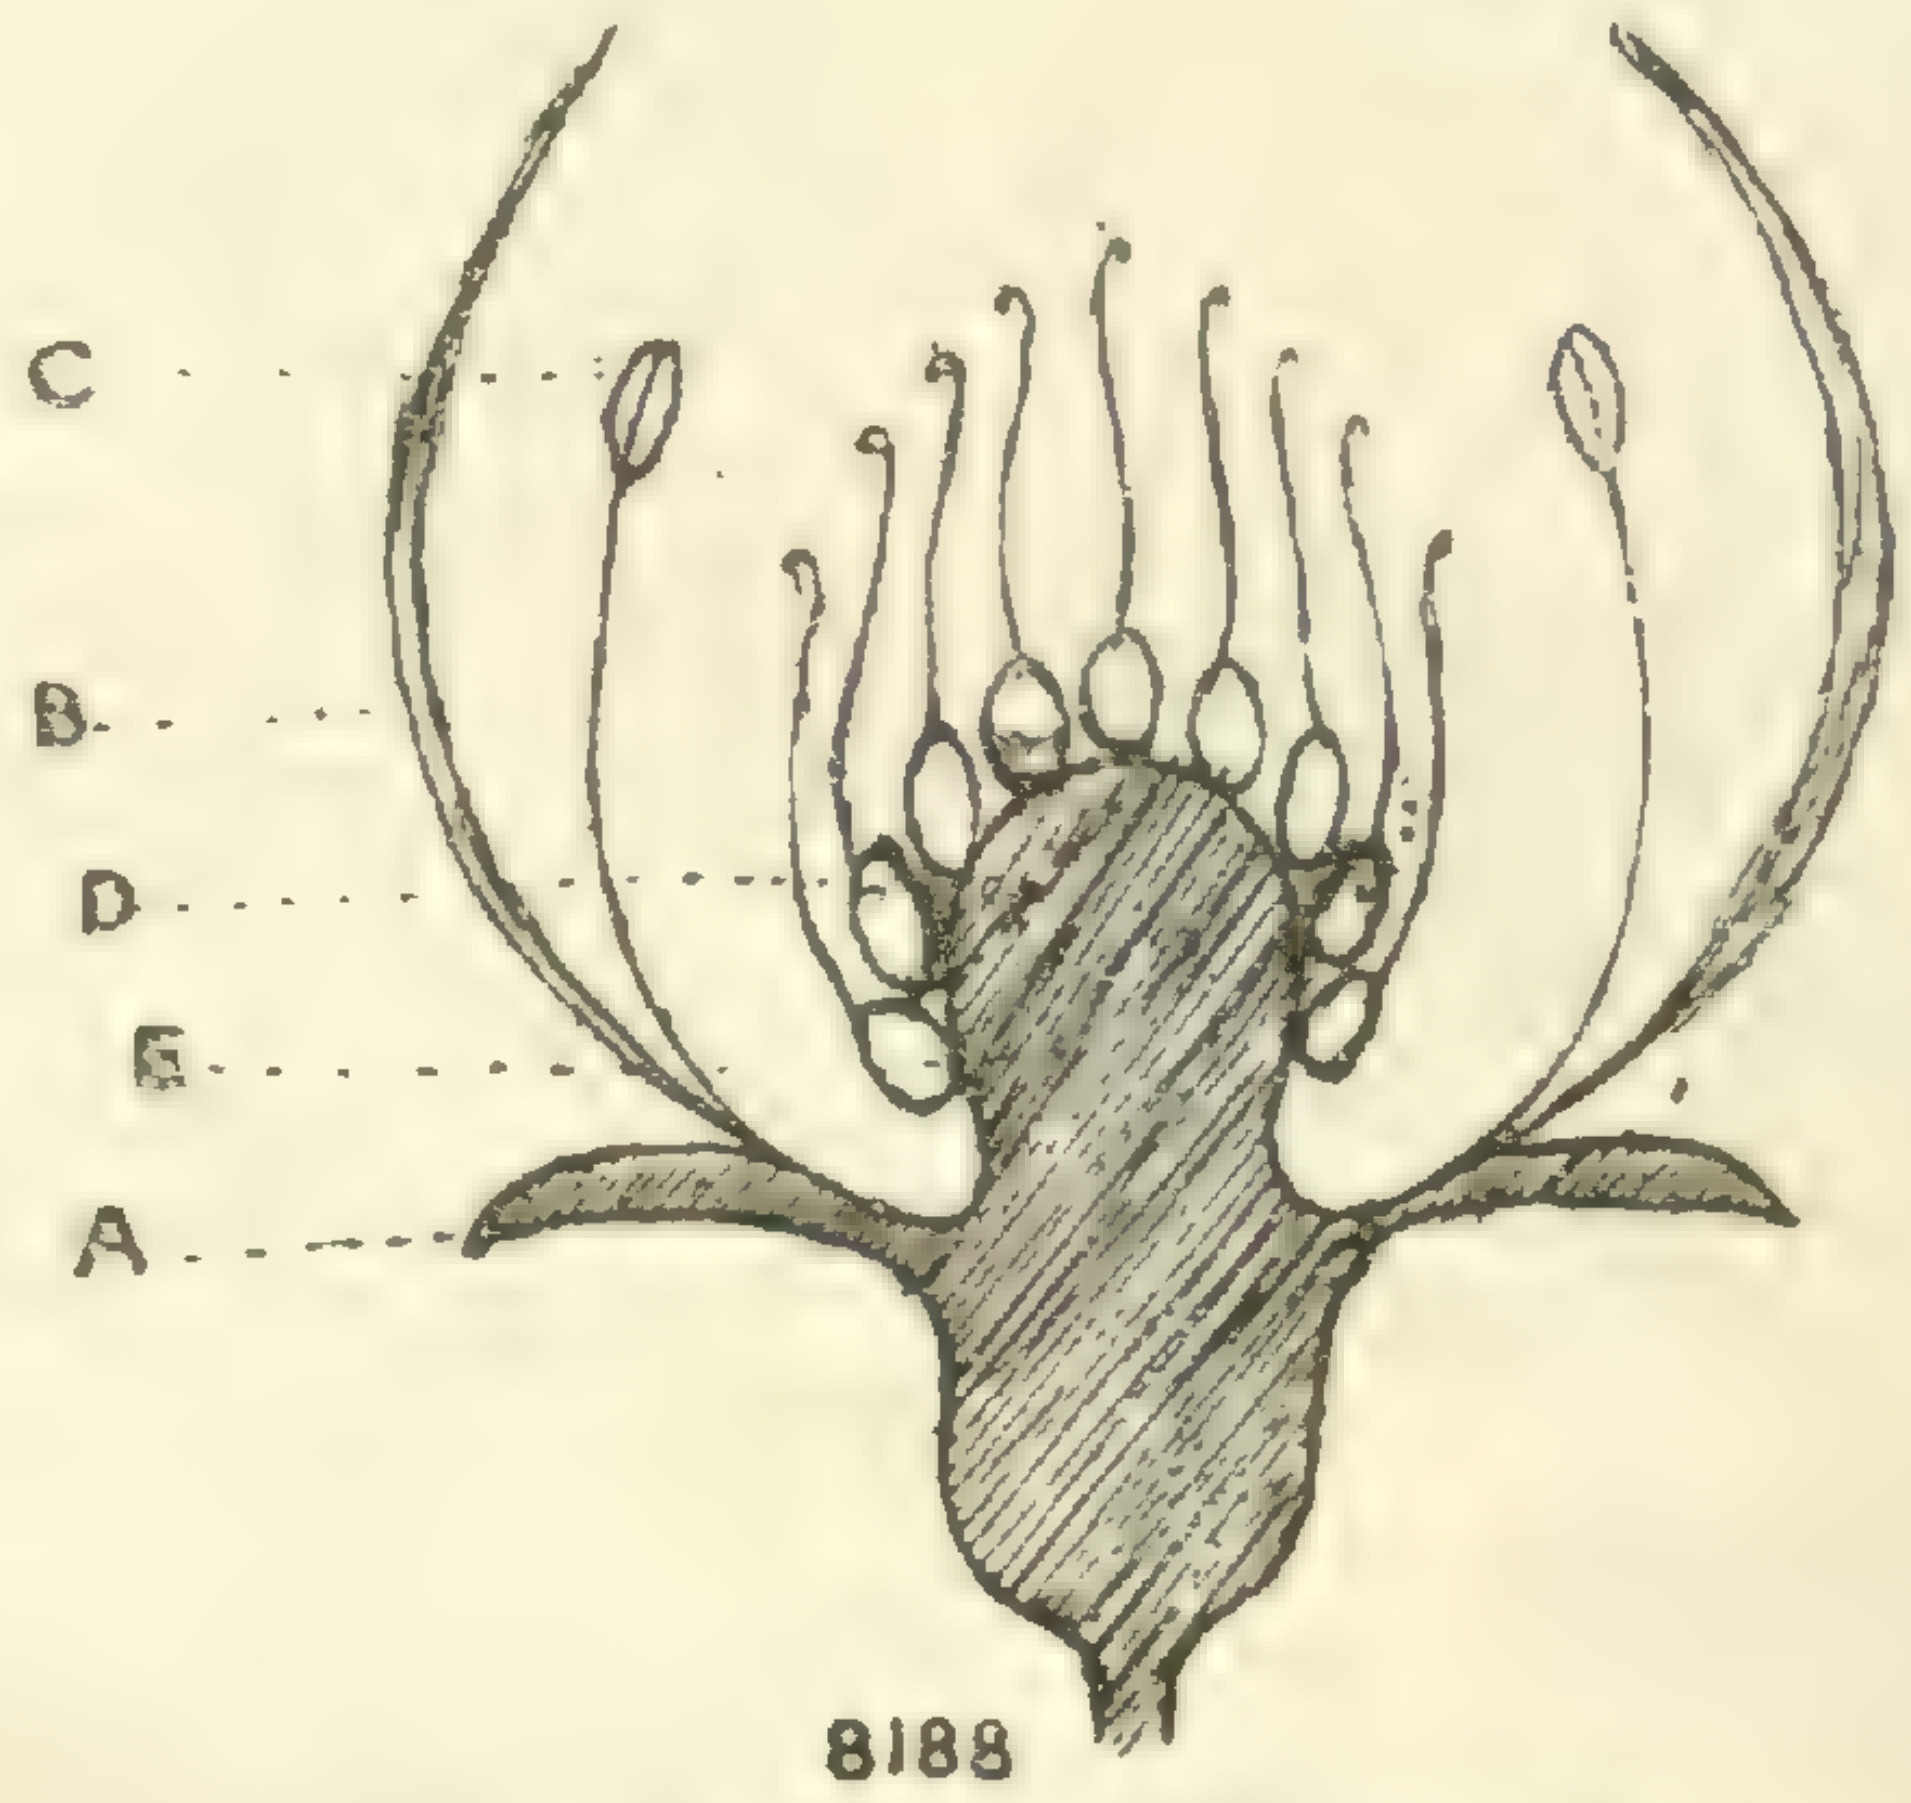

Diagram of Bramble Blossom.

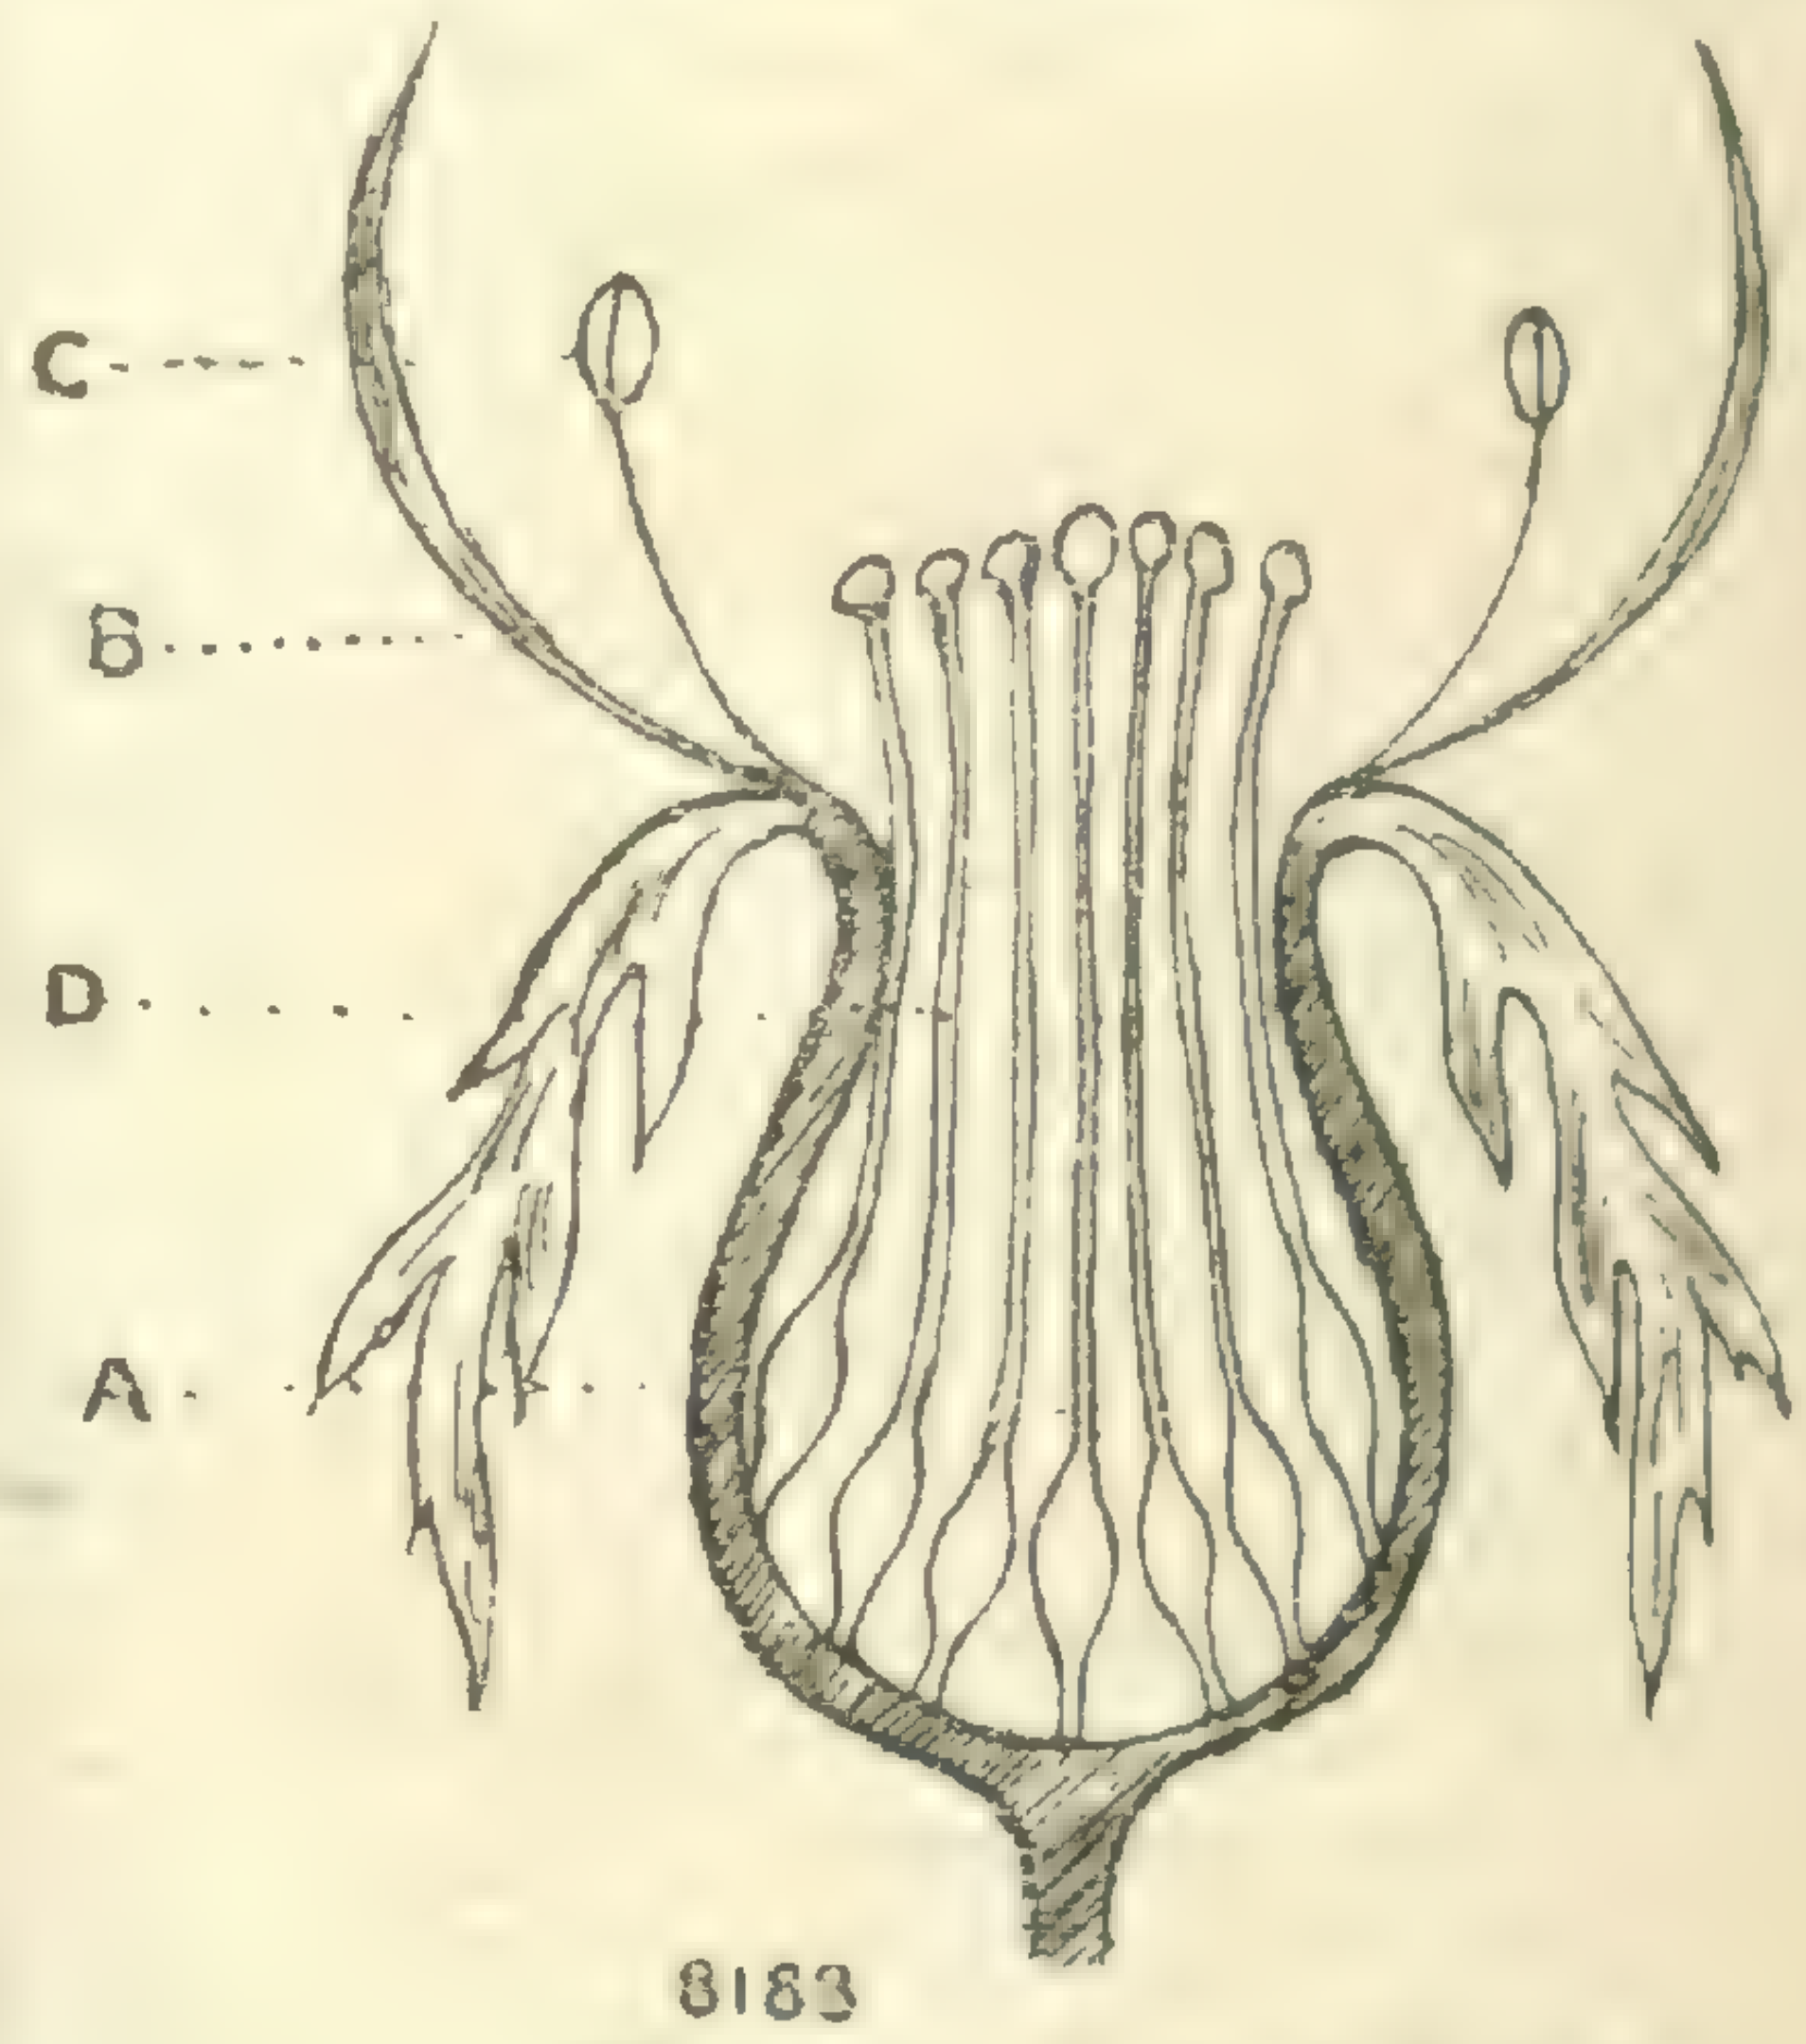

Diagram of Rose Blossom.

A, calyx ; B, corolla ; C, stamen ; D, pistil ; E, disc.

The accompanying diagrams show four of the more important of these variations. No. 1. is of the plum blossom. The calyx is in the form of a deep cup, in the middle of the base of which grows a solitary pistil. This, after fertilisation, develops into a plum, the calyx, corolla, and stamens dying away, and leaving only the fruit on the flower-stalk. The almond, peach, cherry, and nectarine are all formed in a similar way, and are all, technically speaking, drupes ; that is to say, fruits consisting of an outer succulent portion enclosing an inner, stony portion which contains the seed. No. 2 is of the raspberry blossom. The base of the calyx is filled with tissue which rises into the centre of the flower as a conical disc, and bears the pistils. These develop into little juicy drupelets, exactly similar in structure to the drupes, though so much smaller. It follows, then, that a raspberry, bramble, or dewberry is not a single fruit, but a collection of fruits. No. 3 is of the rose blossom. The calyx is tubular in form, and attached to its inner base and sides are many little flask-shaped pistils, the heads of which make the yellow-green centre of the flower. As the fertilised pistil ripens into the small, hard, stony fruit, the calyx-tube ripens with it, entirely enclosing the true fruit, and forming the scarlet hip which makes our hedgerows bright in autumn and which children not inaptly call "Soldiers' Buttons." No. 4 is of the apple blossom. The calyx is, again, cup-shaped, and inside, growing from its base, are two, three, four, or five pistils. After these have been fertilised, an extraordinary change takes place in the flower. The whole of the calyx-tube swells up and develops into a mass of soft edible tissue, which constitutes a false fruit, and encloses the true fruit as the core. Such fruits are called pomes, other kinds of which are the pear, medlar, and quince.

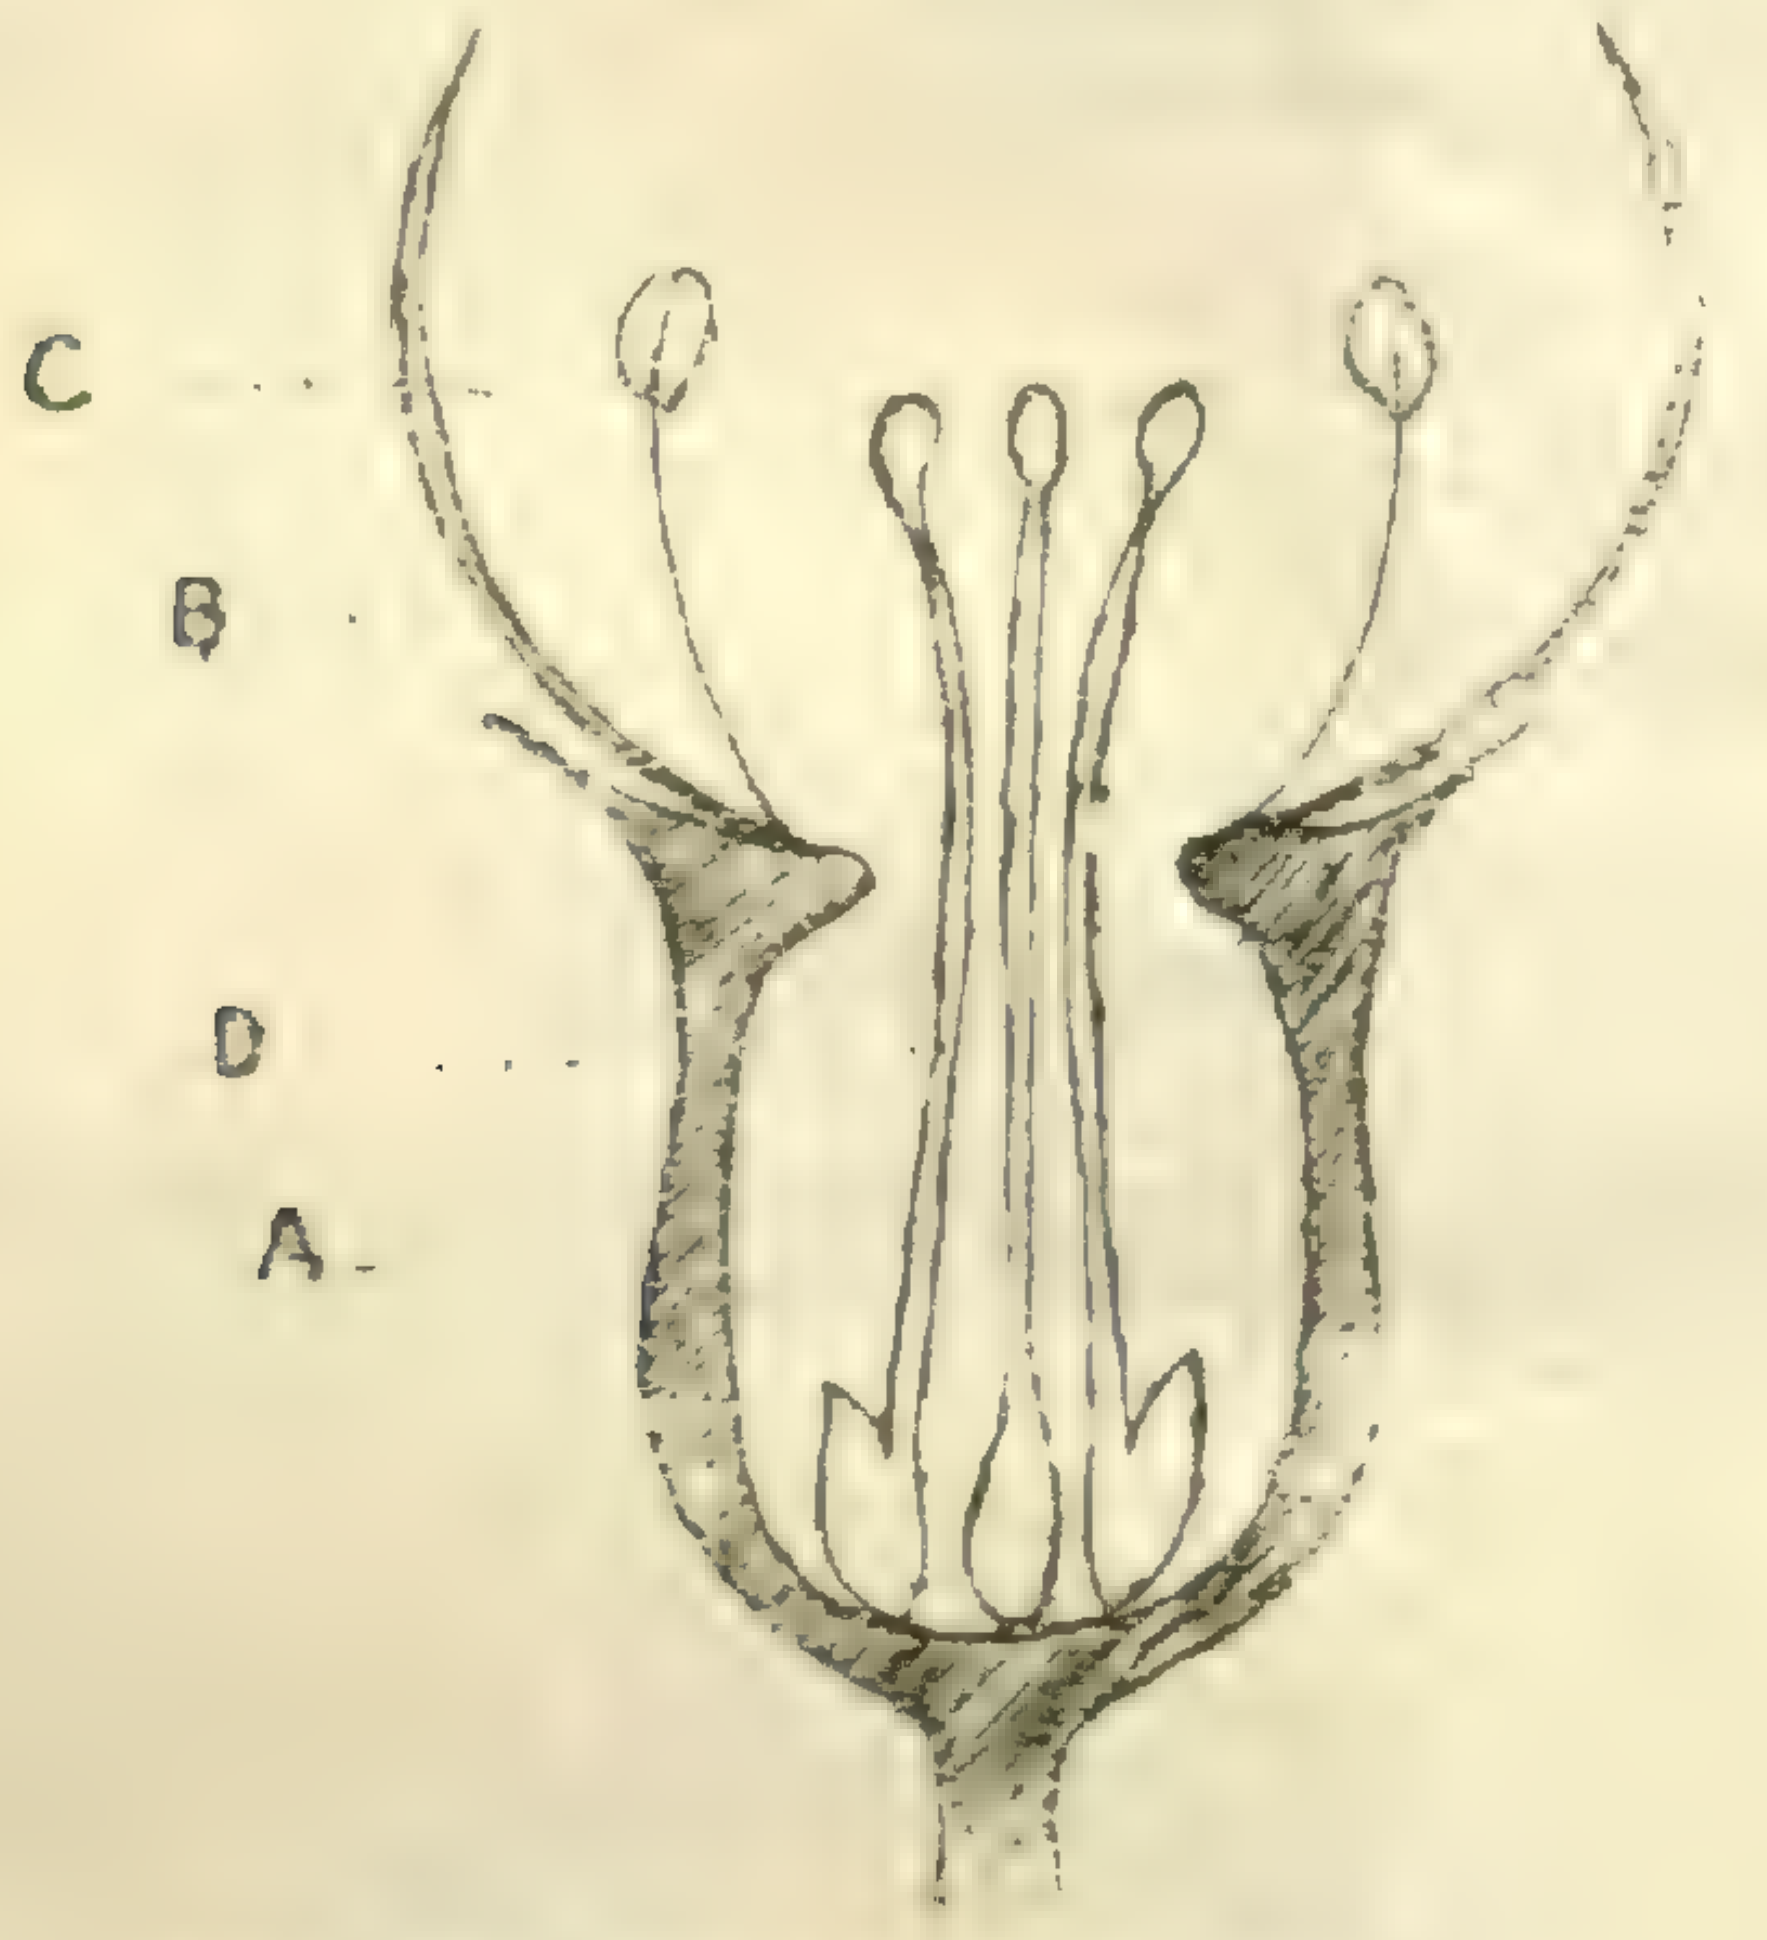

Diagram of Apple Blossom.

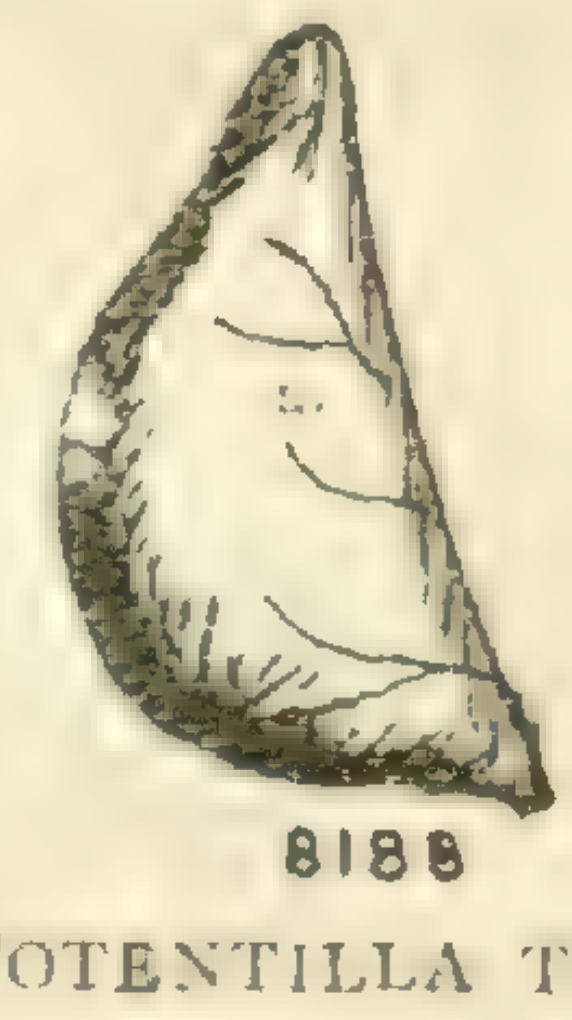
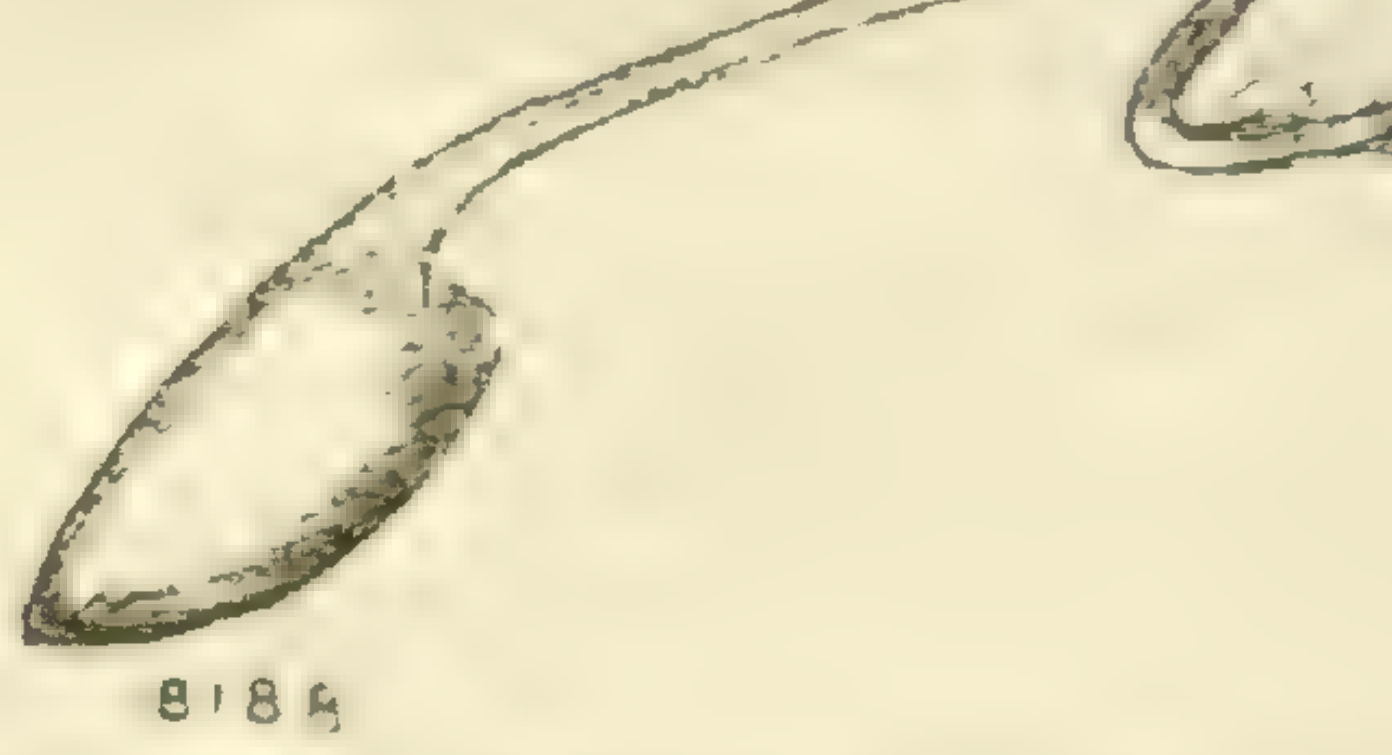
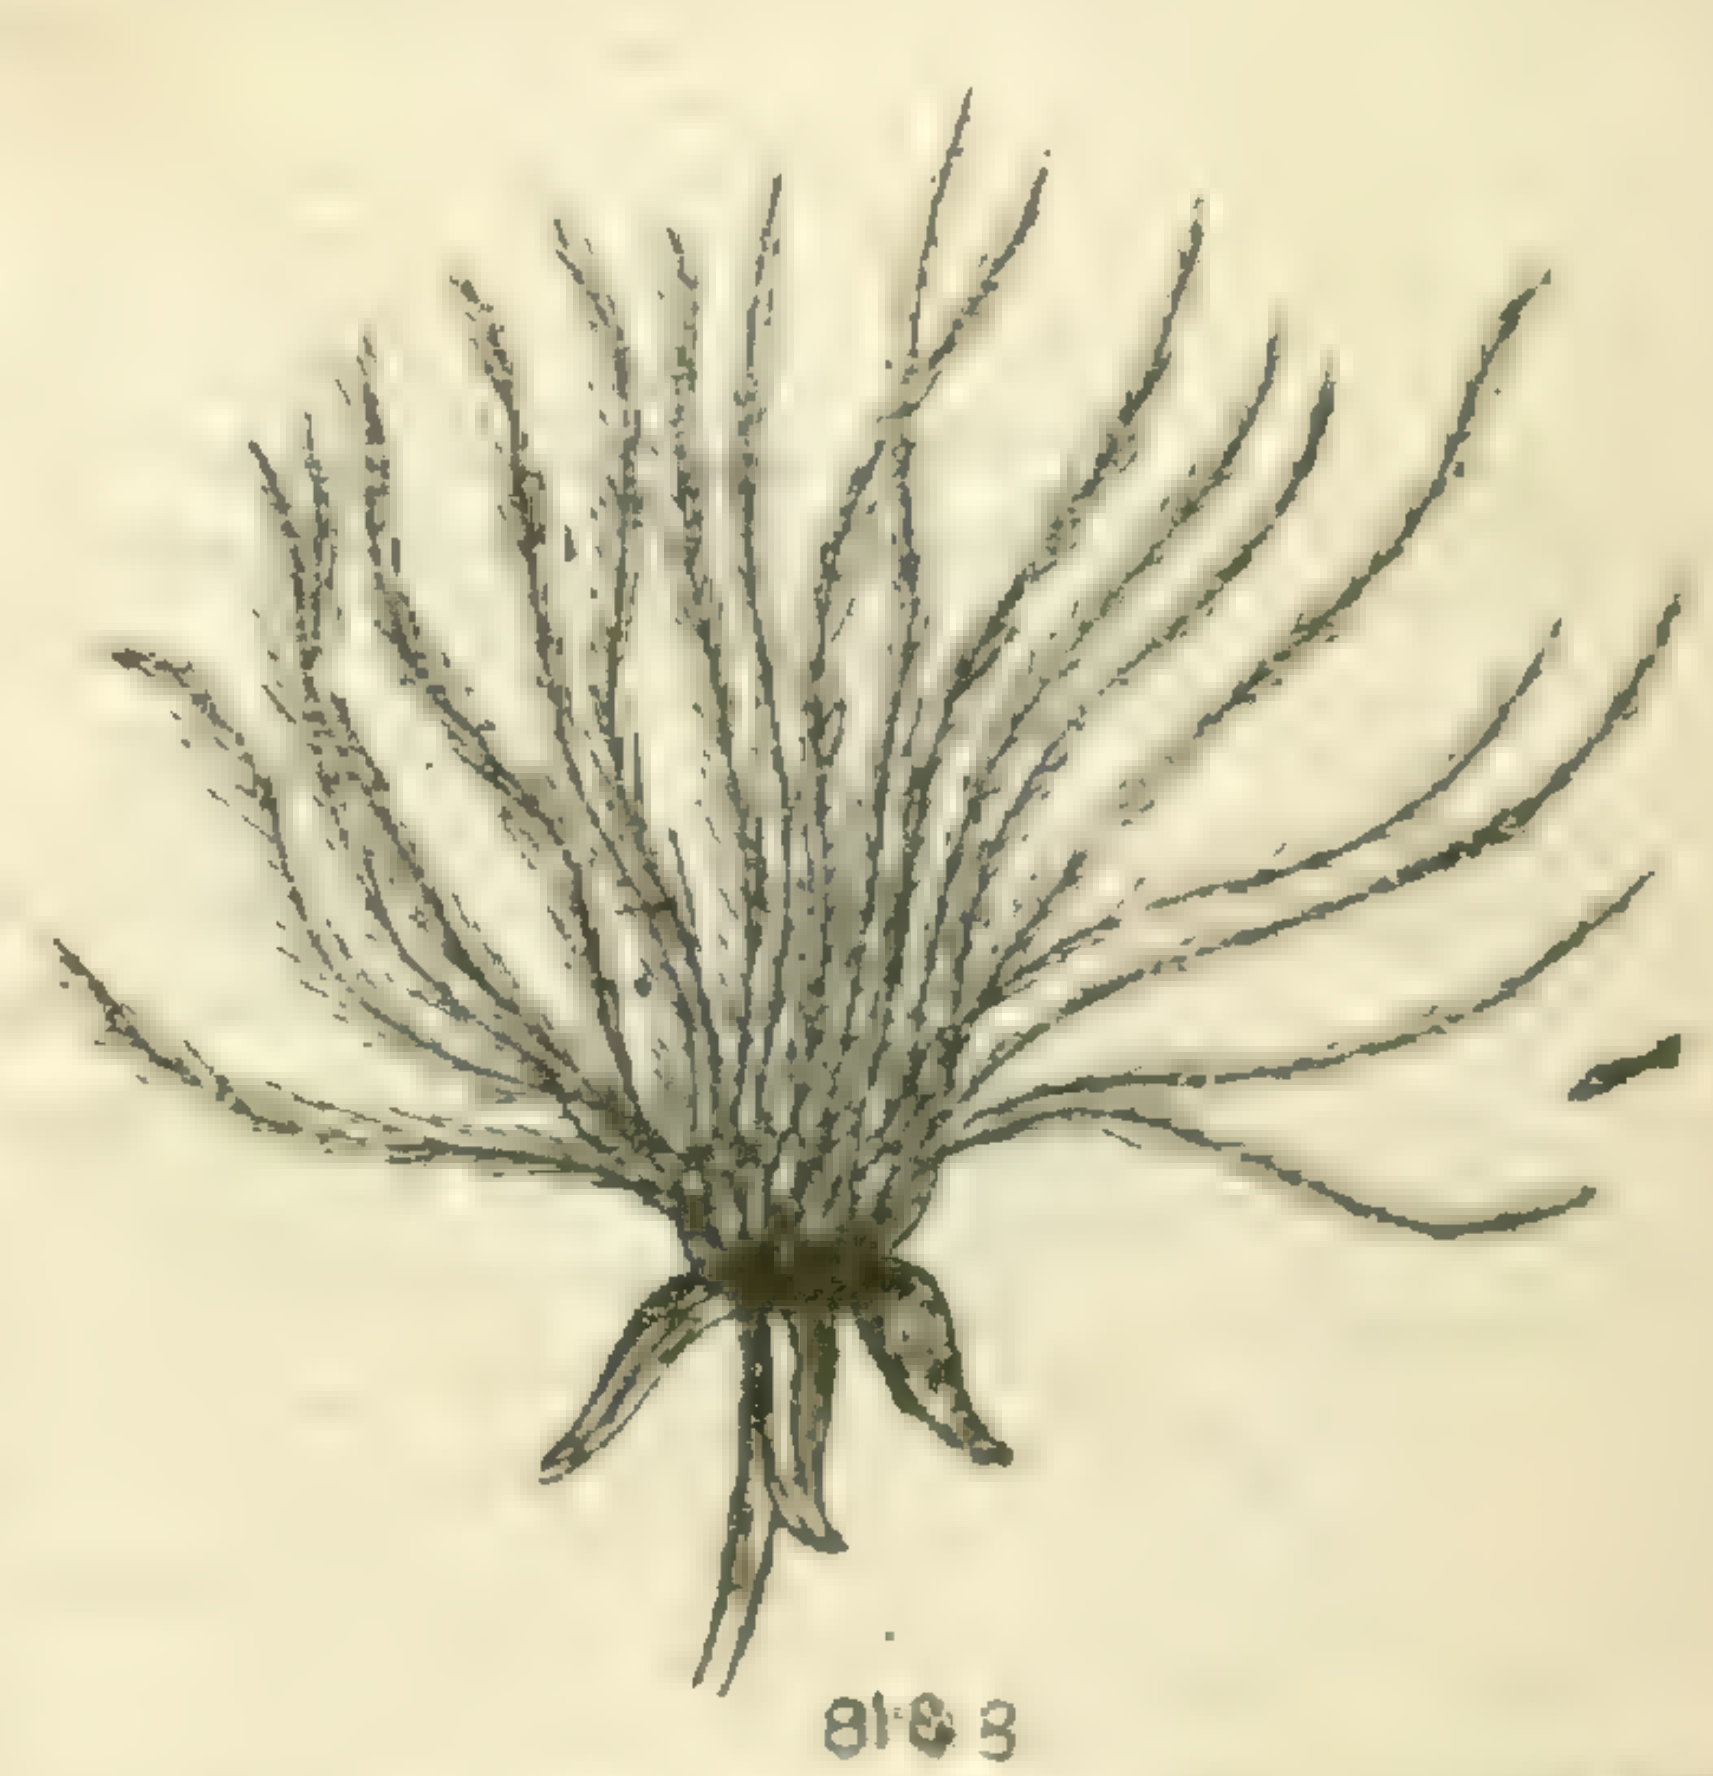


Fruit of Potentilla tormentilla.



Fruit of Wood Avens (*Geum urbanum*).



Fruit of Mountain Avens (*Dryas octopetala*).

The fruit of the strawberry is best understood by first examining that of the little yellow-flowered potentilla. This is of the simplest type, consisting of a number of seedlike bodies, technically known as achenes, each containing its seed fast closed in a dry covering. These achenes grow on a dry flattened disc. The fruits of the geums are similar, but they possess appendages which assist in their dissemination. The strawberry is a plant of the same habit as the potentilla, and has the same kind of fruit, but the disc instead of being flat and dry has become large, succulent, and fleshy, exquisite in colour, delicious in flavour, and bears the seed-like fruits embedded on its surface. No order presents more interesting evidences of the process of an evolution extending over many ages than does the rose order. The prototype of our highly developed and highly civilised orchard trees is the little creeping potentilla mentioned above—a humble little plant with yellow flowers and much divided simple leaves, primitive in habit as its colouring, if yellow be, as many hold it is, the primitive floral colour. Out of this, in course of time, evolved a plant known as the barren wild strawberry, placed by some authorities among the potentillas, by others among the fragarias or strawberries. The much-divided simple leaves were transformed to compound leaves with the leaflets, the yellow flowers became white, and the plant grew in tufts instead of in straggling runners. After another lapse of time, out of this came the strawberry, Fragaria vesca, a more erect plant with the same threefold leaves, but with larger, whiter flowers and the edible fruit that has been described. The birds liked the fruit, ate it, and thus dispersed the seeds more effectively than the wind or a chance agent, and the type became fixed and far-spread.

Next in order would come the spiræas and geums, taller herbs, with dry, insignificant-looking fruits, and after them the raspberry and bramble, larger and more imposing plants, with edible fruits, and long, woody stems, which, however, could not hold themselves erect, with fruits so liked by the birds that the dispersion of the seeds and the survival of the type was assured. The primitive rose not only produced an infinite variety of its own kind, which have been further multiplied, developed, and differentiated by culture, but it gave rise to three types distinct from it and from each other—the hawthorn, plum, and apple. In these we arrive at woodland trees which stand erect. The only obvious connecting link between the hawthorn and plum families is the fruit. The hawthorn yields little crimson haws, which are rudimentary drupes. From it the blackthorn, with its larger, more pulpy but astringent fruit, known as sloes, leads to the common wild plum tree, which bears a larger, juicier fruit, but one still scarcely suited in flavour to a civilised palate. By cultivation and selection all the varieties of garden plums have been produced from the sloe and wild plum. The cherry is an issue of the plum; the bird-cherry, with its currant-like bunches of little black fruits, is general in the north of England ; and the common wild cherry, with a fruit smaller but resembling the black garden cherry, flourishes in the southern counties. Lastly we have the large hardy trees of the apple and pear, the former of which may be almost regarded as our staple English fruit.

A. Graveson.

MEMORIES OF GHENT.

THREE weeks ago, from the time of writing, quite a large number of Britishers interested in horticulture could have been found hurrying off, viâ Ostend, Dover, or Harwich, to the agri-horticultural country of Belgium, with the intention of reaching the old city of Ghent in ample time for the opening of the fourteenth quinquennial horticultural exhibition held there. Not a few of these were invited to act as judges at the show, and such had to present themselves at the Casino early on the morning of Friday, April 15, hence their haste. Those who preferred comfort to the saving of an hour or two travelled viâ Harwich, by the Great Eastern Railway Company's service, and so enjoyed a good night's rest on board either the *Cambridge* or the *Ipswich*. From Antwerp to Ghent is not a far cry, and if the early train is caught little time is lost on the journey.

The greater part of Belgium is flat country, a country of verdant greenery, of moist atmosphere, of canals, bridges, and lines of trees. Trees line the roads and canals, and a large number of them belong to the Government; from trees of any age at all the branches are removed up to a height of fifteen to twenty feet, so that progress is not impeded, and small boys do not find it an easy matter to damage the lower branches. The majority of the trees that grow in the towns, especially in the squares and open market places, are provided with a large iron grating that extends three or four feet on all sides of the base of the trunk, and thus prevents damage to the bases of large roots, and affords an opportunity for giving a considerable amount of water to the trees should they need it, and this opportunity is taken advantage of. The soil of the Belgian lowlands is so light and easily worked that no one seems to think of putting foot to a spade when digging; the large heart-shaped spades used would frighten half our garden labourers at home, and indeed they would be unmanageable in some of the stiffer soils found in our islands.

Ghent itself is the centre of an extensive nursery trade, and in it and its suburbs there are over three hundred nursery establishments of varying size, some of them very large and well kept. In very few, however, is there any very large variety of plants cultivated, the general principle is special culture; and the chief subjects grown—grown well and in enormous quantities—are bays, palms (chiefly kentias), azaleas, araucarias, dracænas (largely D. lineata and varieties), anthuriums, and a few other aroids, and bromeliads (chiefly nidulariums caraguatas, and vriesias). Huge ridge and furrow houses are now the order, and their contents are certainly wonderfully vigorous and well furnished. In a comparatively few establishments hard-wooded plants are largely cultivated, and in such are to be seen regiments of Citrus sinensis—the Otaheite orange, ficuses, aspidistras, and Phormium tenax and its variegated form. Whither go all these plants? is the question that naturally arises. They go north, south, east, and west; bays and big palms to Russia and Northern Germany; palms, araucarias, and anthuriums to our islands and many continental countries; azaleas go to almost every country in Europe, and so we might continue. Belgium does a large home trade in plants, but a vastly larger one abroad.

About the wonderful exhibition at the Casino and adjoining galleries and hall little need be said after the comprehensive and amply illustrated report provided by the GARDENERS' MAGAZINE in its issue of April 23. It seemed to the writer that the magnificent azaleas were too dazzling, and placed too close together for artistic effect. Coming from the gallery out on to the staircase head in the annexe the breadth of azaleas made one's eyes blink again. Perhaps Mr. Pynaert, who is the landscape gardener of the exhibition, will think of some means of preventing such an expanse of vivid colours from being apparent all at once upon the next occasion. The effect in the Casino was splendid—restful greenswards, towering palms, luxuriant aroids, bristling cycads, gorgeous orchids, falling water, placid pool, rustic bridge, winding paths, all combined to make up a real garden of pleasure for the visitor, even though such arrangement was a bit hard upon the journalist.

The two most-talked-about plants at Ghent were Acalypha Sanderi, with its long crimson tails, and a huge pyramidal specimen of Dracæna Sanderiana; both these were grown at St. Albans by the firm whose name they bear, and no doubt visitors to the forthcoming Temple Show will also talk a good deal about them. Orchids from Brussels and Bruges were excellent in variety, though small in growth; the odontoglossum from the Walton Grange collection, however, surpassed all others shown. Two hybrid orchids of considerable merit were staged by the raiser, Mons. Maron, Brunoy, who also raised Lælio-cattleya Lady Wigan, shown at the Temple Show of 1897 and figured in the GARDENERS' MAGAZINE of May of that year. Lælio-cattleya Henry Greenwood was the chief newcomer, and it derives its origin from C. Hardyana and L. elegans var.; it combines the habit of both parents, and has large cattleyoid segments. Cattleya Louis Chalon is the other hybrid, and one obtained by crossing C. Trianæ with C. Lawreanceana, an interesting and very free-flowering hybrid with large rosy-purple blooms. Both these hybrids have crossed the water and become the property of Messrs. Charlesworth and Co., Bradford.

Among those Britishers who took part in or visited the Ghent Quinquennial, the London nurserymen figured largely. Ould Oireland was well represented by Messrs. Moore and Burbidge; Auld Reekie sent Professor Balfour, D. Laird, and D. Thomson, and perhaps some others. The Kers, père et fils, went from Liverpool, and Kew sent its Assistant Curator and orchid expert. The horticultural pressmen were very evident, and it was a difficult matter to escape the stalwart presence of the Editor of the GARDENERS' MAGAZINE, for, to use an Americanism, he was "there or thereabouts" whenever anything of consequence occurred, as the report showed. Not the least interesting matter in connection with this exhibition was the large number of Kewites present; old memories were revived and notes compared by Messrs. F. Ashton, F. W. Burbidge, E. Cooper, C. H. Curtis, K. Drost, J. Fraser, R. A. Rolfe, F. Sander, R. H. Pearson, L. Piret, L. Pynaert, W. Watson, J. Weathers, and J. F. Wilke. It is a sign of the influence Kew is continually creating upon matters horticultural, for here were nurserymen, gardeners, curators, botanists, and pressmen. Possibly there were other Kewites who paid a flying visit to Ghent.

Courtesy and attention to those who in any way assist them is shown and given freely by the executive of the Ghent Quinquennial, and in these matters some of our leading horticultural societies have much to learn. The hospitality of the Royal Agricultural and Botanical Society of Ghent was profuse, and all who partook of it felt they were being honoured. It did not perceptibly lessen one's expenses, but it acted as a lubricant to the machinery of human nature, and every one, officials, exhibitors, judges, and journalists, felt constrained to do their very best, and they did it. At Ghent one is reminded that "Love lightens labour," with respect to horticultural exhibitions as well as individuals, and if the "love" has some ulterior motive, the latter is not made glaringly apparent; all ends are served, and everyone feels happy and pleased with everyone else. May the good folks of Ghent and neighbourhood prosper!

Besides its nurseries Ghent has a large flower and plant market held among the trees in the Place d'Armes. Here some of the poorest of the Gantoise may be seen purchasing a few flowers, ivy growths, &c., for home decoration, a pot plant for the window, or some perennials for the tiny garden. Folks of the better class also saunter among the stalls and pick their way amid the scores of burly draught dogs; they, too, make purchases, and about the breakfast hour may be seen carrying home their treasures. About mid-day the market closes, and soon the remaining plants, flowers, seeds, &c., are carted away, and the square is soon swept and watered. From the railway station en route to the Casino one could not fail to notice the number of plants in the windows of houses of all classes; among the better working classes the most popular window plant would seem to be Impatiens Sultani.

It is frequently urged that it would be impossible to organise a big show at home lasting for a week, as the nurserymen and others would not allow their exhibits to remain for such a length of time. This is an erroneous idea, as proved by the Ghent Show, where at least five representative British nursery firms staged extensively, and several of them did not compete for prizes. One English and several continental amateurs of spirit sent choice orchids, and these remained throughout the exhibition. What can be done in Belgium can be done here if only there was a little more cohesion among horticulturists. There has been no really great horticultural display in Britain since 1866, and there does not appear to be any likelihood of growers showing their real strength until the R.H.S. celebrates its centenary. Where such exhibition will take place is a matter already exercising the minds of not a few, for it should be on a scale sufficient to surpass anything of the kind ever before held in this or any other country.

Nothing in Belgium generally, and Ghent particularly, strikes the British stranger more forcibly than the high social status of horticulturists, both amateur and professional. Many notable Belgian horticulturists hold high rank by reason of their birth or merit, and we can find parallels to these at home. But over there the head gardener of any importance is treated like a count, provided his education is good—the general rule; and the nurseryman who has been diligent in business may not only stand before the king, but converse with him, while in his native town or suburb he is looked up to instead of being regarded as "merely the nurseryman." Such men do not give themselves airs, they carry their honours modestly; you meet them at the banquet or raout with the Order of Leopold, or some other decoration in the buttonhole of their swallow-tail coat, and next day you find them at the garden or nursery with soft hat and blue blouse on, busy among the plants or in the office. Our national pride would probably not allow us to do this, and, perhaps, we should kick over the traces if honoured in any way. So it may be these things are best as they are, though those sixty persons who can attach V.M.H. to their names have not given evidence of insanity as some considered they would after the conferment of the order. SERVATOR.

PEAR BEURRE DE JONGHE.

MY gardener has called my attention to a recent article in the GARDENERS' MAGAZINE by Mr. Prinsep, and I should not write, but that the writer says he never ate a good Beurre de Jonghe pear. We have about fifty or sixty pear trees, almost all either espalier or pyramid, and the second best pear we grow is Beurre de Jonghe. It wants picking before quite ripe, but not before the sun has given it a tinge of colour, and then at Christmas it is difficult to beat. I planted nearly all my trees fifteen to seventeen years ago, and tried to plant sufficient varieties and of the sorts to give a dish eight months in the year. A mistake, for if I had to plant again I should take about eight of proved excellence, and be content. My trees are worked both on the quince and the pear. I enclose a list of our kinds as they ripen, with a word as to the quality: Citron de Carme, for the children; Jargonelle, good; Williams, good; Durandeau, most excellent; Marie Louise, very fine; Seckle, delicious; Beurre de Capiaumont, some seasons first-rate; Thompson's, watery; Louise Bonne, very rich; Josephine, sometimes good; Ne Plus Meuris, good in a hot year; Beurre Superfin, excellent; Winter Nelis, splendid; Beurre de Jonghe, next to Durandeau for quality; Beurre d'Esperen, on pear excellent, on quince worthless. I have a dozen others, but they are not of much consequence. T. N.

Shiplake, Henley-on-Thames.

PYRUS SIKKIMENSIS.

A VERY distinct and pretty Himalayan pyrus is the one figured in the present issue—P. sikkimensis. It is perfectly hardy in this country, for its home is at an elevation of from seven to ten thousand feet upon the Sikkim Himalayas. There it attains a height of from twenty to thirty feet, and develops into a stoutly branched tree. In June and July the rose-coloured buds expand, and the whole tree is covered with white, for the inner surfaces of the petals are white, with the very faintest suspicion of rose near the margins. The flowers are borne in corymbs, each is an inch or so across, and carried on a pedicel about two inches long. The ovate leaves vary from three to five inches in length, they are acuminate, and have serrated margins, while the under surfaces are slightly tomentose. In September the small red fruits, speckled with white, ripen, and have a very pretty appearance; these fruits are edible, but not particularly palatable, though Sir Joseph Hooker, who sent home seeds in 1849, states that he made an agreeable stew of them when botanising in the Himalayas. An old tree of Pyrus sikkimensis in the Arboretum at Kew flowers annually in May, a month or so earlier than the species blooms in its native habitat. Though Pyrus sikkimensis differs from the two other Himalayan species, the wild apple and the Siberian Crab, yet, like them, it belongs to the Malus group of the genus pyrus. Horticulturally the species has been known as Pyrus baccata indica, but its true name is that under which it is now figured, one given by Sir J. Hooker. The celebrated collector, Griffith, was the discoverer of this handsome spring-flowering tree, and the Kew Herbarium contains fruiting specimens sent home by him nearly fifty years ago.

SWANLEY AND EYNSFORD.

A VISIT to the two establishments of Messrs. H. Cannell and Sons is at all times interesting, but at no season perhaps is it attended with more pleasure and profit than in the spring. We not only then see the Kentish orchards amid which the nurseries are situate in their more attractive guise, but a considerable proportion of the immense collections of plants in the open and under glass are in bloom, and by taking note of the work in progress in the packing sheds it is not difficult to gauge with some degree of exactitude the trend of public taste in its relation to the garden. It would appear that such things as zonal pelargoniums, tuberous begonias, and dahlias, which have long formed special features at Swanley, have in no way decreased in popularity, for house after house is filled with them. and the great array of cases filled with pelargoniums ready for despatch is the best possible proof that Messrs. Cannell do not grow them wholly for their own entertainment. We have evidence also that herbaceous calceolarias, cinerarias, cyclamen, gloxinias, and Chinese primulas continue to increase in popularity, for the area devoted to these plants continues to extend both at Swanley and Eynsford, the object of their culture being, of course, the production of seed. While these and other important classes of ornamental plants continue to do something more than hold their own, other sections have made their wa to the front; and as the firm is always ready to recognise the merits of novelties the new races of cannas, carnations, violas, and other groups of plants are strongly represented, and the enormous stocks of the cannas grown for the beauty of their flowers are sufficient proof that these highly ornamental plants are much appreciated by the flower-loving public.

The collection of cactaceous plants at Swanley is of interest as indicating the change which public taste has undergone with regard to these plants of late years. A comparatively short time since they were so neglected that the trade in them practically died out, and at Swanley a small structure sufficed to afford accommodation for the collection, which was retained more for the entertainment of the senior member of the firm, who has at all times evinced the keenest interest in his old favourites, than for business purposes. Now these interesting denizens of the vegetable kingdom bask in the sunshine of public favour, and enjoy a high degree of popularity. They have a society and a journal wholly devoted to them, and a brisk demand has sprung up for both choice and ordinary kinds, with the result that the Swanley collection requires a house one hundred and fifty feet in length by about twenty feet in width, besides other structures of smaller size, for its accommodation. One might well be excused for lingering in the principal structure devoted to the cacti and other plants usually associated with them, discussing their peculiarities of structure and their cultural requirements, and still greater is the temptation to refer to them at considerable length. But time presses, and the demands on our space are so heavy that the temptation has to be resisted, and mention made of the more noteworthy kinds only and in the fewest possible words. The mamalarias form a large and interesting group, many of the species being decidedly handsome. Of these the first to attract attention were M. lasicantha plumosa, a distinct variety, remarkable for its dense white down-like covering. M. pusilla is distinguished for its bright red fruits, which are freely produced, and remain in good condition for a considerable period. M. Newmanni attains a large size, has long white spines, and produces rose magenta flowers. M. Pfefferi is of medium growth, with pale yellow spines. M. stella aurata presents a striking contrast to the foregoing, for it grows in dense clusters and each plant when fully developed does not exceed an inch or so in diameter. The echinocactus includes several eminently attractive forms and chief among those of which note was made are E. Grusoni, a striking plant of large growth liberally provided with stout yellow spines, and E. scopa a distinct species with slender cylindrical growths tinted rose at the apex. The cereus are very distinct from the foregoing and contribute materially both to the interest and attractiveness of the collection. C. macrogonus has distinct blue-green fluted stems; C. flagelliformis is remarkably vigorous with long snake-like shoots; and C. peruvianum monstrosum has its growth much crowded and presents a very singular appearance. The opuntias with their flat spiny growths are by no means wanting in attractions; and O. macrodasys and O. leucotricha, both of which are thickly studded with slender yellow spines, are decidedly handsome. Pilocerus senilis and P. Dautwitzi may be mentioned as the most handsome species included in the genus; both are covered with long white hairs, and produce a striking effect in association with the other types. Especially attractive among the smaller growing agaves are Agave Victoria Regina, and A. filifera, and of the many beautiful echeverias mention must be made of E. agavoides, a dense-growing silvery-grey species; E. farinosa a slender-growing species of a bright silvery hue; and E. metallica crispa a distinct form of this well-known succulent with leaves somewhat frilled and elegant in character.

The several houses devoted to zonal pelargoniums are, as usual, aglow with colour and afford abundant entertainment to those that are at all interested in this showy and exceedingly useful class of plants. If the advance in new varieties is less marked than was the case twenty years or so ago the novelties evince a material improvement upon established varieties in the several lines of colour. To mention a few of these it must be said that Crabbe is a superb salmon-red variety, the flowers large and of fine form, and borne in noble trusses; C. C. Tudway crimson-scarlet with bright glow of rose; and Mrs. Tuke bright rose red and of exceptional merit. Madame Alcide Bruneau is an exquisitely beautiful double zonal of neat growth and bearing a profusion of well formed trusses, the flowers are white, the petals margined with a well-defined line of deep rose, as in the case of the florist's picotee. As the forerunner of a new and beautiful race this variety is well deserving of special attention and should be generally grown.

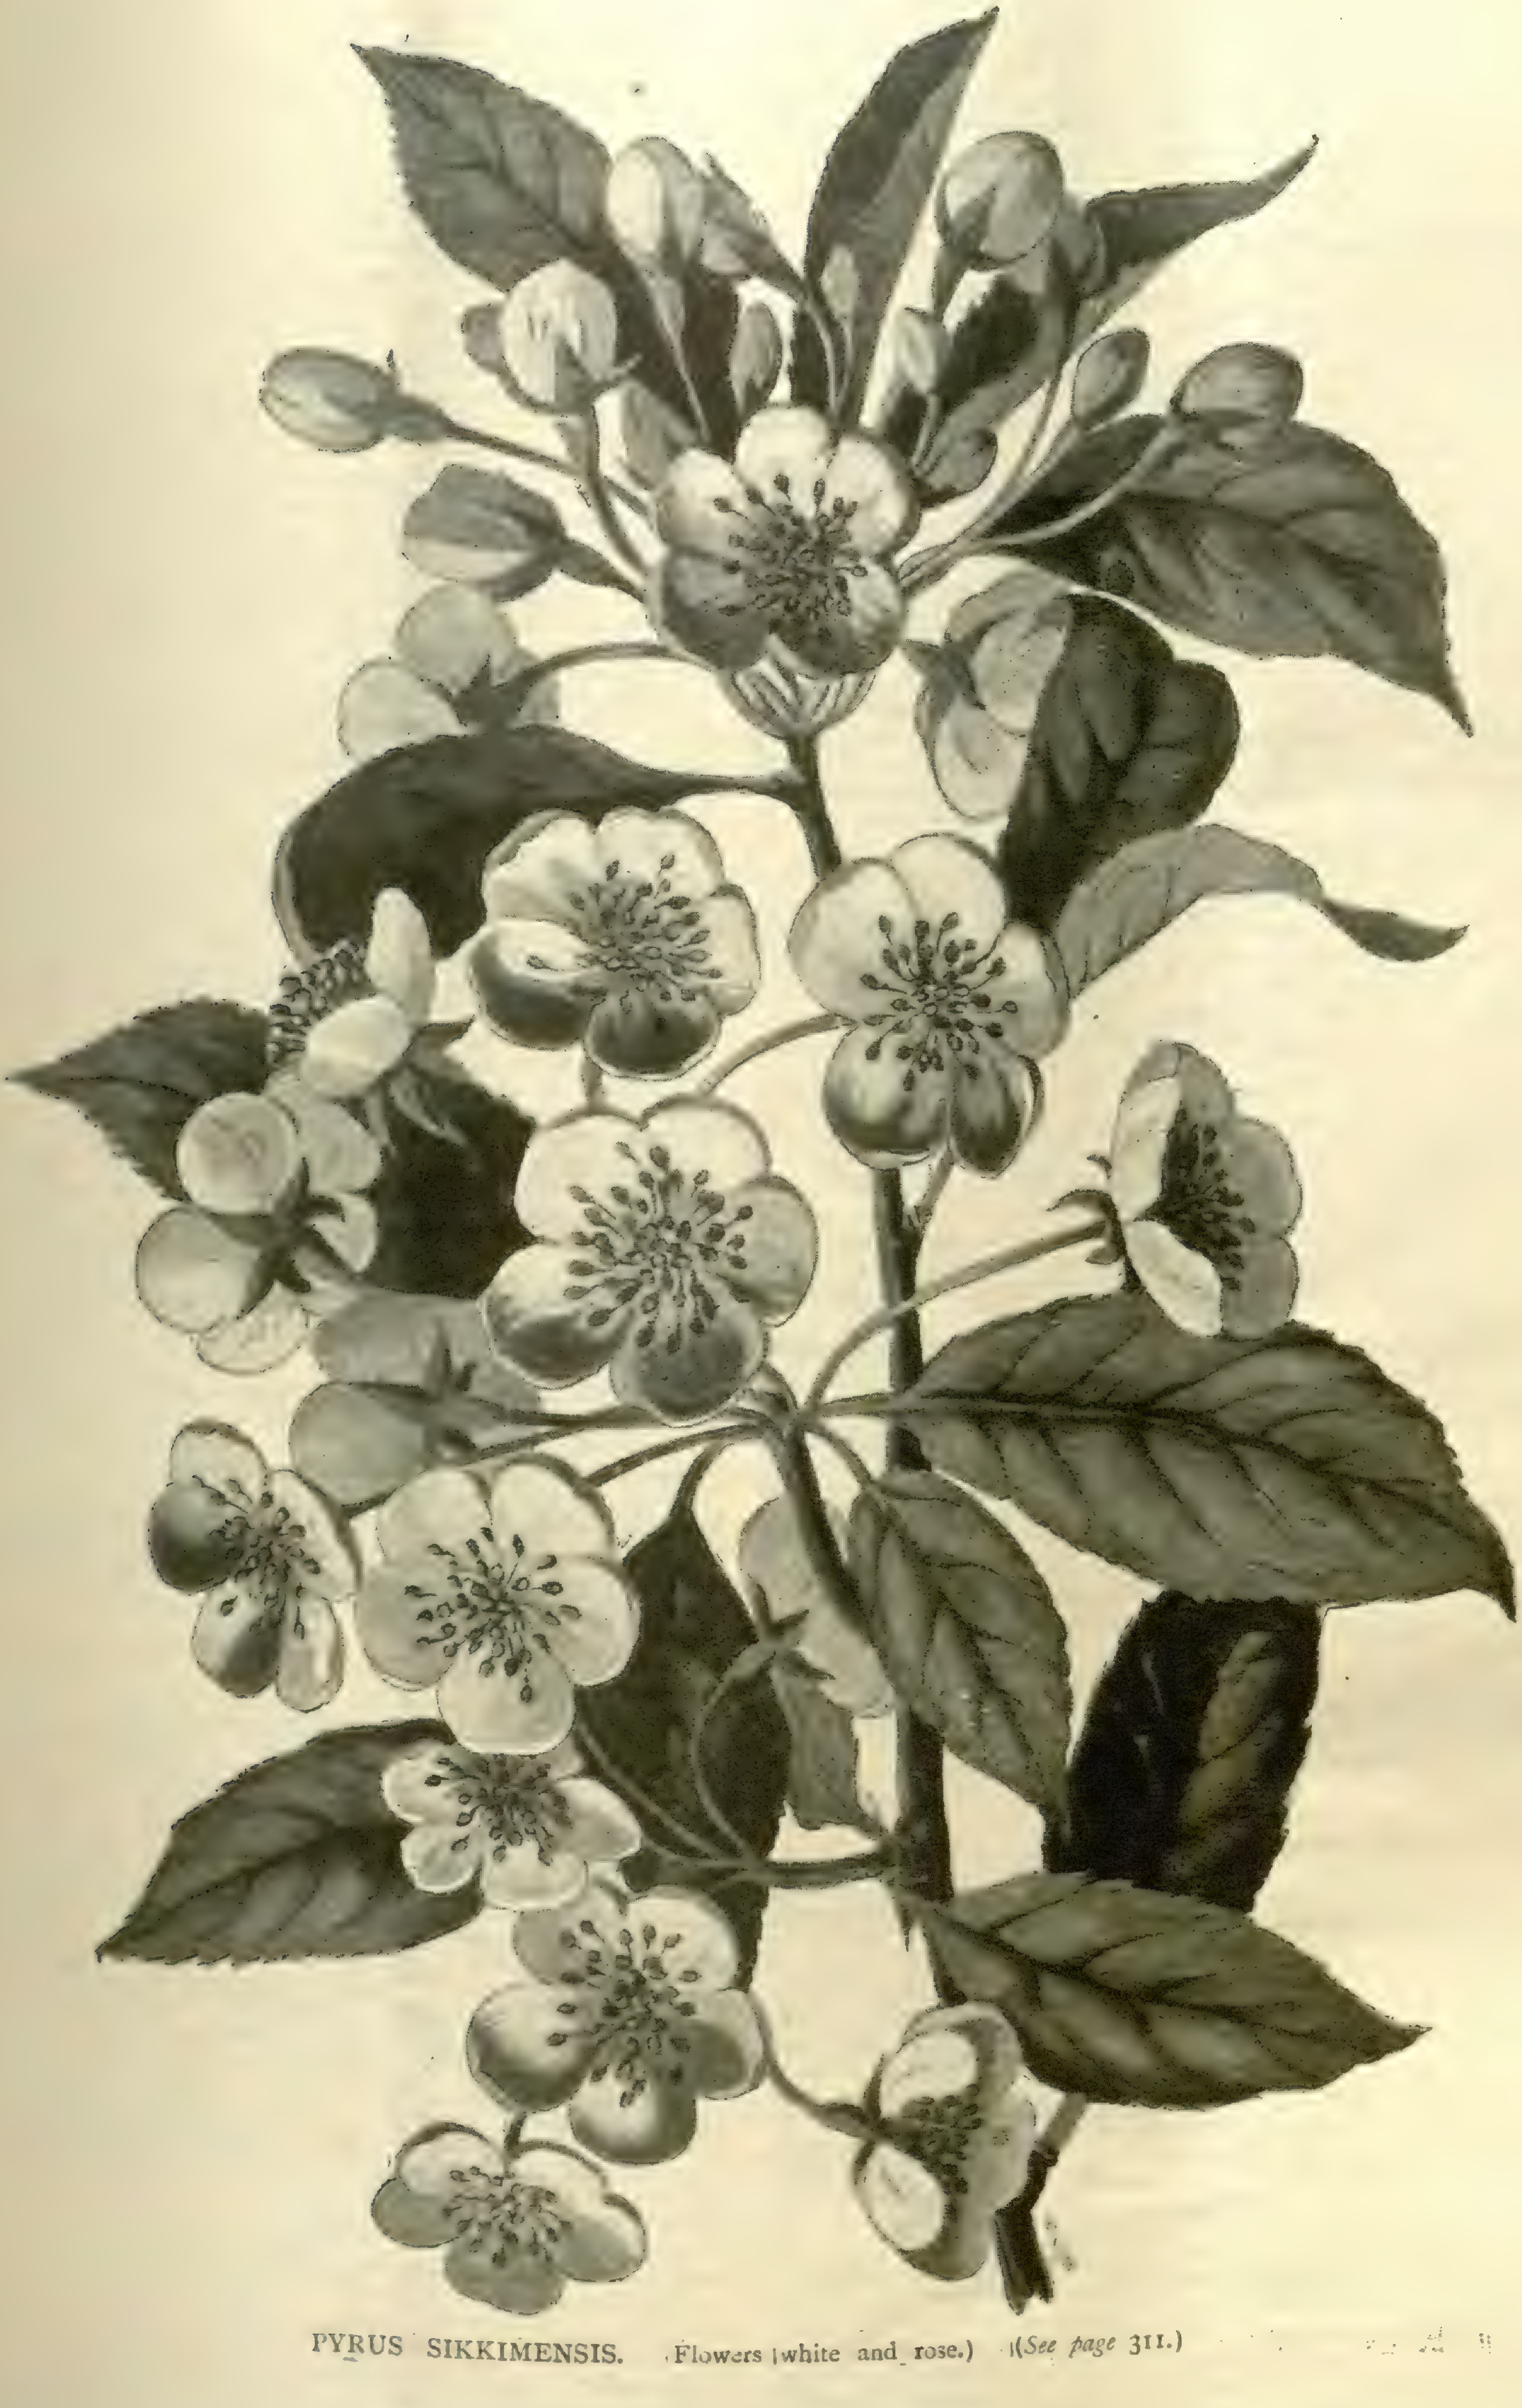
The five or six spacious span-roof houses devoted to Chinese primulas are more interesting than beautiful just now, for the plants are bearing a heavy crop of seed with a stray bloom here and there to remind one of the glorious display of colour produced when the thousands of plants were in bloom, and also of the great diversity of colouring included in the Swanley collection. Especially interesting are the large blocks of plants of the tall-growing and elegant race of which The Lady may be regarded as the type. This elegant primula is extensively cultivated, and associated with it are several beautiful forms that have been obtained by the intercrossing of The Lady with the varieties belonging to the ordinary type. Much success has already been achieved, and it is hoped to obtain a race that will combine the lightness and elegance of The Lady with the colours of the ordinary section. Purple Lady and Pink Lady are two of the best of the coloured forms, and Mrs. Robert Cannell is a charming white form with dark foliage; Messrs. Cannell have also made considerable progress in their endeavour to obtain a race of Chinese primulas with flowers remarkable for their large size and fine form, but borne in distinct whorls on stout stems instead of in dense clusters, and this progress is well marked in the variety known as Pyramidalis alba; in this the flowers are borne in pyramidal spikes fifteen inches or so in height. This and similar forms should do good service in bold decorations, and should be regarded as supplementary to, rather than rivals of, the orthodox types. The usefulness of the elegant varieties of The Lady type for grouping is well shown in the accompanying illustrations.

GROUP OF THE LADY PRIMULAS.

The beauty of the cinerarias is somewhat on the wane, but the magnificent collection, which comprises all the best of the varieties grown under name, is still highly attractive and interesting as a demonstration of the high degree of perfection to which these flowers have been brought by the florist. Here, as in the case of the primulas, Messrs. Cannell have been working assiduously to obtain a race somewhat more elegant in habit than the ordinary type, and by crossing the best of the florists' forms with Cineraria cruenta, they have raised several varieties that can hardly fail to acquire popularity when they are in commerce and become known. The herbaceous calceolarias are a strong feature here, and the immense collection is now rapidly coming into bloom, the richly-coloured flowers producing an attractive display. Gloxinias are commencing to flower freely, and the plants already in bloom give an excellent foretaste of the charming effect that will be produced later on.

The rapidity with which the large-flowered cannas have become popular is remarkable, and knowing how highly appreciated are their large, handsome, and highly-coloured flowers, we were in no way surprised to find at Swanley several spacious structures wholly devoted to them. Konigin Charlotte is still a great favourite, and Austria and Italia, which have flowers of the largest size, are likely to be planted in immense numbers during the current month. Tuberous begonias are to be met with in their thousands, and while on the one hand there are immense numbers coming into bloom, there are still larger numbers in the seedling stage. Begonias are, indeed, so largely raised that labour-saving appliances have to be resorted to, and we were much interested in the simple contrivance invented by the firm for facilitating the work of pricking off.

From Swanley to Eynsford is a pleasant drive of two miles, and the way for the most part is through orchards that gave promise of an abundant harvest this year, a promise that it is to be hoped will be fulfilled. Much might be said with reference to the Eynsford farm, which has proved so admirably adapted for the



PYRUS SIKKIMENSIS. Flowers (white and rose.) (*See page* 311.)

production of seeds. The crops have mostly been sown or planted, and with the assistance of recent rains are making good progress. In the houses and frames we noticed several hundred thousand plants of asters that were being hardened off preparatory to being planted out on the sunny slopes for seed production. It has been found that heavy crops of perfectly ripened seed can be harvested at Swanley, and the Messrs. Cannell are rendering a national service in demonstrating the practicability of producing aster seed at home, and thus making growers in this country independent of supplies from abroad. Immense quantities of stock seed are also produced at Eynsford, but the plants required for seed production are grown in pots and under glass to ensure their enjoying the climate that is to them essential in the production of perfectly-ripened seeds. The area under fruit trees has been greatly extended of late years, more especially for the manufacture of young trees; and roses, which occupy many acres of the fertile valley, are evidently quite at home, as, indeed, are all the occupants of this favoured spot.

PEACHES IN THE OPEN DURING MAY.

THIS month is about the most important in which to deal successfully with peach trees out of doors. Before stating the treatment we gave our peaches, I feel justified, in view of recent notes, in telling "Lux" that after having frosts every night during the time the peaches were in flower, we have now a very good set upon all our trees, and yet these have had but a very light protection—that of a single fish-net hung about two feet in front of the trees. We have a good set, and probably as good as those who delight in covering their trees thickly with all kinds of material, including large spruce branches.

During the first week of this month we cleared away all the fish-nets which were hanging in front of the peach trees, and as soon as this was done, the garden engine, one in which I had an especially strong pump fixed, was brought out. We next dissolved two pounds of carbolic soap in thirty gallons of water, and with this, in a lukewarm condition, we gave the trees a thorough good washing, using about thirty gallons to half-a-dozen trees. The following day we used this engine again, with a mixture of Richards' XL. All insecticide, at the rate of one quart to thirty gallons of water. These operations we shall continue at frequent intervals, until the trees are completely cleared of aphis. After the trees are clean and the weather gradually becomes warmer, the growths will make rapid progress, and each day will show great development.

Another operation of great importance at this time is disbudding. This must be done as soon as possible, and to do it well, some amount of practice is required. Commence by taking away all the front shoots, as these will not be wanted, except by those who grow peaches on the spur system. I well remember Mr. Frost, of Dropmore, used to pride himself on the fine peaches he used to have from trees in a peach-case that were spur-pruned, but the trees never looked tidy by any means. After the front shoots have been removed, then take away all the worst of those that are curled and burn them. Care most for the leading shoots and those at the base of the growths, leaving those naturally placed the best for training up for the next year. If more space has to be covered, of course leave shoots as required for the purpose. Disbudding should be commenced at once, and no time should be lost in effectually cleaning the trees from aphis, as good results depend upon starting the trees well at the commencement.

The next operation should be that of mulching, which should take place after the fruits have begun to swell, and then once a week, in addition to syringing, the trees should have a good watering. Especially should this be done immediately the second swelling, after stoning, has commenced, as they then need nearly all the liquid it is possible to give them. The mulch may consist of stable or farmyard manure, and should be laid on fairly thick—say, three to five inches—but this should be removed after the fruits are gathered. We mulch all our wall trees with stable manure (peat moss), and this is the only way we care to use this manure, for it is not very valuable to dig in.

For syringing the peach trees with the garden engine we have a long length of hose-pipe attached, so that the boy can pump from the walk, and the operator can use the hose quite close up to the trees, which is a great advantage. A man and boy can wash a number of trees in this way in a short time. We syringe our trees every day in hot weather, and use the engine both inside and out for peaches. Varieties on walls, which are full of promise now, are Waterloo, Amsden June, Dymond, Goshawk, Royal George, Princess of Wales, Sea Eagle, and Barrington.

Compton Basset.

W. A. COOK.

The Black Currant Mite.—It is interesting to note, arising from the grave complaint as to the ravages of this insect pest in portions of Kent, that our leading entomological authority, Miss Ormerod, seems to have no palliative to offer to growers other than in absolutely stamping out the plague by total destruction of bush and insect. That is a method of dealing with the pest that few growers on a large scale will care to face, and indeed would be utterly useless if conducted in isolated cases. No possible good could result unless wide areas were compulsorily dealt with, and it really seems, so far as this grave trouble is concerned, that local authorities will have to be granted powers to deal with infected areas just as they now have in the case of cattle diseases. But in this latter case some compensation for destruction of cattle in diseased areas is paid; whereas it will be difficult to adopt such a practice in relation to condemned fruit breadths, as it would be very unfair to the general ratepayer or taxpayer. Miss Ormerod thinks that the proper course to take where there are breadths of infested black currant bushes is to grub them out, root and branch, burn them, and crop the ground with potatoes or other vegetable or corn, and thus starve the mite out. That is all very well, but in the meantime there must be steps taken to maintain a supply of healthy bushes. How is that to be done? Are there any stocks in the kingdom absolutely free from the mite? If there are so much the better. But still, if propagated, these stocks must be kept a long way removed from other old ones for a few years: and to that end it seems needful to isolate them right in the midst of corn-growing-districts, a long way from gardens. Once get the mite into the clean young stocks and nothing would be gained. It seems a pity that the resources of science can furnish no other remedy for a great evil than is found in absolute destruction of stocks.—A. D.

THE GRANARD NURSERIES.

PRETTILY situated in the Putney Park Lane, a long, tree-lined lane that slopes from Putney Heath to a point close to Barnes Common, are the Granard Nurseries, belonging to Mr W. Iceton. If a charming position could ensure the success of an establishment, then one might easily have foretold Mr. Iceton's success, for at present the surroundings are beautiful. There is the delicate greenery of the budding lime trees down the lane; the deeper green of the grass in the meadows that slope away below Dover House and in front of the nursery, with here and there a thickly-foliaged horse chestnut bristling with flower-spikes. Behind and along one side of the nursery runs an orchard, chiefly of pear trees, and these at the time of our visit were a beautiful sight. There are very few houses to be seen from Granard; all is rural. Then, if the day be favourable, the cuckoo, thrush, blackbird, chirping sparrow, and a large variety of birds may be heard all round, so that it is difficult to imagine one is within a few minutes of Putney, and not far from Hammersmith, on the edge of the metropolis. It will be a thousand pities if Putney Park and Roehampton Lanes become ordinary suburban roads lined with houses, but at the present rate of progression towards the south-west greater London will no doubt soon seize them, and their present beauty will pass away.

Picturesque surroundings and pure air, however, have not built up the fine business at the Granard Nurseries, though they may have helped not a little in the production of the healthy, finely developed plants and flowers for which the establishment is noted. The builder is Mr. Iceton, who at the early age of seventeen years commenced business in a small way at Barnes. A moderate amount of success achieved there, coupled with a foresight that indicated the growing wants and necessarily increasing demand of the metropolis for plants and flowers, induced him, still quite a young man, to start on a large scale at Putney Park Lane. Here he started seventeen years ago, and by perseverance, skill, and a keen appreciation of the varying tastes of the great metropolitan public, has made for himself a name that is highly respected by the nurserymen and market growers both of our own and other countries. The establishment has been enlarged to meet the demands made, and it has flourished steadily. Mr Iceton, like other growers, has to meet also a keener competition than in years gone by, and if he does not obtain the high prices of earlier years he has a bigger output, and it is pleasant to find in him a genial gentleman, who is too large-hearted and too busy to be continually grumbling about the downfall of market growing and losses sustained. The profession could do to-day with fewer grumblers, and who shall say that Mr. Iceton's cheerful disposition and smiling face have not done almost as much to improve his position as have hard work and honest dealing? But to return. Only five more years may Mr. Iceton remain at Putney Park Lane, and already, as previously noted in these columns, he has obtained an estate close to Ravenscourt Park and Turnham Green, where very shortly some extensive ranges of cleverly planned glasshouses will be built for him by Mr. Duncan Tucker. This spot will eventually become Mr. Iceton's chief establishment, and as he is but now in his forty-seventh year, and has thirty years' experience behind him, there is little doubt but that, with continued health and strength, there is a fine prospect before him.

To many of our readers Mr. Iceton's name is indissolubly joined, in thought, with palms and lily of the valley. These certainly are the most extensively grown subjects at his nurseries, though several others run them close. Of palms there are dozens of large light houses filled with all the most popular sorts that are in demand for house decoration; under the stages are hundreds of thousands of seeds in various stages of germination, and on the shelves close to the glass are whole armies of seedlings clean and thrifty, and eager to develop sufficiently to take the place of the larger plants as they pass out day by day. There are splendid stocks of the handsome Kentia Forsteriana in all stages from the seedling with its one cotyledon up to tall and spreading specimens that would grace the finest conservatory or winter garden. Kentia Belmoreana, Latania borbonica, Livistonia rotundifolia, Phœnix reclinata, P. tenuis, and P. rupicola, the beautiful Cocos Weddelliana, and taller but not less graceful Cocos plumosus, Areca lutescens, A. sapida and A. Baueri, Rhapis humilis and R. flabelliformis—these are the palms most in demand and seen here in huge quantities, every plant a perfect one for its age. Mr. Iceton has a few pets, and among these are some exceptionally handsome Phœnix Roebelini, possibly the most beautiful of all the Date palms; Geonoma intermedia variegata and Livsitonia aurea, two kinds in which the foliage is distinctly and curiously coloured as the names suggest; and Calamus (Dæmonorops) palembanicus. These the proprietor cares for with the interest of a plant lover rather than of a market grower. Seaforthia elegans is grown but not extensively, as it is a palm that has long since been superseded for home decoration.

Some half-dozen or so of houses are devoted to lily of the valley in various stages of development; you may see the cases of crowns newly arrived from the cool storage, every crown fat and firm and with no trace of suffering from an artificially prolonged winter. Then you pass to darkened houses where newly boxed up crowns are being coaxed into flower and growth; further along the spikes have been produced, and so the various stages can be viewed up to the fully developed spikes of twelve or fourteen large and pure white bells that will to-morrow morning go to Covent Garden, to Bristol, may be to Manchester and elsewhere, to subsequently adorn the corsage of "my lady," to fill the button-hole of the man who goes to the City, to emit their exquisite fragrance in the home, to help make up the bridal bouquet, or perchance to act as tokens in loving memory of some who have passed hence. About two and a half million lily of the valley crowns are grown annually by Mr. Iceton. He has them flowering all the year round; for this beautiful flower he has a big reputation that he is careful to sustain. Tulips are largely grown, but of course have been distributed weeks and months ago. Quantities of the elegant Spiræa japonica are seen, some quite green, but others crowned with snowy plumes. Liliums abound in frames, pits, and houses, and probably not less than fifty thousand are grown each year; the great bulk of this quantity consists of Lilium longiflorum eximium, a variety that is pushing L. Harrisi out of the market, because it is more robust and the flowers more substantial. The climate of Bermuda seems to have weakened the constitution of the famous L. Harrisi; or is it the lack of high cultivation? Whatever the reason the variety is not what it was, and is being passed over by market [illegible]. Some idea of the large number of liliums grown may be gathered from the fact that in the height of the season flowers to the weight of two to three hundredweight [illegible] leave the Granard Nurseries on a market morning. L. Harrisi, L. longiflorum, and L. lancifolium are other lilies grown in quantity. Azaleas, and a few oranges, are cultivated chiefly for providing flowers to meet the home demand.

Dracænas naturally occupy a large number of houses, and the large [illegible] of handsome specimens of D. Lindeni, D. lineata, D. l. variegata, D. Sanderiana, D. Doucetti, D. terminalis, &c., are eye-openers with regard to high cultivation. Eurya latifolia variegata is a popular and handsome plant, whether small or large; it, and euonymuses of sorts, may be numbered by thousands; so also [illegible]

Aspidistras, Ficus elastica, both green and variegated forms; Pandanus Veitchi, finely coloured; Asparagus plumosus and A. p. nanus, Araucaria excelsa, splendidly furnished; Bambusa gracilis, and Selaginella Kraussiana, the latter grown in shallow pans and just now in fine condition. Asparagus plumosus does remarkably well here, and in two pits and one long house it seeds freely, so that Mr. Iceton supplies seed both to home growers and to continental and American nurserymen; the fronds, too, develop finely, and are marketed freely. A few notes on choice caladiums, of which Mr. Iceton has a rare collection, will form a conclusion to this brief notice. For many years all the best and newest varieties have been obtained and well grown and coloured, so that now those in search of choice and new forms will find at Putney Park Lane an almost unique collection. A few of especial note and now developing quickly are Pres. de la Devansay, richly coloured; Ronura, a silver and green form with distinct foliage, in which the basal lobes are missing; Silver Cloud, a beauty, and well named; La Lorraine, now becoming fairly well known; Guill Mar, of a light, transparent pinky shade with dark purple veins, very choice; Rio de Janeiro, pale transparent rose; Rayon d'Or, one of the best greeny-gold forms; Imperatrice Teresa, white and pink with deep purple veins; Mrs. W. Iceton, creamy yellow with whitish blotches, very handsome; Princess Olga, deep crimson; Princess of Teck, carmine centre surrounded by greenish-yellow; Her Majesty, golden green with deeper veins; Roncador, deep green and spotted with white; Flamont Rose, a blunt-pointed German variety, crimson veins and deep rose shading and mottlings; Leon Saye, a variety that has shown some remarkable reversions and variations; Sir Henry Irving, large white centre with green mottled margins; Lady Northcote, Mrs. J. McLeod, quite new; Lord Derby, Lady Moseley, and Donna Carmen Macedo. Besides all the other interesting matter to be found at Putney Park Lane, and the quantity and quality of everything growing there, the nurseries of Mr. Iceton are well worth a visit, if only for a sight of these beautiful caladiums, mostly represented by medium-sized plants.

NARCISSUS AT VALLEYFIELD, PENICUIK.

THE proprietor of this establishment, Alexander Cowan, Esq., has long been known as a collector of these handsome spring-flowering plants, and an enthusiastic cultivator. The collection of narcissi is a large one, and the genus is well represented in all its sections, from the older varieties down to the new seedlings. The garden lies in an interesting district in the valley of the Esk, and is reached by a quick service of trains on the North British Railway, being about fifteen miles out of Edinburgh. On the way we pass the pretty and historical districts of Rosslyn and Hawthornden, both popular with visitors to Edinburgh. The garden lies in the valley, and although not of large dimensions is of varied interest, and in close contact with large paper works, of which this genial proprietor is owner.

When entering the garden of late one was at once presented with a grand display of yellow tints from the large quantities of daffodils growing in beds upon the flat ground, where they have been cared for by the gardener, Mr. Shillington. The greater quantity of the newer kinds and good varieties appear to be grown systematically in beds, in lines, in which manner of cultivation they are easily attended to. The first to attract is the magnificent Madame Plemp, a striking variety with long yellow trumpet tube, and apparently a strong grower here. Another of this section is Weardale Perfection, certainly the largest and most handsome flower of its class, and an expensive plant; near by is J. B. M. Camm, a chaste form, the pale yellow of the throat being very pure. The variety Victoria, offered in 1897, is doing well, being of a bold habit, with a beautifully fringed trumpet; Lady Somerset is a tall grower, and robust, with a remarkable twist in the perianth. One of the most telling in growing *en masse* is Duchess of Westminster, which is here in a large clump a yard or more through, and conspicuous among the whole break; it is a Leedsi form, and the blooms are white in the perianth, with an orange-tinted yellow cup; Marie Magdalen de Graaf is also a distinct and good variety of the same class, and late in flowering. Barri Conspicuus is in favour here as elsewhere, while others of this section noticed were Flora Wilson, with pure white perianth, the cup, edged with a bright orange ring, giving it a striking effect; Maurice Vilmorin, a dwarf form, was also in good condition.

Upon the banks of a dam patches of N. scoticus plenus were at their best, and the picture of vigour, their situation upon this cool slope evidently suiting their requirements. Madame de Graaf is a large variety, and very conspicuous; it gained a first-class certificate in 1896. Mrs. Vincent, Snowflake, W. P. Milner, a very dwarf plant, and William Goldring, all trumpet daffodils, attract attention as we pass. Of the incomparabilis types many are growing extremely strong here, and those noted were Commander, Hogarth, Lulworth, and Mabel Cowan. Natural plantings of narcissi are carried out extensively, and the site chosen is one well calculated to show them off to the best advantage. This is a high bank covered with trees up to the summit, and between these the many daffodils are revelling. The colour of the narcissi is heightened by a groundwork of ivy, which here and there covers the soil. At the base of the bank are planted large beds of Lord Penzance's hybrid sweetbriar roses.

Everything connected with this garden is in good order, and, under the management of Mr. Shillington, kept scrupulously clean. The houses contain some good plants in bloom, while the vineries give promise of a good crop of bunches. But as our visit was more especially to enjoy the narcissi, we leave this department, convinced that all who have the pleasure of visiting Valleyfield in spring will be well repaid. H.

Ramondia pyrenaica.—I have never seen this charming alpine flower so well as this season. Some large plants here are bearing six spikes, each spike carrying four, and, in some cases, five flowers. In a moist shady position, occupying the sloping crevices of the rocks in peaty soil, this Pyrenean primrose flourishes in a surprising manner. The flowers are of a pretty violet-purple hue, with a bright orange eye. The white-flowered form is later with me this season, and only just commencing to bloom.—E. SCAPLEHORN, *Woking.*

WORK FOR THE WEEK.

COOL ORCHIDS.

FIRE heat should now be dispensed with in the cool houses except during cold nights, such as we are having here at the time of writing, when a little heat should be afforded, opening the valves a little in the evening, and closing them again first thing in the morning. When these spells of cold weather prevail it is far better to allow the temperature to drop a few degrees than to use much fire heat. The sun heat now being very strong heavy shading will be necessary to keep the houses as cool as possible during the day time; all the blinds should be raised a foot or so above the glass, thus enabling a good current of air to pass beneath, and so greatly reduce the power of the sun upon the glass. The shading should be removed as soon as the sun has lost its power in the afternoon. When the outside conditions are hot and dry the hose should be freely used, damping down every available space two or three times daily. A slight spraying overhead may be given the plants with advantage after a day's hot sunshine, taking care to use soft water. Odontoglossum cuspidatum xanthoglossum now in flower is a very distinct and brilliantly coloured orchid; it has long branching racemes of golden-yellow flowers, the sepals and petals being blotched with chestnut brown, and the lip having a large reddish-brown blotch at the base; plants of this, after passing out of flower, should have a little of the old material carefully picked out, resurfacing them with a little fresh sphagnum moss. Cymbidium Lowianum and its hybrids, that have had their flower spikes removed, should now be repotted or top-dressed as required, using the same kind of compost as advised in a former calendar; after repotting these plants should receive a thorough soaking of water to settle the soil about their roots, but after this very little water will be needed until the new roots have a good hold of the compost, when more should be given. On bright days it will be beneficial to syringe these plants night and morning, but care must be taken not to allow the water to lodge in the partially developed growths, or injury may follow. Oncidium tigrinum is now commencing to grow after a long rest, and a little new material should be given, consisting of equal parts of peat and moss; water should be given sparingly until the flower spikes make their appearance in the young growths, when a more plentiful supply will be needed until the bulbs are made up.

Plants of Dendrobium infundibulum and its variety, Jamesianum, are now commencing to root freely, and new material should now be afforded them, repotting or top-dressing as each particular case demands, using a compost of equal parts of peat and moss. Pot-shaped teak-wood baskets should be used, as I find these dendrobes root more freely in them than in pots or pans. Anguloa Clowesi and A. Ruckeri are now growing freely, and should have a plentiful supply of water, with an occasional dose of weak liquid cow-manure; the leaves should be frequently sponged, to keep them free from scale and red spider. Lycaste cruenta and L. aromatica are showing flower buds from around the base of the new growths, and any of the plants that require repotting are best attended to at this stage, for, like anguloas, if left until blooming is over, the new growths will be far advanced and probably be checked; these plants require a liberal supply of water during the growing season.—E. SHILL, *New Hall Hey Gardens.*

STOVE PLANTS.

YOUNG plants of crotons, ixoras, dracænas, &c., which it is desired to grow into specimens in the shortest possible time, must be shifted into larger pots directly they have filled the previous pots with roots. Should they be left too long in the small pots growth becomes restricted, and do what you will afterwards it is impossible to obtain that necessary free growth. Too large shifts are not advisable, as, unless the watering is very carefully attended to, disaster will ensue; small and frequent is the better policy—in this case, there is not so much danger of sour soil. Pot up successional batches of gloxineas, tydæas, achimenes, &c., and afford stimulants to those showing their flower buds, giving either diluted liquid or an occasional surface sprinkling of some good artificial fertiliser. Any variety of gloxinea, of which it is desired to increase the stock, may be readily propagated by means of the leaves. Cut those leaves which are fully developed, sever the midrib in several places, and lay them underside down on the surface of pots or pans of sandy soil. It is necessary to keep the cut surface in contact with the soil by means of small stones laid on the leaf, or by thin wire pegs; place in a propagating case, but do not keep too close or moist else damping will occur. Should all go on well, in a few weeks a bulbil will form in each place where the midrib was severed. Seedlings of gloxineas, saintpaulia, didymocarpus, tydæa, and other things, which were pricked off into pans a few weeks ago, should be potted off singly directly their leaves touch in the pan. Push forward the propagating of poinsettias and euphorbias, taking daily those cuttings which are fit—cuttings that are more than four inches long I do not favour; three to four inches is a suitable length; insert singly in thumb pots of sandy soil, and plunge in a brisk bottom heat. While keeping up a moderate amount of atmospheric moisture around the cuttings beware of damp; this can be obviated to a certain extent by allowing the cuttings to stand clear of each other in the case; damping generally commences when two or more leaves overlap each other. Pot on coleus as they fill their pots with roots, not allowing them to stand long in one pot until they are placed in the largest size they are to be allowed. We have only three varieties which we keep to propagate from cuttings, these being favourites in thumb-pots for dinner-table decoration; the remainder we raise from seed annually, and by this means we have not to use up valuable space during winter in storing old plants.

As the foliage of caladiums attains to full size it should be afforded support, by means of light stakes on thin pieces of wire, to which the foliage should be looped by means of raffia; the plants also, as they fill their pots with roots, should receive weak stimulants occasionally. Peperomias may now be increased freely from cuttings, short pieces of the shoots being severed with a sharp knife and inserted in sandy peat. If they are placed in the propagating case they must not be kept close, but plenty of air allowed them; P. argyreia is the most serviceable. Bougainvillea glabra will now be showing its flower-buds, and should receive stimulants regularly; thinning of the shoots should be attended to when very thick, as the results will then be better, and a second crop of flowers more readily assured. Care will be necessary in watering basket plants to see that the soil is moistened throughout, an occasional dip into a tub or tank will ensure the thorough moistening of the whole body of the soil. Among ferns most suitable for baskets are Adiantum cuneatum, A. caudatum, A. assimile, Nephrolepis tuberosa, N. exaltata, N. davallioides, and davallias in variety; and in places where there is a large grand staircase to be furnished, nothing looks more noble than large baskets of Woodwardia radicans. Ferns of all kinds are now growing freely, and will be benefited by the application of stimulants. The majority of ferns like shade and moisture, but they should not be syringed overhead if there is any fear of the sun catching them while the moisture is hanging upon them, otherwise scorching will occur. Adiantum Farleyense and the various gymnogrammas do not need such heavy shade, and while delighting in a moist atmosphere, are very impatient of being syringed. From March to October Adiantum cuneatum and A. gracillimum succeed admirably in vineries, and plants grown in such houses are generally more serviceable for decorative purposes than are those grown in the fernery proper. Plants of Plumeria alba which have been kept dry since they shed their leaves, and are now commencing new growth, should be afforded water, repotting those requiring it and top-dressing others.—J. TUNNINGTON, *Ripley Castle Gardens, Yorks.*

KITCHEN GARDEN.

THE welcome showers of last week have been of great benefit to all vegetable crops, the fall of rain on May 5 being the largest we have had during the present year, about ·48 in. being registered, so that the ground now is fairly moist. With the land in this condition and the weather warm growth will be very rapid, particularly of small weeds, the hoe should therefore be kept going amongst seedling plants, such as onions, carrots, parsnips, turnips, &c. The thinning of these must also receive attention, for to allow the plants to become overcrowded before they are thinned is a great mistake. It is not necessary that they have the full distance given them at the first thinning, as, if allowed to remain double the ultimate thickness, every other plant may be drawn for use later on. Where the onion fly is troublesome dust the plants with soot early in the morning when the dew is on them, this will make them distasteful to the flies. Cauliflowers for autumn should now be planted out, choosing such varieties as Early Autumn Giant, Autumn Mammoth, Michaelmas White, &c. The distance these should be placed apart greatly depends on the quality of the ground. On good land two feet from plant to plant and three feet between the rows will be found none too much. The last sowing of broccoli seed should now be made. This should consist of such varieties as Standwell, Continuity, May Queen, Late Queen, &c. Another sowing should also be made of savoys for a late supply. We have found none to equal Perfection; it is of beautiful shape and delicate in texture. Brussels sprouts for an early supply should now be planted out, and where the ground is limited they may be allowed nine inches apart between the plants, and two of every three should be transplanted again before the leaves touch each other, finally leaving the plants twenty-seven inches apart in the row, and allowing at least thirty inches between the rows. Seakale raised from cuttings will now be forward enough for disbudding. This is an operation that should be done with care, or several more growths may push from each root. It is a good plan to remove the soil from around the sets to the depth of about two inches and rub of all growths found except one on each root, leaving the strongest. The early celery should now be put out into the trenches, and should the weather be dry at the time of planting, a little shade should be afforded till the plants have taken new roothold. Those for succession should be pricked out on a rich, light soil, that they may be lifted with balls of earth attached when required for planting out. Vegetable marrows may now be planted if protection be afforded them at night till all danger of frost is passed. Potatos that were planted about the middle of last month will now be showing through the soil, and to prevent any being caught by late frosts, a little earth may be drawn over them.

From the present time to the end of the next month is the worst period for the growth of peas, for often those sown at this date are just coming into bloom when the hot dry weather of July visits us, and are on that account very subject to the attack of fly. It is well, therefore, to make sowings once a week from this date until the end of June, as by doing so some are sure to escape this troublesome pest. Late Queen, Autocrat, and Carter's Michaelmas are all good kinds of medium growth. Those who require taller ones will find Duke of Albany a good free sort. Runner beans may now be planted with every prospect of their escaping the frost without protection. Carrots for a late supply should also be sown, choosing such varieties as Intermediate. Spinach is often a troublesome crop to grow in summer, and for this reason the seed should now be sown in a cool shady place, and abundance of water afforded in dry weather.—H. C. PRINSEP, *Buxted Park Gardens.*

FRUITS UNDER GLASS.

YOUNG pot figs, raised from cuttings of the ripened wood last autumn or early in this year, will now require shifting into eight-inch pots, and those, a year older, which are expected to begin fruiting next year should be transferred into ten-inch or twelve-inch pots as soon as possible, so that they may have time to fill the pots with roots before they go to rest. Firm potting is essential, and the soil should be of a richer nature than that recommended for figs planted out in borders, still it should be of a similar porous character, that most suitable being a mixture of fibrous loam, broken mortar rubbish (that from "hair plaster" being the best), and some one-quarter-inch bones, the latter if of good quality may be freely used, and will act as an excellent fertiliser. As the fig enjoys plenty of water in the growing season, it is essential that good drainage, carefully placed in the pots, be provided. After potting, plunge the pots in a moderately warm hotbed, and afford a light shade to the glass for a few days, until they have recovered. The older pot trees, which have already ripened a crop, will have the second crop fairly advanced, and will, in many cases, require a good rich top-dressing, which will not only assist the fruits to swell, but will also help the trees to make good wood for next year. It is a mistake to take a third crop from pot trees, and after the second has ripened, it only then remains to thoroughly ripen up the wood. In the meanwhile prevent any overcrowding of shoots, a limited number of good growths to each tree being better than a crowd of weaker ones. Ply the syringe on every favourable occasion to keep down spider, the great enemy of indoor fig trees. As the fruits in the cherry house begin to show colour, syringing for the time should be discontinued, as it tends to make the fruit crack. If thought necessary to hasten the ripening, the night temperature may be slightly advanced, but it is not safe to go much above 55 degrees at night by fire heat, unless the outside temperature is high; some air should be left on the house at all times, and increased early in the morning. Any grass shoots on orchard-house trees should either be kept close pinched or rubbed off entirely, the latter method only being recommended when such shoots are not in close proximity to bunches of fruits. Pot orchard-house trees, such as plums, apricots, &c., will now derive great benefit from a rich top-dressing, and a similar one should be again applied after stoning is complete. Cool treatment suits these subjects best, and the great things to avoid are sudden rises of temperature, dryness at the root, attacks from insect pests, and sharp draughts when the wind is in the east.

The house of fruiting pines should be closed early with plenty of sun-heat to hasten the advancing fruits. The temperature may be allowed to rise freely at closing time without any fear of injury, provided a very humid atmosphere is created by syringing freely among the plants and also thoroughly damping all available surfaces. Examine the plants frequently, and give weak doses of guano water to all that are swelling their fruits whenever they require watering. The most forward young stocks may now, if well-rooted, be placed in their fruiting pots; this should never be neglected, as starved plants never do well. Keep down all sucker growth on older plants except sufficient to provide stocks, and the aim in this case should be to leave one strong sucker and no more to a plant, and to remove this when it has grown to a sufficient size for propagating purposes. I do not consider it good practice for general adoption to leave the suckers on till they become almost as big as the parent, and certainly it is not kind to the latter.

It is possible in fine autumns to pick good dishes of strawberries from plants which were forced for early supplies. My favourite strawberry, Vicomtesse Hericart de Thury, is certainly the best in existence for this double purpose, and the plants should be well looked after and protected for a week or two after being turned out of the forcing house; then, when the weather is settled and all traces of spider have been removed from the leaves, plant them out in a rich and sunny border and look well after them in the matter of watering. Perhaps the best method is to plant rather thickly in blocks that may be enclosed later on within a frame and covered with lights, which will render the grower independent to a certain extent of the weather we may have when the second crop of fruit is ripening.—J. C. TALLACK, *Livermere Park Gardens.*

TOO-MUCH-ALIKE CHRYSANTHEMUMS.

THE official report of the Classification Committee of the National Chrysanthemum Society is published with the schedule of prizes for the current year, and the following reference to the question of too-much-alike varieties will be of interest to the general body of cultivators for competitive purposes.

At a meeting of the committee held on January 31 a discussion ensued as to the expediency of grouping together varieties of incurved chrysanthemums which might be regarded as too much alike. Eventually it was unanimously resolved that it be a recommendation to the Executive Committee that the following paragraph be inserted in the schedule of prizes:—

"Experience having shown that several chrysanthemums classed as distinct are much alike when staged for competition, it has been found advisable to lessen the risk of duplicates being shown in classes for cut blooms, in which they are required to be distinct; therefore, in the cases of varieties that at certain stages of development closely resemble each other, the blooms exhibited must, in classes for distinct varieties, be sufficiently diverse, so as to be readily distinguished by the judges."

The foregoing report was laid before a meeting of the Executive Committee, held on February 21, when the following resolution was passed:—

"That the report of the Classification Committee be referred back to that body, with the request that they will prepare a list of too-much-alike varieties, for publication with the schedule of prizes."

In accordance with the foregoing resolution, the committee met on April 4; Mr. George Gordon, the elected chairman for the year, presiding, when the following was adopted for publication in the annual report for the present year:—

The following is a list of varieties of chrysanthemums, either classed as synonymous, or as too much alike, or which at times so nearly approach each other in general appearance that they must not be shown on the same stand—

Incurved Varieties.

C. H. Curtis
Major Bonaffon

Duchess of Fife
Mrs. Airdrie

Empress of India
Lady H. St. Clair
Mrs. Cunningham
Snowball
White Queen

Golden Empress of India
Bruce Findlay

Golden George Glenny
Mrs. Dixon
Mrs. C. H. Glover

John Doughty
Mrs. Robert Mudie
Bronze Queen of England

John Lambert
Golden Queen of England
Emily Dale
Emily Dale Improved

John Salter
Mr. Howe

Lady Dorothy
Charles Gibson

Lord Alcester
Princess Imperial

Miss M. A. Haggas
Richard Parker

Mrs. Heale
White Princess

Mrs. George Rundle
Mrs. George Parnell

Princess of Teck
Charles Shoesmith
Christmas Number

Princess of Wales
Beauty of St. John's Wood
Mrs. Heale

Queen of England
Blush Queen of England

Japanese Varieties.

G. J. Warren
Yellow Madame Carnot

Mrs. C. Blick
Mrs. Richard Jones

Pride of Madford
Beauty of Teignmouth

Sunflower
Swanley Yellow

W. Slowgrove
Improved W. H. Lincoln
T. Selwood

Hairy Varieties.

Enfant des deux Mondes
White Louis Boehmer

Hairy Wonder
R. M. Gray

Esau
Princess Ena

The attention of exhibitors is particularly called to the foregoing lists of too-much-alike varieties bracketed together, which should be carefully examined previous to staging blooms for competition.

Androsaces.—Of the various androsaces now in flower there is none so effective as A. sarmentosa. Given a sunny position on the rockery, in sandy loam, it will flourish and produce its runners freely; these should be pegged down and covered with soil to increase stock. The flowers are rose in colour with white centres, born on slender stems. Another diminutive species now flowering is A. cylindrica, with white flowers and yellow centres. This prefers a damp shady position, and to be planted in peat and loam. A. pyrenaica has been in flower since February; it delights in a sunny position, among the fissures of rocks and stones, planted in soil consisting of sandy peat and loam. The plants are literally covered with their pure white flowers, borne on stems scarcely a quarter of an inch high. All the androsaces are charming plants for the rockery, when grown under proper conditions, and in the majority of cases are easily increased by cuttings or seeds.—E. SCAPLEHORN, *Woking.*

THE BEST GUIDE to the garden for the whole year is the "Gardening Year Book," Price 1s., containing practical articles on the cultivation of Flowers, Fruit, Vegetables, &c. "Gardeners Magazine" Office, 4, Ave Maria Lane, London.—[ADVT.]

EXHIBITIONS AND MEETINGS.

ROYAL HORTICULTURAL SOCIETY, May 10.

THERE was a much smaller gathering and display on this date than at the previous fortnightly meeting. Many exhibitors were, no doubt, saving themselves for the coming Temple Show, and a few for the Royal Botanic Society's Exhibition. A great many visitors were doubtless kept away by reason of the Drawing Room held the same day. It was by no means a poor show, however, and there were several novelties.

FLORAL COMMITTEE.

Most of the exhibits came before this body, and they consisted chiefly of roses, tulips, hardy flowers and shrubs, crotons, and azaleas. There were few novelties before this committee, and auriculas and azaleas almost monopolised the awards.

Roses in pots, as well as a goodly number of cut blooms, were shown in fine condition by Messrs. W. Paul and Son, Waltham Cross, who were awarded a silver Flora medal for their two groups. Some of the best-flowered specimens were of such charming varieties as Marchioness of Lorne, Jeannie Dickson, Gustave Piganeau, Enchantress, Gloire Lyonnaise, La France, Madame Fanny de Forrest, Victor Verdier, Triomphe de Caen, Caroline Testout, and Prince Camille de Rohan; the cut blooms were chiefly Maréchal Niel and Magna Charta; Medea. Corinna, Empress Alexandra of Russia, Queen Mab, and Zephyr, all Messrs. Paul's introduction; La France, Dr. Andre, Jules Finger, Madame Lambard, and Viscountess Folkestone. From Messrs. J. Veitch and Sons, Chelsea, came a large basket of the sweet, rose-flowered Daphne Cneorum, Anemone nemorosa flore-pleno, Hydrangea japonica Mariesi, a form with huge bracts; Rubus deliciosus, a handsome bramble, and the yellow-foliaged form of Sambucus racemosa.

Messrs. Barr and Son, Covent Garden, staged a most interesting group of hardy plants and flowers. Primulas were well represented, so also were saxifragas, aubrietias, candytufts, pansies, violas, and terrestrial orchids, the latter including Orchis provincialis, O. papilionacea, O. mascula, O. tenthredinifera, O. italica, and O. bombilifera, all very pretty and interesting. Spanish irises were very beautiful. Tulips were much admired, and represented by fine bunches of good flowers; May Queen, Glow, Queen of Roses, Hecla, crimson; The Sultan, blackish marone; Early Dawn, bright rose; and Scarlet Beauty were among the most distinct of the Darwin tulips. Tulipa saxatilis, rose and yellow, is a very distinct species, as is T. Batalini, pale yellow. Picotee was well represented, as also were the parrot tulips, a set of remarkable shape and gorgeous colours. The Messrs. Barr gained a silver-gilt Flora medal, the highest award of the day, for their extensive display. Messrs. J. James and Son, Farnham Royal, Slough, showed a few more of their cineraria hybrids; the plants were the result of crossing the progeny of Cineraria cruenta, crossed with garden forms, with Cineraria lanata. The plants were dwarf, and many showed very distinctly their lanata parentage by the woolly leaves and stems; one or two retained some of the characteristics of the garden form, all were dwarf, and their colours varied from pure white to deep blue and white. Mr. A. Tulett, Crocken Hill, Swanley, staged a basket of plants of Pelargonium A. Tulett, a bright semi-double sport from the well-known F. V. Raspail.

From Messrs. W. Balchin and Sons, Hassocks, Hove, and Brighton, showed some very interesting plants. There was a small group of Browallia elatior, covered with rich blue flowers, all well grown in small pots; Boronia serrulata, clothed in rosy blooms; Erica perspicua nana, a mass of blooms; and some tiny plants of Boronia heterophylla, carrying plenty of its scented flowers. Some handsome azaleas came from Mr. Charles Turner, Slough: Marie Vervaene, white and scarlet; Mons. C. Vuyleteke, scarlet; Louise Cuvelier, creamy white; Ami Charles Vermeire, scarlet; and Dryade, white, semi-double, were conspicuously good. Mr. Turner also sent a pretty plant of the polyantha rose Thalia, a white-flowered Rambler; and also a few flowering specimens of the Princess May form of Souvenir de la Malmaison carnations. Messrs. W. Cutbush and Son, Highgate, showed an extensive group of bright plants, including Erica ventricosa minor, E. hyemalis alba, E. Cavendishi, mollis and Indian azaleas, Hydrangea Thomas Hogg, Boronia heterophylla, and some tall wistarias, these being arranged amid elegant-foliaged Japanese maples, palms and ferns; a silver Banksian medal was awarded.

A magnificent lot of cut roses came from Mr. George Mount, Exotic and Rose Nurseries, Canterbury; those cut with long stems again excited the wonder of growers and visitors by reason of the wonderful strength of the growth and foliage; every bloom was perfect, with full fat petals of good colour, and fragrant. Mrs. John Laing, Caroline Testout, Catherine Mermet, Captain Hayward, General Jacqueminot, Ulrich Brunner, La France, The Bride, and Madame Montet were all wonderfully fine, and the varieties most freely staged; Mr. Mount was awarded a silver Flora medal for his fragrant exhibit. Messrs. F. Miller and Co., Fulham Road, S.W., showed some very fair East Lothian stocks; the white forms were good and sweetly fragrant; the edging of market boxes of pyrethrum was not admired. Messrs. Paul and Son, Cheshunt, showed some pretty sprays of a new double white cherry, and also of Cerasus Watereri. There were pairs of dwarf phloxes suitable for rockery decoration, candytufts, the pretty Arenaria balearica, and Primula rosea grandiflora in the group of hardy plants for which the firm gained a silver Banksian medal.

Crotons in great variety came from Mr. H. B. May, Edmonton, and were represented by neat specimens in forty-eight sized pots; Morti, Van Oerstersi, Thomsoni, Goldi, Flambeau, Reidi, Golden Ring, Ker's Sunshine, Aigburth Gem, Gordoni, and Earl of Derby were notable and highly-coloured examples, and these with all the other sorts shown were finely grown plants, though not large; silver Banksian medal. Mr. D. Storrie, St. Madge's Cottage, Glencarse, showed a large number of splendidly grown and fragrant border auriculas; these, if they did not all conform to the florists' standard, were greatly admired for their freedom, beauty, and fragrance; the majority were yellow and shades of yellow; none of the plants had ever been given shelter, and all were the result of fifteen years of generations of seedlings from one original plant. Mr. James Douglas, Great Gearies, sent several handsome auriculas, all alpine forms; Perfection, gold and crimson; Clytie, marone and yellow; J. Gilbert, purple and white; and Dean Hole, crimson and yellow, were all very fine. Mr. B. Bennett, Cheverells Park, Dunstable, sent a large branched flowering-spike of Dracæna indivisa. Messrs. J. Cheal and Son, Crawley, staged a group of bunches of cut sprays of the various hardy flowering shrubs in season; Cytisus præcox was among the most beautiful of all; violas were choice and good for the early date; Lord Elcho, yellow; Iona, blue and violet; Pencaitland, white; Skylark, blue edged; Duchess of Sutherland, rosy mauve; A. J. Rowberry, yellow; and Bridesmaid, pale lemon, [illegible]y fragrant, fresh, and bright.

ORCHID COMMITTEE.

A large and handsome collection of orchids was tastefully staged by Messrs. J. Veitch and Sons, Chelsea; there were large examples of Cymbidium Lowianum, Oncidium ampliatum majus, Odontoglossum Halli, Vanda tricolor, and Epidendrum Wallisi as background, with such gems as Lælia Latona, Miltonia Warscewiczi, Masdevallia Veitchi, Cypripedium caudatum, Rodriguezia pubescens, Oncidium spilopterum, Lælia-cattleya Ascania, and Cattleya intermedia alba, the latter a fine plant with four lovely and pure-white flowers, a specimen of great worth. A silver-gilt Flora medal was awarded. Messrs. Hugh Low and Co., Bush Hill Park, Enfield, staged some handsome varieties of Odontoglossum crispum, some rose-tinted and others finely spotted; Cattleya Mendeli in fine form was shown in company with Lælia purpurata, Cattleya Skinneri, &c. C. intermedia concolor attracted attention among orchidists, while the ladies greatly admired the arching spikes of Oncidium Marshallianum; silver Banksian medal.

A charming lot of odontoglossums and miltonias came from Messrs. L. Linden and Co., Moortebeek, Brussels; there were some lovely white forms of O. crispum, and a splendid branched spike of O. Pescatorei, carrying sixty-four flowers. The forms of Miltonia vexillaria were equally handsome, and all gave evidence of remarkably high cultivation. Some thirty spikes of O. crispum were staged. Cattleya intermedia, Fowler's variety, with a creamy lip and purple tip, was shown by Mr. J. Davis, gardener to J. Gurney Fowler, Esq., Glebelands, South Woodford. Mr. Stafford, gardener to F. Hardy, Esq., Tyntesfield, Ashton-on-Mersey, sent some beautiful forms of Lælia purpurata and two blooms of the pure white sobralia; Sophro-cattleya George Hardy, obtained by crossing Sophronitis grandiflora and Cattleya Acklandiæ, was the gem from Tyntesfield; Cattleya Lawre-Mossiæ and Cypripedium Goweri also came from this collection. Mr. Bond, gardener to C. L. N. Ingram, sent Lælio-cattleya Fascinator, a magnificent hybrid between L. purpurata and C. Schroderæ; this has a huge purple apex to a yellow-throated lip. Mr. J. Robson, Bowdon, Cheshire, sent a form of Odontoglossum Rochfordianum. Mr. Johnson, gardener to T. Statter, Esq., Stand Hall, Manchester, gained a cultural commendation for Cypripedium macrochilum giganteum with two big flowers.

Mr. W. Cobb, Tunbridge Wells, gained a first-class certificate for the Dulcote var. of Lælio-cattleya Hippolyta, a very brilliant form. A good form of Cypripedium hirsutissimum came from Mr. Harris, gardener to P. Crowley, Esq., Croydon. Mr. F. Thorne, gardener to Major Joicey, Sunningdale Park, showed a fine example of Anguloa Ruckeri atrosanguineum, a plant with six large blooms to one growth; Mr. Thorne also sent Eriopsis rutidobulbon, with a spike of eighteen flowers; this is a rare orchid, and one not wanting in beauty. Some very handsome forms of Odontoglossum crispum were shown by Mr. Barrell, gardener to Welbore Ellis, Esq., Dorking; the spikes were strong and the flowers large, substantial, and in many cases prettily spotted; two Miltonias, one with nine and the other with eleven spikes, were both very handsome specimens of good varieties of the well-known M. vexillaria. Messrs. J. Veitch and Sons, Chelsea, staged Spathoglottis aureo-Viellardi, a hybrid between the two species its name indicates; it has yellowish flowers with rosy-red spottings; this firm also sent Lælio-cattleya Wellsiana albida. Vanda teres candida from Messrs. H. Low and Co. was very beautiful, its sepals and petals being pure white; this firm also sent a natural hybrid dendrobium, no doubt a cross between D. Boxalli and D. Hildebrandi.

FRUIT AND VEGETABLE COMMITTEE.

A large collection of radishes grown in frames was brought up from Chiswick by Mr. S. T. Wright. These had been on trial there, and now came before the committee. Five varieties gained awards of merit, and these are referred to in another column. The collection was of great interest to those who have to cultivate early radishes. Mr. James Hudson, gardener to Messrs. de Rothschild, sent sixteen handsome fruits of Rivers' Cardinal Nectarine, all gathered from pot trees started December 2; the fruits were gathered on May 2. Mr. John Ryder, gardener to the Dowager Countess of Limerick, St. Albans, sent some splendid Alexandra peaches for which a cultural commendation was awarded. Mr. Taylor, gardener to C. Bayer, Esq., Tewkesbury Lodge, Forest Hill, showed Waterloo peaches taken from trees in pots started on New Year's Day.

By far the most attractive display before this committee consisted of three boxes of Royal Sovereign strawberries, staged by Mr. G. Norman, gardener to the Marquis of Salisbury, Hatfield; the fruits were of enormous size, and yet of very fine shape; one hundred and twenty eight magnificent fruits were staged, and Mr. Norman well deserved the silver Knightian medal awarded; the fruits averaged an ounce and a half in weight.

Mr. Banten, Buscot Park Gardens, sent a new melon that, however, failed to gain an award; he also sent two good dishes of Royal Sovereign strawberries.

From the Syon House Gardens, Brentford, Mr. G. Wythes showed a seedling lettuce of great merit and earliness; also dishes of Wythes' Improved Mohawk, Syon House Mohawk, Ne Plus Ultra, Sutton No. 66, and Early Forcing French beans.

The first prize for the best-flavoured apple was awarded to Mr. R. Bullock, gardener to C. P. Serrocold, Esq., Maidenhead, for Hereford Pearmain; Mr. Woodward, Barham Court Gardens, second with Calville Rouge. For the best pear a second prize was awarded to Mr. C. Herrin, Dropmore, for Beurre Bretonneau in first-rate condition.

ROYAL BOTANIC SOCIETY.

NOTWITHSTANDING the frequent suggestions of rain made by masses of black clouds alternating with scalding gleams of sunshine, no rain fell on the 11th inst. to mar the summer show of the Royal Botanic Society. There was, however, a boisterous north-west wind that made the weather somewhat unpleasant outside the large show tent and corridor. The display was a fairly good one, and made up chiefly of trade exhibits. It is years since vegetables in any quantity were seen at Regent's Park, consequently Mr. Empson's exhibit was most welcome.

COMPETITIVE EXHIBITS.

For a group of orchids Mr. Cragg, gardener to W. Walker, Esq., Winchmore Hill, secured first prize with a showy lot of odontoglossums, interspersed with Cattleya Mendeli, the fragrant C. citrina, and arching spikes of Oncidium Marshallianum. Mr. Cragg was also first for six orchids. Mr. G. Kelf, gardener to Mrs. Abbott, Regent's Park, was first for six specimen palms, showing big specimens of Areca lutescens, Phœnix reclinata, Chamærops humilis, and Latania borbonica. Mr. Empson was first for a pair of dracænas, one being a large D. Sanderiana; he also was first for six foliage plants with small crotons and dracænas. The first prize for ten specimen roses was secured by Messrs. G. Jackson and Son, Woking, with large examples of Crimson Rambler, Madame Lacharme, Senateur Vaisse, La France, Celine Forestier, and others; Mr. W. Rumsey, second. Mr. G. Mount, Canterbury, was first for twenty-four roses, his set including fine blooms of A. K. Williams, Ulrich Brunner, General Jacqueminot, La France, and Marie Finger; Mr. W. Rumsey, second.

NON COMPETITIVE DISPLAYS.

A large and handsome exhibit was contributed by Messrs. J. Laing and Sons, Forest Hill, and it occupied one of the central sloping banks. This was a gorgeous display of brilliant tuberous begonias, and very handsome gloxinias, graceful spikes of odontoglossums, and lovely cattleyas, intermixed with crotons, bold caladiums, and elegant palms, chiefly cocoses; the whole was bedded in fern and edged with isolepis, and was in every way effective and tasteful. In addition, the Forest Hill firm staged some charming rose bouquets, baskets of Spanish irises, richardias and lily of the valley.

Messrs. W. Paul and Son, Waltham Cross, put up a fine bank of pot roses, fronted with boxes of cut blooms; among the specimens were tall pillars of Caroline Testout, Duke of York, Violette Bouyer, Alphonse Soupert, Jeanne Dickson, Victor Verdier, and Enchantress, all freely flowered and very handsome; in front of the boxes of cut blooms containing flowers of the leading Waltham Cross introductions, was a line of maidenhair ferns that added greatly to the effectiveness of the exhibit.

A most brilliant display of tulips came from Messrs. Barr and Son, Covent Garden. The kinds most admired were the handsome Darwin, or breeder tulips, Tulipa retroflexia, golden yellow, and the extravagant parrot tulips. Large bunches of Cytisus præcox and C. filipes flanked the group, but a background was sadly needed. A charming exhibit came from Mr. H. B. May, Edmonton; this consisted of pretty plants of the Crimson Rambler rose, in 48-sized pots, all freely flowered, and alternated with Spiræa astilboides crowned with snowy plumes. Acer Negundo variegata formed an effective background, while pterises and maiden-hair ferns made a fine groundwork. A few plants of Hydrangea Thomas Hogg, with nice heads, were also shown, and every plant in the group could be seen standing clear of its neighbour. A group of small plants of Japanese maples was staged by Messrs. J. Waterer and Sons (Limited), Bagshot; the most effective varieties were A. japonicum aureum, A. palmatum septemlobum elegans, A. palmatum sanguineum, A. p. digitatum, A. p. atropurpureum, and A. p. dissectum variegatum. The Cardinal nectarine, one of Messrs. F. Rivers and Son's recent introductions, was finely staged by the firm, and represented by well-grown standard trees carrying a splendid lot of handsome fruits. This fine nectarine ripens its fruits ten days earlier than Early Rivers. Sixteen trees were staged, and two boxes of fruits. Mr. W. Rumsey, Joynings Nursery, Waltham Cross, put up a large group of cut roses and flowering specimens in pots. A tall pillar of Claire Jacquier, and the new H. P. Mrs. Rumsey, were greatly admired for their plentiful blooms. The boxes of Niphetos roses contained a large number of fresh, clean blooms.

Mr. G. Mount, Canterbury, transferred his grand exhibit of roses from the Drill Hall to Regent's Park, and some of the blooms were finer than on the previous day. One flower was fully six inches across, and had leaves attached to the stem measuring nine inches in length. About a gross of excellent blooms were staged. Messrs. J. Peed and Sons showed two boxes of bloom of gloxinias, chiefly spotted varieties of great merit; also a box of excellent single begonia blooms. Messrs. W. Cutbush and Son, Highgate, put up a fine lot of Malmaison carnations, together with heaths, azaleas, chiefly gorgeous mollis forms, boronias, wistarias, and Otaheite oranges, arranging these tastefully with palms, dracænas, ferns, isolepis, and elegant Japanese maples. Messrs. A. Young and Co., Stevenage, arranged a collection of early-flowering alpines and other hardy flowers on a sloping bank amid cork, so as to give the appearance of a rockery; the liliums, polyanthuses, violas, irises, primulas, and alyssums proved interesting. The new King of Denmark pelargonium was also shown, it is a semi-double salmon form. Mr. A. Smith, Downes, High Wycombe, sent five boxes of blooms of Maréchal Niel roses.

Mr. W. J. Empson, gardener to Mrs. Wingfield, Ampthill, Beds, had an extensive display of fruit and vegetables. Bananas, Royal Sovereign strawberries, Duke of York tomatos, Holborn Model leeks, Ailsa Craig onions, Early Forcing French bean, mushrooms, asparagus, and new and old potatos were all very good. There were pots of Carter's Forcing pea, and also freely-fruited specimens of climbing French beans. Radishes were a great feature of the group, and comprised bunches of long, round, and olive-shaped varieties in white, red, scarlet, and yellow, with one or two piebald ones; Delicatesse, Long Scarlet, London Long Red, and Carters' White Naples were good, and appeared very crisp. Mr. T. S. Ware, Tottenham, had an interesting collection of hardy plants staged in pairs; there were good examples of Primula Sieboldi, Dodecatheon splendidum, Ranunculus speciosus, Androsace lactea, Ranunculus parnassifolius, Iris lupina, Darlingtonia californica (in flower), Orchis pallens, O. militaris, O. mascula, O. fusca, Epimedium alpinum, and Ramondia pyrenaica. Messrs. J. Peed and Son, Norwood, put up a noble group of well-developed and highly-coloured caladiums, all of great beauty; John Peed, Duchesse de Mortmart, L'Insolite, Lord Moseley, Rose Laing, Louis van Houtte, and Puvis de Chevannes were notable specimens. The same firm staged a finely-grown collection of dracænas, this including such excellent sorts as Prince Marouk Bey, Excellent, Goldiana, Alexandra Laing, Frederick, and Pendula.

One of the most extensive displays came from Messrs. B. S. Williams and Son, Upper Holloway; it consisted of a large central bank of choice orchids, flanked by anthuriums and clivias. Lælia purpurata, Oncidium concolor, Cattleya Mendeli, Odontoglossum crispum, O. Ruckerianum, O. cirrhosum, and O. luteo purpureum were the most conspicuous orchids, besides Vanda suavis. The clivias were very bright, and showed that these plants are as readily retarded as advanced. There were grand trusses of Ambroise Verschaffelt, atrosanguinea, Lindeni, and Surprise. Ferns in variety, heaths, lilacs in pots, a few cannas, and number of excellent mollis azaleas were also shown, and helped to make up a large and brilliant display. Mr. Prewett, Bayswater Road, had a light and tasteful decoration in yellow Spanish irises and poet's narcissi, arranged in silvered vessels. Messrs. B. S. Williams and Son brought a grand lot of floral arrangements from their Piccadilly branch. The basket of La France and Ulrich Brunner roses was especially fine, while the basket of odontoglossums was almost as good; a mirror frame of white stocks, a bouquet of scarlet pelargoniums and anthurium spathes, and one of roses and lily of the valley completed an excellent and beautiful display. Mr. Keef, gardener to Mrs. Abbott, Regent's Park, staged a bank of well-grown palms and Lilium Harrisi, with a border of gloxinias, small caladiums, crotons, ferns, &c., before them. Azaleas were extensively shown by Mr. Charles Turner, Slough, who staged about forty small and medium-sized specimens. Louise Cuvelier, white; President van Imschoot, crimson-scarlet; La Printemps, scarlet; Dryade, snow-white; Hexe, carmine; Duc de Nassau, rose; and Mrs. Turner, pink, were among the best.

MEDALS.

Silver-gilt Flora Medals were awarded to Messrs. B. S. Williams and Son, Messrs. J. Laing and Sons, Messrs. W. Paul and Son, Mr. Charles Turner, Messrs. J. Peed and Son, and Messrs. T. Rivers and Son.

Large Silver Medals to Mr. H. B. May, Messrs. W. Cutbush and Sons, Mr. Empson, gardener to Mrs. Wingfield.

Silver Medals to Messrs. Barr and Son, Mr. T. S. Ware, Mr. G. Mount, Messrs. B. S. Williams and Son (for florists' arrangements), and Mr. Keef, gardener to Mrs. Abbott, Regent's Park.

Bronze Medals to Mr. A. Young, Messrs. J. Waterer and Sons, Messrs. J. Laing and Sons (for bouquets), Mr. Prewett, and Messrs. Peed and Sons (for cut blooms).

NATIONAL TULIP SOCIETY, May 11.

ON the above date, and in conjunction with the Royal Botanic Society's summer show, the National Tulip Society held its fourth annual southern exhibition at Regent's Park. The display was made in the corridor, and here it was not shaded from the flashes of brilliant sunshine that occurred during the day. The exhibition was not extensive, but there was a very fair, and sometimes very keen, competition in the various classes. There were some wonderfully fine flowers, and also some very poor ones, so on the whole it was an average display.

The chief award for a dozen dissimilar rectified tulips was won by Mr. Alfred Chater, Cambridge, with some fine blooms; the varieties were Duchess of Sutherland, Sarah Headley (feathered), Guido, Orion, Sarah Headley, Samuel Barlow, Glory of Stapleford, Mrs. Jackson, Richard Headley, Modesty, Masterpiece (feathered), and John Linton; Mr. A. D. Hall, Wye, Kent, second, his finest flowers being Comte de Vergennes, Sir Joseph Paxton, Bessie, Annie McGregor, and Richard Yates; the third prize was secured by Mr. C. W. Needham, Royton, Lancs; and the fourth by Messrs. Barr and Sons, Covent Garden. Mr. J. W. Bentley, Middleton, Lancs, secured the premier award for six dissimilar rectified tulips with Lord Stanley, Annie McGregor, Adonis, Comte de Vergennes, William Wilson, and Bessie; Mr. A. Chater second, with Dr. Hutchison, Sarah Headley (feathered), Modesty, Duchess of Sutherland, Masterpiece, and J. Linton; Mr. C. W. Needham was equal second, with nice flowers of Dr. Hardy, Sarah, Duchess of Sutherland, Aglaia, Modesty, and Masterpiece.

Mr. Bentley scored for three flamed tulips with bright blooms of Lord Stanley, Mabel, and King of the Universe; Mr. Needham, second, with Mrs. Jackson, the popular Mabel, and Samuel Barlow; Mr. A. Chater, third. The Samuel Barlow prize for the best pair of rectified tulips, one feathered and one flamed, was won by Mr. J. W. Bentley, with good flowers of Duke of Devonshire and Sir Joseph Paxton; Mr. Hall came second, with Sir J. Paxton and Comte de Vergennes. For six dissimilar breeder tulips, two roses, two byblœmens, and two bizarres, the chief award was secured by Mr. A. D. Hall, who showed Glory of Stakehill, Mabel, John Heap, Lloyd's 200, Annie McGregor, and Excelsior; Messrs Barr and Sons, second; and Mr. J. W. Bentley, third. Mr. J. W. Bentley took leading honours for three breeder tulips, one of each class, with neat blooms of Mabel, Storer's Seedling, and Glory of Stakehill; Mr. C. W. Needham, second, with Annie McGregor, Adonis, and Richard Yates.

The premier breeder tulip in the show was a pretty bloom of the bizarre Goldfinder, shown by Messrs. Barr and Sons. The best feathered bloom was Industry, scarlet, over a creamy ground, shown by Messrs. Barr and Sons. Mr. A. Chater had the best flamed bloom in the show in his splendid Samuel Barlow shown in his first prize set of twelve tulips.

Mr. C. W. Needham arranged an extensive collection of tulips, showing either breeder or rectified forms of twenty-five varieties; Chancellor, Dr. Hardy, Mabel, Samuel Barlow, Talisman, Modesty, Lloyd's Seedling, and Storer's Seedling were among the finest examples. Messrs. Barr and Son, Covent Garden, staged four large boxes of florists' tulips, some in rectified and some in breeder form. Friar Tuck, Talisman, Samuel Barlow, Colbert, Sir Joseph Paxton, Aglaia, Alice, Dr. Hardy, and Amazon, were all well represented. One box contained good blooms of the breeder forms: Mabel, rose; James Wild, bizarre; Miss Hardy, byblœmen; Goldfinder, bizarre; Lord Derby, rose; William Lee, bizarre; and Modesty, rose. The Messrs. Barr were awarded a gold medal for this display, while their group of Darwin and other May-flowering tulips, staged in large bunches in the big tent, and forming part of their display in connection with the R.B.S., was awarded a first prize as the best collection of May-flowering decorative tulips in the show.

As there was no competition in the class for 100 blooms of English florists' tulips, the silver cup offered as a first prize was not awarded, though Mr. Needham's exhibit fulfilled the schedule requirements.

SCOTTISH HORTICULTURAL ASSOCIATION.

THIS association recently held another very successful and crowded meeting in the society's rooms. Among the exhibits on the table were three beautiful blooms of the chrysanthemum W. H. Lincoln, sent from Mr. P. Hunt, Coltbridge Hall, and some very choice narcissus from Mr. J. Alexander, Revesby Abbey, Boston, who had promised a paper on bulb-growing in Lincolnshire. Among the narcissus were fine examples of Sir Watkin, Golden Spur, Incomparabilis, Poeticus, single and double; a very pure paper-white semi-double form of N. orientalis, Bicolor grandis, &c. Mr. Todd, the president, also exhibited a beautiful group of narcissus and irises, arranged with smilax and other foliage.

In the absence of Mr. Alexander, Mr. R. L. Laird, the secretary of the society, read his excellent paper. With a few sentences on the enormous importations from the Scilly Islands, Guernsey, &c.—said at times to total up to two hundred tons of flowers in a day [?]—and the extreme usefulness and durability of daffodils for decorative purposes, Mr. Alexander proceeded to give a brief [illegible] of the culture of two of our best English growers, Mr. T. Kime, Mareham-le-Fen, Boston, and Messrs. White and Sons, near Spalding, some twenty miles distant. The second has the best, or at least the deepest soil, though that of Mr. Kime has been greatly improved by the addition of spent tan and other refuse. The Boston grower plants chiefly in rows from nine to fourteen inches apart; the other in beds four feet wide—the bulbs from four to six inches apart each way, and uses soot and bone dust as top dressings. Immense quantities are grown alike for selling as hardy cut flowers in the spring and for forcing, which begins early in November. Block succeeds block until the latest crops come in from the open ground in April and May. All the finest varieties are grown in quantity, such as Sir Watkin, Golden Spur, and Princess, while Codlins and Cream and other old favourites are not forgotten. It was gratifying to hear from Mr. Alexander that some of the most successful growers were labourers and small holders, some of whom were said to have made as much as £20 of their bulbs.

Among other pleasing features of the meeting was the high testimony borne by Edinburgh experts in flower culture, sale or use, to the high quality of the Lincolnshire and Linton bulbs. None better entered the Waverley Market than France, the Scilly Isles, Holland, nor anywhere else. After a few words from Mr. D. T. Fish, strongly advocating an immediate extension of this promising home industry, Mr. Alexander Mackenzie, of the Warriston Nurseries, proposed a vote of thanks to Mr. Alexander for his paper, which was carried unanimously. Mr. Hay was then elected a life member of the association.

Mr. D. P. Laird, one of the judges at the Great Quinquennial Exhibition at

Ghent, and Mr. Alexander Milne, were then asked by the President to give their impressions of their visit, which proved most instructive and interesting to the members. Mr. Laird did ample justice to the full reports in the horticultural press, and then gave a vivid picture of the great exhibition, its size, and its general interest to all classes, from the King downwards. There were five hundred nurserymen in Ghent; the exhibition consisted of some twelve thousand plants and covered three acres, but of this twelve thousand there were some one thousand five hundred azaleas, and some of the plants eight feet in diameter. There were nine lots of azaleas in thirty varieties. Mr. Laird was also much impressed with the New Holland plants, the Messrs. Linden's memorial groups, the new plants, M. Louis Van Houtte's establishment, and the energy and zeal of royalty in behalf of horticulture. Mr. Alexander Milne was deeply impressed with the number and excellence of the nurseries of Ghent and Bruges. Selection rather than collection seems the chief secret of their success. One large nursery was chiefly devoted to three things—palms, Araucaria excelsa, and sweet bays. The Messrs. Sander, of St. Albans have also an enormous acreage of glass at their nurseries at Bruges. He also found a nursery with ten acres of glass managed by twenty-two men. Slow and sure seemed the characteristic of these workmen, and their hours of labour were twelve and a-half hours a days, from six a.m. to eight p.m., and all for fifteen francs (about 12s. 6d. a week) with only a quarter of an hour for breakfast, and another for dinner. Ghent is indeed an object lesson, said Mr. Milne, in more ways than one, for British horticulture and British horticulturists.—D. T. F.

AVERAGE LIFE OF THE POTATO.

In answer to Mr. J. C. Tallack I planted on March 1, 1897, side by side, ten pounds of the Duke of York and ten pounds of the Ashleaf Kidney. I gave both the same treatment and both sets were well sprouted. I found on May 10 the Ashleaf had a very promising crop under the shaws, and this was ready for use by May 20. The Duke of York was not ready before May 31. I decided to leave the two drills to see the result, and found the Ashleaf Kidney to have the heaviest crop and a better-shaped potato, but one is a kidney and the other an oval potato. Take any potato in cultivation at the present time, and give it and the Ashleaf Kidney, sent out about sixty years ago, the same treatment, and the old variety will come out the victor in quality and quantity.

Mr. Tallack says there is no comparison between the Magnum Bonum and the Syon House Prolific for weight of produce when grown under the same conditions. Up to the present time I have not found any potato to beat the Magnum Bonum. Planted beside Imperator, Up-to-Date, Champion, Lydia, Stourbridge Glory, and Reading Giant I have always found the Magnum Bonum to turn out the heaviest crop, best in quality, and free from disease. It is a variety that will grow and do well in any soil, situation, or climate, and that is a point to be considered. Potatos that will only succeed in a few places are not of the same value as those that will do well in all soils and situations. I found the Ashleaf, Gloster Kidney, and Magnum Bonum to succeed as well with me in Surrey on the chalk soil as they do here on the red soil, which is rather heavy.

Potatos will not succeed under the rough-and-ready treatment accorded in a great many places on lighter soils, such as dibbling them in. The ground should be thoroughly dug and manured during winter, and in the spring forked over; then the drills should be opened about six inches deep and two feet six inches apart, the sets being placed one foot apart; cover in with the fork, leaving a small ridge; in case of frost the ridge can, with very little trouble, be put on the potatos by means of a rake, and they will be safe for two or three weeks longer. Good potatos are often injured by bad practice.

In 1827 Mr. James Wright, gardener at Westfield, Aberdeen, planted the Scotch Pink-eye potato which is referred to in the GARDENERS' MAGAZINE of 1834. The Pink-eye is as good now as it was then, for the weight per acre averaged then from six to eight and ten tons per acre and averaged about the same with me last year; this variety has thus been in cultivation seventy-one years. [We shall be glad if Mr. Davies will tell us the number of the page of the GARDENERS' MAGAZINE for 1834 to which he refers. So far as we can find, Mr. J. Wright (p. 437) wrote, "With the Scotch Pink-eye I am not at all acquainted." Mr. Wright, however, took the same view that Mr. Davies does, that potatos do not degenerate if well cared for.—ED.] If properly treated I do not think potatos deteriorate The average weight per acre of Magnum Bonum, taking one year with another, will be about twelve tons with ordinary cultivation, but with exceptional preparation and heavy manuring they may give a return of from sixteen to twenty tons. The average yield of Ashleaf is eight to nine tons per acre of good sound potatos for eating.

The Gardens, Castle Hall. T. DAVIES.

OBITUARY.

MR. A. SIMPSON, a well-known citizen of York, died on the 4th inst. Mr. Simpson was head of the firm of Messrs. A. Simpson and Sons, Haworth Nurseries, and from small beginnings he made for himself a prominent position amongst the nurserymen of the county. He was associated with the Ancient Society of York Florists, amongst whom (as also a wide circle of acquaintances) he was very highly respected; his connection with the society extending from the year 1868, and for a great part of that time he served on the committee; he filled the office of steward for three years, and in 1894 occupied the position of chairman of the executive, the most successful year, financially, in the society's annals. Mr. Simpson was a prominent figure at the York chrysanthemum shows since they commenced, having had charge of the arrangement of the vegetable exhibits, no very light duty, as those who know the quantity of vegetables usually shown could testify. He was of robust physique and seldom under the necessity for medical treatment, so that his death was somewhat unexpected, his illness being of short duration. A paralytic seizure was the immediate cause of his decease. The interment took place at York Cemetery on the 7th inst., and was preceded by a service at St. Thomas's Church. Many of his colleagues were persent, and the chaplain of the society (Rev. H. Vyvyan) took part in the service. Mr. Simpson was in his sixty-eighth year, and leaves a widow, three sons, and two daughters.—J. L.

Orchid Sale at Clapton.—In consequence of the transfer of their head-quarters by Messrs. Hugh Low and Co., from Clapton to Bush Hill Park Nurseries, Enfield, there will be a sale of a considerable portion of their stock at the former establishment, by Messrs. Protheroe and Morris, from Tuesday to Thursday next, inclusive (May 17 to 19). Orchidists, knowing the valuable character of the plants at the Clapton Nurseries, are not likely to miss an opportunity like the present for securing some of the good things that will be offered.

ANSWERS TO CORRESPONDENTS

Editorial communications should be addressed to the Editor of the GARDENERS MAGAZINE, 148 and 149, Aldersgate Street, E.C.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, &c., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

Secretaries of horticultural societies are invited to send early notification of forth coming exhibitions and meetings, and are requested to advise us concerning change of dates

Vines.—J. H. Taunton: Do not give any more manures, or the vines will neither produce leaves or fruit; let feeding alone for a year and in the meantime grow the vines as hardily as possible, and endeavour by all the usual means to secure thoroughly ripened growths so that fruit may be secured next season. Write us again later as to the progress made.

Rusty Pear Foliage.—E. C. K., Ramsey: The foliage has evidently been touched by frost or keen wind while moist and tender, with the result that most of the life has been taken out of the leaves and they have turned brown. Should any leaves on other branches show rusty patches when they reach a more advanced stage send them along, if there is an appearance of attack, as this may prove another matter.

Saving Leaves in Autumn.—W. K., Warwick: If the leaves are intended for use with manure for heating and forcing they should be gathered when dry or moderately so. If gathered when very wet they pack closely together and soon rot; wet leaves also heat quickly, and that is exactly what is not wanted for hotbeds, but rather a steady heat prolonged as long as possible. Leaves gathered for hotbeds should be protected from heavy rains by being placed under an open-sided shed or by covering with a few sheets of galvanised iron.

Twin-spathed Richardia.—T. W., Milford Haven: Though not of frequent occurrence it is still not uncommon to find amid a very large batch of Richardias one or more inflorescences having two or more spathes. We have seen specimens with three highly developed spathes on one stem, but such freaks are anything but pretty. The example you sent has two large spathes, but it is scarcely so handsome as the single form. Such freaks as this usually occur where Richardias are well and strongly grown, and seem in some measure to be an outlet for superabundant energy.

Yellow Pear Leaves.—T. W. N., Chelmsford: The yellow blistering is no doubt due to a severe chill acting upon and disorganising the tissues of the leaf after a spell of mild moist weather, and probably acting in conjunction with a poorly-drained soil. Too heavy a mulching that would prevent the sun from warming the soil might have a good deal to do with the damage. See that the drainage is improved as far as possible at this date, and later on when the fruits are swelling give the tree an occasional supply of liquid manure if the weather is not continually wet.

Climbing Rose in Greenhouse.—A., Ashford: There is a local cause with which we are not conversant acting to prevent the rose from flowering. It may be excess of moisture due to poorly drained border, lack of air on favourable occasions, and absence of sufficient sunshine, owing to shading, to properly ripen growth. The shoots indicated by the red lines should have afforded abundance of blooms but it would not be good policy to cut them back now. Leave them until the autumn or winter and then cut them back two or three eyes. Allow the strong growths to do their best and if they ripen well they need only be shortened after the fall of the leaf; let them go up and do not stiffly train them horizontally. We shall be glad to assist you further if necessary.

Celery on Level Ground.—B. F., Horsham: Celery can be grown, and grown well, both on the level ground, and even on raised beds; but it is usual to cultivate it in trenches, because here the roots can be kept cool and moist better than under the other conditions. For level beds the soil should be of the best, thoroughly worked and mixed with crumbling decayed manure, and also a goodly quantity of the ashes resulting from burning or charring garden refuse. Though such beds should have been made up ere now, it is not too late if suitable materials are at hand. Blanching can easily be effected by the use of stout brown paper and by earthing, using boards to keep the soil in position. Much fine celery is grown thus, but trench culture is generally the safest and certainly the easiest, especially where large quantities of this and other vegetables have to be provided,

Mertensia siberica.—L. O. F., Andover: This handsome early-flowering herbaceous plant presents such a charming appearance when it is in good condition and crowned with drooping racemes of mauve-blue flowers, that it is very reasonable you should desire to know any of its peculiarities. Almost any soil will suit it, but it thrives as well in a light, but not dry soil, as anywhere, especially if a little mulch is given during winter. It needs to be planted where it is sheltered from the prevailing cold winds, otherwise its beauty will be spoiled. Then, also, to keep it in condition for as long as possible it should be protected from the early morning sun during the time it is flowering, otherwise it soon loses its charm if after a few degrees of frost the sun's rays act upon it directly; if a cupressus or other dense tree shades the plant until frost has disappeared, the mertensia lasts in flower a long time.

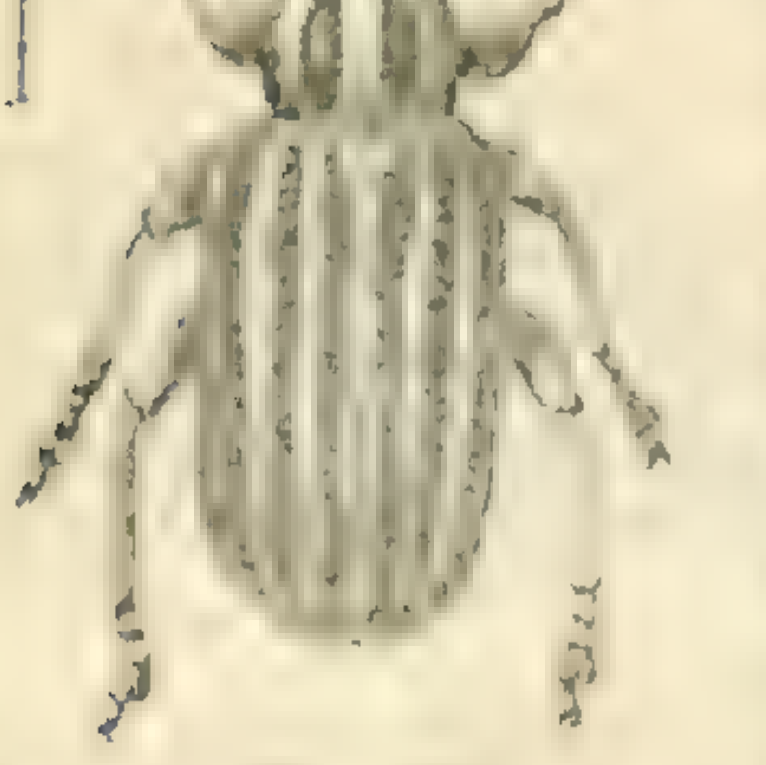
Tea and H.P. Roses.—Amateur, Ashford: Two dozen of the best H.P. roses for your purpose are Alfred Colomb, A. K. Williams, Beauty of Waltham, Captain Hayward, Ulrich Brunner, Abel Carriere, Charles Lefebvre, Horace Vernet, Prince Camille de Rohan, Francoise Michelon, Heinrich Schultheis, Victor Verdier, Her Majesty, Jeannie Dickson, Mrs. J. Laing, Suzanne, Marie Rodocanachi, Baroness Rothschild, Merveille de Lyon, Madame Hippolyte Jamain, Pride of Waltham, Margaret Dickson, Duke of Edinburgh, General Jacqueminot, and Boule de Neige. Two dozen good tea and noisette roses are

Anna Olivier, Catherine Mermet, Comtesse de Nadaillac, Hon. Edith Gifford, Ernest Metz, Francisca Kruger, Maman Cochet, Madame Cusin, Madame de Watteville, Souvenir d'Elise Vardon, Caroline Kuster, Madame Hoste, Maréchal Niel, Innocente Pirola, Niphetos, Souvenir de S. A. Prince, The Bride, Devoniensis, Rubens, Medea, Madame Lambard, Jean Ducher, Perle des Jardins, and Alba Rosea.

Erection of Fence.—W. S., New Malden: The question whether you or your neighbour should erect a fence can only be answered after a careful consideration of the conditions under which the land was purchased. Usually when land is sold in parcels, it is stipulated that the purchasers shall erect certain fences, and probably this was done in your case. If an examination of these conditions should show that your neighbour should provide the fence required for the separation of the two parcels, your proper course will be to call upon him to erect the fence, and intimate that you will hold him responsible for any damage that may be done by cattle in consequence of his failure to do so. Should there be no stipulation as to the erection of the fence, either in the conditions of sale or of the conveyance, you might consult a solicitor with reference to the matter, or proceed to protect your stock with a fence; and posssibly the latter course will be preferable.

Variation in Seedling Maidenhair Ferns.—C. A. N., Doncaster: All seedling plants when grown in quantities present to the experienced eye a large amount of variation, notwithstanding the general fact that many good species of ferns and flowering plants come very true from seed. Wherever several species and varieties of maidenhair ferns are grown together in the same house there is likely to be a considerable variation from the spore parent in the resulting seedlings, for the spores are so minute and easily carried from one plant to another by air, water, &c., that unless very great care is taken it is almost impossible not to sow other kinds than that you intend to propagate. This being so, it follows that several kinds of maidenhair ferns may be sown together, quite unintentionally, and then when the prothallus stage of germination has taken place, the sexual stage is reached, and so what to all intents and purposes is hybridisation or cross-fertilisation ensues. Very frequently it is possible in seedlings of maidenhair ferns to tell what the parents have been, so well are their characteristics combined in the progeny.

Forcing Seakale.—A. C., Rochester: There is no great art in the forcing of seakale, provided the plants have been well grown, the crowns properly ripened and kept, and that warmth and darkness can be provided. The question as to the soil in which seakale should be forced is a simple one, and easily answered; practically any material that will hold moisture, will not ferment, and can be presssed around the crowns, will do. You seem surprised to have seen seakale produced in boxes eight or ten inches deep; many folks would have very little seakale if they did not grow it in boxes. We grow first-rate seakale by putting the crowns about three to four inches apart each way in boxes sufficiently deep to hold the root-stock; the material we use is cocoa-nut fibre refuse, as it is easily carried about, and after use is available for other purposes. Over the box of crowns we invert another box of the same size, and stand the lot in a cupboard where the water-box for the supply of the kitchen boiler keeps the atmosphere somewhat moist. Waterings with warm water are occasionally given. Later batches are produced in the cellar without any artificial heat to assist them. The secret of the whole matter is to thoroughly cultivate the thongs, and so obtain stout stocks each with a single fat and well-ripened crown.



STRIPED PEA WEEVIL.

Pea Weevil.—R. S. M., Worcester: The pest from which your peas are suffering is the striped pea weevil (*Sitones lineatus*). It sometimes does enormous damage over large pea-growing districts, consequently every possible means should be taken to remove it. The weevils first appear during March, and later broods arrive during April and May to prey upon the new pea growth. The margins of the tender leaves are first attacked, and if not stopped the pest passes on to the succulent stems. The perfect insect does this much damage, while the grubs work under the soil and feed upon the more fleshy portions of the roots, so that between insect and grub the pea plants have a bad time of it. Soot and lime should be applied to the rows and between them, as it makes matters distasteful to the pest; in damp weather soot should be used frequently to render the plant obnoxious to the voracious beetles. Then also it is wise to promote rapid growth by occasional top-dressings of stimulating growth, and by applications of clear water in dry weather supplemented by liquid manure as the peas become strong and well rooted.

Successional Flowers.—C. H. B., Norwood: A careful perusal of the columns devoted to Work for the Week, would enable you to determine what to plant, sow, or propagate of the various plants that would serve to provide a succession of flowers the whole year round. Limits of space prevent us from giving such a detailed account as you desire in this column. If, however, you have a file of the GARDENERS' MAGAZINE for 1897, and those numbers of the present year up to date you should find no difficulty in the matter. You are, however, seriously handicapped by lack of a warm pit or intermediate house where a moderate amount of forcing could be conducted. In the winter you might have bulbous flowers of various kinds, provided they are potted early in autumn; there would also be cyclamen, and primulas, azaleas, bouvardias, and forced spiræas, arum lilies, winter-flowering begonias, &c., not forgetting Helleborus niger, for Christmas and the new year, out of doors. For spring, many of these subjects would still be available grown in frames or out of doors, with lily of the valley, zonal pelargoniums, eupatoriums, cinerarias, wallflowers, primroses, polyanthuses, violas, &c., and late flowering narcissi to keep up the supply until the early summer flowers commence. In the summer abundance of flowers can be obtained if a large garden is provided; roses would naturally be largely used, with liliums of sorts, sweet peas in plenty, irises of sorts, sweet sultan, cornflowers,, pyrethrums, double and single, candytuft, begonias, phloxes, carnations, &c., &c., with gladiolus, dahlias, michaelmas daisies, early flowering chrysanthemums, and helianthuses for autumn use. Following these are the great bulk of chrysanthemums to be housed in the greenhouse, and salvias, bouvardias, early cyclamen and primulas to help things along until the forced flowers and hellebores are in use. The latter might be made much of if grown liberally and covered with frames or handlights as soon as the buds are fully formed.

"CRITICISM WILL FOSTER TALENT," is an adage too well known to need dilating upon, especially as it is necessary to speak of something which for many years has defied adverse criticism. Holloway's Pills and Ointment, as sterling remedies for all complaints, are more familiar than "household words," being in constant daily use by thousands of people, who look upon their possession as a positive necessity. Leading medical authorities advise their use as reliable medicines in times of need. As a certain cure for all skin diseases they are unequalled, whilst for bile, sick headache, flatulency, indigestion, and all liver and stomach disorders, it has been truly said they are worth their weight in gold.—[ADVT.]

NEW INVENTION.

New Lawn Mower.—We recently had submitted to us one of [illegible] Follows and Bates' new "Chain Tennis" Lawn Mowers. A great [illegible] possessed by this is the use of an admirable, although simple, device for [illegible] the gear chain. Behind the drum, or cylinder, is placed a lever that [illegible] axle of the drum, upon which the driving wheel is fixed; thus, when the [illegible] hanging loose a slight movement of the lever draws the wheel to any [illegible] distance, and the chain is consequently tightened, and fixed in position for further service. The Gorton firm are introducing upon their invention a quality of chain equal to that used in the production of the best cycles. This machine also possesses an attachment for adjusting the cutting cylinder to any required height, so that any desired length of cut may be ensured, and the method is so easy that those who have had no great experience can readily make the necessary adjustment.

MARKETS.

Covent Garden.

THE moderate supply of fruit meets an eager demand, and prices are high. Oranges sell at high rates, but lemons are somewhat cheaper. Vegetables are abundant and sell at moderate rates, though for forced or early imported subjects the prices are high.

FRUIT.—Tasmanian apples, 10s. to 16s.; Californian, 8s. to 11s. per case; Nova Scotian, 15s. to 25s. per barrel: English grapes, 3s. to 4s. 6d.; Channel Islands, 3s. to 4s.; Dutch, 2s. 6d. to 3s. 6d. per lb.; pineapples, 2s. 6d. to 4s. 6d. each; bananas, 5s. to 9s. per bunch; Valencia oranges, 12s. to 25s. per case; Jaffa, 10s. to 12s. 6d. per box; lemons, 8s. to 15s. per case.

FLOWERS.—Arums, 2s. to 4s.; carnations, 1s. to 3s.; eucharis, 3s. to 4s.; gardenias, 1s. to 3s.; Lilium Harrisi, 2s. to 4s.; tea roses, 6d. to 1s.; pink roses, 3s. to 6s.; red roses, 2s. to 4s.; cattleyas, 6s. to 9s.; Odontoglossum crispum, 1s. 6d. to 4s.; and tuberoses, 1s. to 1s. 6d. per dozen blooms; Adiantum cuneatum, 4s. to 8s.; marguerites, 2s. to 4s.; narciss, various, 1s. to 3s.; daffodils, 1s. [illegible] to 4s; tulips, 3s. to 6s.; mignonette, 2s. to 4s.; pelargoniums (scarlet), 4s. to [illegible]; wallflowers, 2s. to 3s.; polyanthuses and cowslips, 1s. to 1s. 6d.; primroses, 9d. to 1s.; bluebells, 9d. to 1s.; and violets, 9d. to 3s. 6d. per dozen bunches; azaleas, 6d. to 9d.; stephanotis, 4s. to 6s.; lily of the valley, 6d. to 1s.; and pelargoniums, 4d. to 6d. per dozen sprays: bouvardias, 6d. to 8d.; white lilac, 2s. to 3s. per bunch.

VEGETABLES.—French asparagus, 2s. to 5s.; giant, 5s. to 7s. 6d.; Worcester, 1s. 9d. to 2s. 3d per bundle; mushrooms, 6s. to 9s.; eschallots, 2s. to 2s. 6d per 12 lb.; broccoli, 6d. to 1s per dozen, 3s. to 4s. 6d. per crate; new carrots, 6s. to 8s. per dozen bunches; spinach, 1s. 6d. per bushel; cabbages, 3s. 6d. to 4s. 6d. per tally; Egyptian onions, 6s. to 8s. per cwt.; English spring, 2s. to 3s. per dozen bunches; green peas, 4d. per pocket; French beans, 3s. to 3s. 6d, per basket; rhubarb, 2s. to 3s per dozen bundles; cucumbers, 2s. to 5s.; endive, 1s. to 1s. 6d.; lettuce, 6d. to 9d.; cos, 1s. 6d. per dozen; seakale, 6s. to 12s. per dozen punnets; Canary new potatos, 9s. to 12s.; Algiers, 10s. to 15s.; Malta, 8s. to 10s. per cwt.

Borough Potato Market.

In view of the increasing supplies of new potatos the demand for old tubers is slackening somewhat. Prices, however, remain firm owing to moderate supplies generally. Dunbars, 130s. to 140s.; Scotch Magnums and Hebrons, 110s. to 120s.; Bruce Maincrop, Sutton's Regents, Reading Giant, and Saxons, 100s. to 110s per ton; Belgians and Germans, 4s. 9d. to 5s. 3d per bag. New—Maltese rounds, 11s.; Teneriffe kidneys, 14s. to 15s. per cwt.; Lisbon rounds, 5s. to 5s. 6d. per box; Jersey hothouse, 3½d. per lb.

The mean reading of the Barometer during the week at Greenwich was 29·64 inches, and that of the Thermometer 51°·9, the latter being 1°·9 above the week's average in the 50 years 1841—90. The direction of the wind was variable, the horizontal movement of the air being 28 per cent. above the week's average in the 16 years 1860—75. The duration of registered bright sunshine in the week was 36·6 hours. The measured rainfall amounted to 0·58 of an inch.

ENGAGEMENTS FOR THE ENSUING WEEK.

MEETINGS.

WEDNESDAY, MAY 18.—Society of York Florists: Second exhibition.

FRIDAY, MAY 20.—Royal Botanic Society's Lecture.

SATURDAY, MAY 21.—General Meeting of the Royal Botanic Society. Tam[illegible] Viola Exhibition.

AUCTIONS.

MONDAY AND FRIDAY, MAY 17 and 20.—Japanese Lilies, Asters, Carnations, O[illegible] Seaforthias, Phloxes, Hollyhocks, &c., Protheroe and Morris's rooms.

TUESDAY AND WEDNESDAY, MAY 17 and 18.—Greenhouses, Hot-water [illegible] Garden Utensils, The Surbiton Nurseries, Ewell Road, Surbiton.

WEST'S
PATENT
IVORINE
PLANT LABELS
NAME TO BE WRITTEN ON WITH ORDINARY LEAD PENCIL OR PEN AND INK.

THE "IVORINE" WRITING DISC

Being made of a specially prepared substance, having the properties of real ivory, is imperishable, and does not corrode or eat away, like wood and metal labels; and being ivory-white, when written upon it shows to perfection. And also, as the writing is on the Ivorine itself it is permanent, though washable, and does not become unreadable, as is the case with all painted labels, as the paint gets old. It is for all purposes, and will last a century, either in a greenhouse or out in a garden, and not only is it always ready for use, and may be written on both sides, but the name when written in pencil may be easily rubbed off, and so used as many times as desired.

Samples and Lists of the West's Patent Specialities post free.
Price, **9d.** per dozen; **8s.** per gross, Carriage Paid.

BOROUGH OF WIDNES.

QUEEN'S DIAMOND JUBILEE COMMEMORATION.

The Commemoration Committee invite Competitive Designs for the laying out of a Park and Recreation Grounds at Appleton in the said Borough. The following premiums will be paid to the respective authors of the designs placed first, second, and third in order of merit:—1st, £36 15s.; 2nd, £10 10s.; 3rd, £5 5s. The conditions of the competition, with a plan of the site, may be obtained on applying to Mr. John S. Sinclair, A.M.I.C.E., Town Hall, Widnes, on payment of £1, which will be returned on receipt of Competitive Drawings, or on receipt of the conditions and plan, in case the applicant does not compete. Plans, &c., to be sent in addressed under motto to the undersigned by July 1, 1898.

H. S. OPPENHEIM,
Town Clerk,
Hon. Secretary.

NOTES OF THE WEEK.

THE TEMPLE SHOW.

SO popular have the exhibitions annually held by the Royal Horticultural Society in the gardens of the Inner Temple become amongst all classes of horticulturists, and an important section of the general public, that it is highly gratifying to learn that the show for the current year, which opens on Wednesday next, has the promise of proving one of the best of the series. It will not surpass in extent the largest of the Society's gatherings in these gardens, for that is an impossibility, in consequence of the restrictions imposed upon the Council by the Temple authorities in generously granting the use of the gardens. It is felt by the governing body, and properly so, that as much space as can be well spared is given up to the tents, and that it is therefore not desirable there should be an increase in either their number or dimension. Had it been possible to increase the accommodation under canvas to that extent there would have been no difficulty in increasing the display to at least double the size of last year, for fully three times the available space has been applied for. Therefore, whatever superiority the exhibition may possess over the best of those previously held, will be in interest and attractiveness. Judging from our correspondence of the past few weeks we have reason to believe that there will be a considerable accession of new exhibitors, and we shall be pleased if our anticipations upon this point are justified by the results, not because we do not appreciate to the fullest possible extent the efforts that have been made by those who have contributed so materially to the splendid success that has been achieved in past years, but new exhibitors are likely to considerably enhance the interest of the exhibition by presenting new objects and by staging their products on lines differing from those followed by the regular exhibitors. Freshness in public exhibitions we regard as of primary importance, and any departure that may be made from the stereotyped arrangements will be as welcome in the Temple Gardens as elsewhere. We cannot hope for such a richly diversified exhibition as that which produced so profound an impression upon visitors to Hamburgh twelve months since, or so brilliant and tasteful a display that filled with admiration the minds of those who had the satisfaction of assisting at the Ghent Quinquennial a month ago; but it is not unreasonable to suggest that the Temple Show might be rendered more attractive than is usually the case. It is impossible, in the space at the disposal of the Council, to produce the picturesque effects for which the exhibitions at Hamburgh and Ghent were remarkable, but exhibitors should have no difficulty in arranging their products with some degree of taste. Unfortunately, a considerable proportion of those who contribute to these exhibitions regard mere quantity as of primary importance, and in carrying out their views so crowd the space allotted them as to suggest a series of stalls in Covent Garden Market rather than an exhibition of the Royal Horticultural Society. If the general body of exhibitors would stage about two-thirds the quantity of plants and flowers that they now consider desirable, and be careful to select the very best, their exhibits would be immensely improved and the general effect in each of the tents be materially enhanced. Nowhere on the Continent is it possible to see such large displays of orchids, of hardy plants, or of cut flowers, and, knowing the superiority of the Temple gatherings in these respects, we are anxious that they should evince taste of a high order, and afford object lessons of special value to those who are responsible for provincial exhibitions.

ROSE EXHIBITING.

WE have so strongly advocated the desirability of presenting roses, and indeed other classes of flowers, to public notice in their most attractive guise, that we are pleased to observe in glancing through the schedule of prizes offered for competition at the exhibitions of the National Rose Society that the decorative aspects of roses is being more fully appreciated by the leading rosarians. The Society has not, perhaps, gone so far in this direction as we could have wished; but in view of the objection which so many have to a material divergence from well beaten tracks, it is no doubt wise, on the part of the executive, to proceed slowly in effecting reforms in methods of staging. We have considerable sympathy with our distinguished coadjutor, the Rev. J. H. Pemberton, in his desire to increase the interest and relieve the flatness of the seventy-two's by the introduction of sprays of the beautiful garden roses, but we are more strongly impressed with the importance of abolishing the use of boxes of the orthodox pattern in the classes for small numbers of blooms. For example, it would be an exceedingly pleasing change to have the contributions to the open classes for twelve blooms of the same variety staged in plain substantial vases or other receptacles, with stems of moderate length, and carrying rich green foliage. Equally pleasant would it be to see the sixes and fours in the amateurs' classes staged in a similar manner. The rosarian, when he cuts his roses for the enjoyment of his friends and himself does not remove them from the plants with a few inches of stem and thrust them into holes cut into a flat board. He cuts them with a sufficient length of stem for the blooms to have several leaves as a contrast to their varied hues, and inserts them singly or several together, in neat but elegant vases. In taking this course the rosarian acts wisely, inasmuch as he presents the products of his skill in a manner likely to give the greatest pleasure, and this is exactly what should be done at the public exhibitions. It is sometimes contended that it would be impossible to determine with the proper degree of exactitude, the relative merits of roses so staged, but we attach no importance to these contentions as we are fully persuaded that those qualified to judge roses, would just as readily pronounce an opinion upon six or twelve blooms arranged in a vase, as they would upon the same number placed on the orthodox box. We are pleased to observe that garden roses receive largely increased encouragement at each of the exhibitions of the National Rose Society, more especially as we know that the classes would have been still further increased, and the value of the prizes augmented, had the funds of the society permitted. In future years we hope to see a further development in this direction, and trust that increased support will be forthcoming to permit of this being done, for, arranged in light bouquets, the garden roses add immensely to the interest of the shows, and greatly enhance the artistic effect, which is so desirable at rose and other exhibitions of cut flowers.

ARTIFICIAL ROOT PRESSURE.

ONE of the most interesting facts relating to vegetable physiology is unquestionably the remarkable absorptive action of roots, and the power they possess of forcing up the moisture they have taken from the soil throughout the system of the plant. This power, commonly known as root pressure, which has so important a bearing upon the life of the plant, has long been recognised, and so far back as 1737, Hales published the results of some ingenious experiments he had conducted for the purpose of measuring the force of the pressure. In the case of the grape vine Hales found the pressure sufficient to force a column of mercury to a height of thirty-nine inches; but according to the investigations of Clark, who published the results rather more than a quarter of a century ago, the root pressure of the black birch is nearly double that of the grape vine. Many other investigations have been made, both in this country and on the continent of Europe and America, but until the experiments initiated by Professor Goff, it does not appear that any endeavour was made to turn the knowledge to practical account. It is generally known that if the fibrous roots furnished with root hairs have been destroyed in the process of transplanting, the leaf buds expand much more slowly than do those of trees that have not had their roots disturbed, and this retardation of development is undoubtedly due to the reduction in the root pressure, or in the force with which the moisture absorbed from the soil is distributed over the system. The cells of the buds can readily absorb water and the roots can take up the water without root hairs, but they cannot do this with sufficient rapidity to ensure the buds obtaining the supplies necessary for the development of growth at the usual rate. Recognising these facts, Professor Goff was induced to make some experiments with a view to determine whether artificial root pressure might not be applied to newly-transplanted trees with advantage, and, according to the annual report of the Wisconsin Experiment Station, successful results were obtained. In conducting the experiments a quantity of distilled water was supported at a height equal to or slightly exceeding that of the tree, and connected by means of a tube with the cut end of one of the principal roots. The water used was contained in a round glass flask, holding about two quarts, and fitted with a rubber cork having two vertical holes through it. In one of these holes a short glass tube was inserted, and to this a rubber tube was attached, and in the other hole a glass tube, reaching nearly to the bottom of the flask was inserted for the purpose of supplying the air required for ensuring the necessary pressure. The flask was inverted on a small platform fixed to a stout post, and the tube connected to the root by being slipped over the cut end and tied on tightly. The trees, it may be added, had their roots pruned rather severely, and when the tube had been attached to one of the roots of each tree the soil was placed about them in the usual way. Professor Goff states that the effect of this root pressure was very quickly shown—in some cases within a few hours. The development of new growth was so greatly accelerated that some of the trees artificially treated commenced to make new growth eighteen days in advance of those to which no artificial pressure was applied. The water flasks remained attached to the trees until the middle of August, but no advantage was gained therefrom, and Professor Goff is of the opinion that the benefit derived from artificial root pressure is limited to aiding the tree in the production of new roots. After new leaves have been developed roots furnished with hairs are produced in abundance, and normal root pressure commences, and this, combined with the suction from above due to the transpiration of the leaves, is sufficient for the distribution of moisture through the system. Although the application of artificial root pressure is out of the question when large numbers of trees are planted, there may be single specimens to which it may be applied with advantage, and the experiments raise a question of much interest to horticulturists.

The Temple Show.—We shall give in our next issue a special and fully-illustrated report of the Royal Horticultural Society's exhibition to be held in the gardens of the Inner Temple on Wednesday and the two following days.

The Bluebell (*Hyacinthus nutans*) is one of the most beautiful of our plants that bloom during the spring season; and as it readily lends itself to artistic treatment, it is gratifying to observe that it is being freely used in the embellishment of the garden. Naturally, the "Blew Harebel, or English Jacint," as Gerard loved to call the plant, is to be found "In the lonely copse and shadowy dell," and this fact has suggested its suitability for the carpeting of shrubbery borders and for clothing bare spaces under trees. At Kew it has been employed largely and with singularly good effect for both purposes, more particularly in the azalea garden, which forms a very attractive feature of the arboretum. The bluebell is also used in planting on the araucaria mound in the botanic garden, and this, now "deck'd with a thousand flowers of grace divine," presents an exceedingly beautiful effect. "Fresh Hyacinthus," as Spenser designates the bluebell, will also the "turf bestrow," and this fact has been taken advantage of by the Kew authorities, and many thousands of bulbs have been planted in the grass in the arboretum and other parts of the gardens; and, beautiful as are the effects produced in the shrubbery borders and under the wide-spreading branches of trees, they are surpassed by the great sheets of azure flowers in the grass. At Syon also the bluebell is planted extensively in the grass, and presents, as at Kew, a charming appearance.

The French Vineyards have suffered severely of late years from insect depredations in consequence of the insane practice of killing the birds whose chief food consists of insects or their larvæ. This matter is prominently referred to by Mr. Consul Hearn, in his latest report on the trade of Bordeaux to the Foreign Office. In his observations on the folly of destroying useful birds, he points out that the appearance of the cochylis, a most destructive insect, is contemporary with the destruction of small birds in the vineyards. No sooner does the "chasse" open than every man and boy is seen with a gun stalking and "potting" every small bird he can get near enough to. The consequence is that there is literally no bird life among the vines, and consequently insect life now reigns supreme. On one property alone from July 20 to September 10, 1897, 5,000 days' labour of women and children was alone employed in looking for and destroying the eggs and larvæ of this insect. "But only birds were allowed free action they would," the Consul says, "assuredly, gladly accomplished this work, and the women and children might be employed in remunerative labour. In the streets of Bordeaux during the autumn and winter thrushes and starlings are offered for sale by thousands, and yet these birds live exclusively on insects." We are glad to learn that a Bill is to be shortly introduced into the Chamber for the protection of birds "useful to agriculture."

Castle Ashby and its Gardens.—With the GARDENERS' MAGAZINE of June 4 we shall present a special supplement, in which Castle Ashby, the seat of the Marquis of Northampton, and its great gardens will be fully described and illustrated. The illustrations of the gardens will include the rose garden, lake and water lilies, Italian garden and conservatory, interior of the great conservatory, Prior's Walk and hardy flowers, Italian archway, view on upper terrace, lower terrace garden, and picturesque trees In addition to the foregoing a double-page plate of the mansion will be given. There will be no extra charge for this issue, and, as a large demand is anticipated we would strongly advise those of our readers who require additional copies to give their orders at once, and thus avoid the disappointment which has been experienced by readers in failing to obtain copies of some previous issues with which supplements of great gardens were given.

A Double Form of Berberis Stenophylla has originated with Messrs. Fisher, Son, and Sibray, of the Handsworth Nurseries, Sheffield. It is like the type in colour and habit save that the golden flowers are very double and unusually persistent; as an early flowering shrub the new form will be welcome as adding variety to the already large number of elegant free flowering shrubs available for garden decoration early in the season. Berberis stenophylla is itself a hybrid between B. Darwini and B. empetrifolia, and now one of the best known of the Barberries. It is elegant and handsome, free and bright, and it seems only in accordance with the general fitness of things that the new double variety should have originated with the Sheffield firm, by whom the parent was raised and distributed. It should be remembered that B. stenophylla is uninjured by our severest winters, and that the flowers are followed by dark and rich purple berries of a most attractive appearance.

The Duke of Portland, in writing from Welbeck Abbey under date o May 11, with reference to his engagement as chairman at the forthcoming festival of the Gardeners' Royal Benevolent Institution, says: "I have promised to preside at the fifty-ninth anniversary festival dinner in aid of the funds of the Gardeners' Royal Benevolent Institution, on June 8 next, at the Hôtel Métropole, and I venture to ask for the kind assistance and support of all lovers of flowers and gardening. The charity—the only one of its kind in the United Kingdom—whose cause I have undertaken to plead, is now in its sixtieth year, and during its existence has distributed £74,000 to worn-out gardeners, market gardeners, horticulturists, and their widows, in distressed circumstances, and has now upon its funds 168 persons—93 men and 75 widows—who are receiving permanent relief at an annual cost of £3,060. To meet this expenditure the only assured income is £900, leaving the remainder to be made up by subscriptions and donations. Towards this object I earnestly solicit your generous help. I may mention that her Majesty the Queen has been the patroness of the charity for forty-six years, and has always evinced a warm interest in its welfare, and I can therefore confidently appeal on its behalf.

The Royal Society's Selected Candidates.—Fifteen candidates have been selected by the council of the Royal Society to be recommended for election into that body during the present year. Of these fifteen four have special interest for our readers by reason of their successful studies in botany, geology, and meteorology. Mr. Arthur Lister, F.L.S., has become well known by reason of his researches in connection with Plasmodium, and still more so for his papers relating to the Mycetozoa. Mr. Albert Charles Seward, M.A., F.G.S., University Lecturer in Botany at Cambridge, has extensively investigated fossil plants, especially those of the Weald period, as shown by the two parts of "The Wealden Flora" from his pen, and already published. Mr. Alexander Buchan, M.A., LL.D., F.R.S.E., is the author of many important papers on meteorology, including the Challenger reports upon Atmospheric Circulation in 1889, and Oceanic Circulation in 1895; he is also author of "Meteorology" in the Encyclopædia Britannica. The gentleman whose geological investigations have led to his being a selected candidate for admission to the Royal Society is Lieut.-General Charles Alexander McMahon, vice-president of the Geological Society of London. He was the first to discover the granitic origin of the North Himalayan "Granatoid Gneiss," and has contributed valuable papers relating to the geological survey of India, the Lizard Rocks, and Dartmouth Granite.

Strawberries.—Few plants are being better helped by rains that fall so freely as are strawberries. Generally they are looking wonderfully well. There is ample relative foliage, and the promise of bloom is great. It only needs open, mild weather with abundant sunshine to ensure its setting, and another grand fruit crop will be assured. We are now at a critical period of the month, for the twentieth, or thereabouts, often times brings one or two sharp frosts. We may well hope that no more such visitations will trouble us this spring. The value of mulching is much enhanced when the weather is dry, but with frequent rains and moderate sunshine, the longer the work of mulching can safely be deferred [illegible] better. Not only will it be less saturated for the fruits to be upon, but the [illegible] be less cold, a matter of great importance, for soil warmth is essential to the [illegible]ing, colouring, and flavouring of the fruits. Dressings of artificial manures should be given only where the soil is poor, and growth moderate. Such dressings, where the soil is in good condition, would, with such frequent showers, rather tend to excess of foliage production than the development of solid, high-flavoured fruits. It is very interesting to learn from Mr. Norman, of Hatfield House Gardens, that in producing such really grand fruits as he exhibited of Royal Sovereign at the recent Drill Hall meeting he gives but little artificial food. Early rooted runners are potted in due course into six-inch pots in which is one-third drainage, [illegible] compost consists almost entirely of rather fresh turfy loam of the best quality and a little soot added. The potting is very firm. The plants are during the winter plunged in ashes out of doors, and are put into frames only just before needed for forcing. Each plant carries about ten fruits that are very solid, and of the best possible flavour.

Hybrid Cinerarias.—At the recent meeting of the Scientific C[illegible] the Royal Horticultural Society a collection of hybrid cinerarias from Mr. J[illegible] Woodside, Farnham Royal, Slough, created considerable interest. They [illegible] small selection of a numerous progeny, from a cross effected between C. [illegible] lanata and the cinerarias of gardens, the greater number of which were [illegible] semble the garden form; but the present ones had a tomentose stem and branches, as well as the under surface of the leaves, which also in form resembled C. lanata. The blossoms were rather small, some being a pure white, others [illegible] markable for their quantity. Unfortunately the best plant with white flowers refuses to set much, if any, seed; but it was hoped that Mr. James would persevere and try to establish a new race, which would certainly be attractive from the silvery appearance of the leaves.

The Northernhay Pleasure Grounds, Exeter, have been remodelled by Messrs. R. Veitch and Son, Exeter, under the superintendence of Mr. F. W. Meyer. The work has just been completed, and visitors are now able to judge, in a large measure, the very many and desirable improvements made, both in the beautification of grounds and for the accommodation of visitors. One of the most effective alterations has been carried out near the Bucknill Memorial, where, in place of ugly and unattractive slopes, a most picturesque rock-garden has been formed with boulders of real Dartmoor granite protruding from the ground as if they had been forced up by natural upheavals. A cavern is formed, over which small waterfalls emerge There is a miniature pond among the rocks, and it is studded with water-lilies and other suitable flowers, including the most beautiful of Marliac's nymphæas. The overflow water is made to do duty in supplying the necessary nourishment to a fairly large collection of bog plants, which naturally require a good deal of moisture. The plants include blue and yellow gentians, iris, arums, day lilies, and double marsh marigolds, with several ornamental grasses. Scattered among the rocks are edelweiss, mountain cress, harebells, alpine wallflowers, candytuft, phloxes, and other choice mountain plants. The east side of the Bucknill Memorial is very differently treated, though arranged so as to form a harmonius whole. It is designed in the shape of a mountain streamlet, with two small waterfalls supplied by a purling brook, which apparently emerges from the recesses of a little fern-lined rock cave. The overflow here also goes to supply different plants requiring plenty of moisture, and none of the water is wasted. The natural effect is further enhanced by a good collection of choice and native hardy ferns embedded among the rocks, and by the judicious intermixture of rock shrubs, such as the alpine rhododendrons, various species of gorse, rock cistus, and cytisus.

The Postmen's Park.—We are informed that the vicar and churchwardens of St. Botolph, Aldersgate Street, have purchased from the City Parochial Trustees the desirable piece of land in Little Britain that has been so much talked about of late. The terms are that the western portion will be handed over on June 24 next, on the payment of £6,000, and the eastern portion will be conveyed on the payment of a further sum of £6,000, if made within two years from that date. Mr. Norman, the senior churchwarden, has sufficient money subscribed to meet the payment of June 24 next, but needs £3,000 for the second payment,

Horticultural School.—The county School of Horticulture at Chelmsford continues to do excellent work in the teaching of both science and practice to youths engaged in gardening, and during the last season special attention was devoted to the propagation of plants and fruit culture. The school is held in the newly-erected biological laboratory, which is found to be admirably suited for the particular kind of work carried on in the horticultural courses. Referring to the work of the school, the Board of Agriculture's inspector observes in his report: "The most important part of the horticultural work of the Essex Technical Instruction Committee has been the various courses of horticulture at the laboratories at Chelmsford, in continuation of those initiated during the preceding year. No less than five of these, each lasting for three weeks, were held, and the total number of pupils was seventy. The work carried on is scientific and practical, and whenever inspected has appeared of a high order. The class, too, who attended are of the right sort, as they all come straight from gardens to attend the courses." It is satisfactory to know that the training received at the school is not intended by the authorities to be the end, but rather the beginning, of the young gardener's technical education. The aim of the combined laboratory and garden work is to teach right methods, to stimulate original thought, and to arouse in the mind of the pupil a desire to investigate things for himself. It is, in fact, part of the scheme of horticultural education inaugurated by the committee that students, after leaving the school, take up some special line of study for themselves, and so carry on the work already begun in the class-rooms. It is only by such methods diligently and systematically pursued that anything but the very dimmest insight can be obtained of the intricate processes of plant life.

Decayed Peas.—Mr. Cooke, The Croft, Detling, Maidstone, forwarded to the R.H.S. Scientific Committee some young plants of the American Wonder pea, which had failed to grow. They were sown last November, and while many are doing well, others close by turned a sickly yellow. Mr. Sutton observed that his experience was that no wrinkled peas, as the above, were suitable for autumn sowing; the skins, being more delicate than those of round peas, will not stand the winter so well. This was, therefore, the probable cause of failure.

Fertilizers for Lawns and Pastures.—Lawns and pastures evincing a high state of fertility contribute so materially to the charms of the country house, that any information relating to their maintenance in a condition ensuring a vigorous growth of the grass should be taken full advantage of. For some time past the staff of the University Extension College, Reading, has, under the direction of Professor Gilchrist, been engaged in carrying out a series of experiments on the manuring of grass lands. These experiments were made at fourteen centres, and the results show conclusively that phosphatic manures are most useful for improving pasture, both in bulk and (especially) in quality. On the whole, basic slag has been the most economical and effective phosphatic manure for this purpose; at Marlston and at Shinfield it has given excellent results four years after its application. As a rule a potash manure (as kainit or sulphate of potash) has been useful on the lighter soils, especially in improving the quality of the herbage and developing leguminous plants; on the heavier soils potash manures have, as a rule, not been effective. Nitrate of soda has generally increased the bulk considerably in the first year, but has made the pasture coarser; after the first year the pasture has almost invariably been coarser where this was applied, whether the plot has been grazed or mown, and the conclusion must be arrived at that even one dressing of nitrate of soda applied to a pasture will, in after years, do considerable damage; this has been the case whether the nitrate of soda was applied by itself or in combination with other manures. Common salt has not been effective in improving pasture, and in no case has lime given anything like a profitable return. In most cases basic slag has given the results generally attributed to lime at a much less cost. The results at Herriard show that where pasture is rough and benty, a good harrowing in the spring will do much to improve such land, and that manures applied after such a harrowing are more quickly effective. Basic slag, applied early in April, at Herriard, after a good harrowing, gave an excellent result on the grass crop of the same year.

Orchid Sale at Walton Grange.—The sale of surplus and duplicate orchids at Walton Grange, Stone, Staffordshire, the residence of William Thompson, Esq., a few days since, created an immense amount of interest, and there was a large muster of orchidists from various parts of the country. The collection is equally well known for the rarity of many of the forms and the splendid condition of the plants; and in addition to the attractions of the sale, there was an imposing display of flowers, which was considered by those present well worth a long jouney. The odontoglossums, lælias, and cattleyas were simply magnificent, and, being tastefully arranged, produced a beautiful effect. The sale was conducted by Mr. Protheroe, of the firm of Messrs. Protheroe and Morris, and among those present were Mr. Low, of Enfield; Mr. Godseff, of St. Albans; Mr. A. Outram, of Fulham; and Mr. Mason. There were many orchidists from Manchester, Bradford, Liverpool, Birmingham, and other provincial centres. There was a brisk competition for the plants offered, and good prices were obtained, the principal lots being: Odontoglossum excellens Thompsoni, two bulbs and one lead, £147; O. sceptrum aureum, four bulbs with spike, £147; O. Ruckerianum ocellatum, £52 10s; O. Stevensi, six bulbs and two leads, £115 10s.; O. meleagris, one bulb, £36 15s.; O. crispum Alfred, three bulbs, two leads, £26 5s.; O. sceptrum Argus, seven bulbs, two leads, £15 15s.; O. Wilckeanum concinnum, one bulb, one lead, £15 15s; O. crispum aureum, one bulb, one growth, £27 6s.; O. Crispum Katæ, £21 6s.; O. excellens, three bulbs, one lead, £21; Cattleya labiata Peteersi superba, three bulbs, one lead, £78 15s.; C. Victoria Regina, four bulbs; £46 4s.; Cattleya labiata cærulescens, two bulbs, one lead, £31 10s.; Lælio-cattleya pallans, £12 12s.; Cypripedium insigne Dorothy, one old and two new growths, £22; C. Leeanum superbum, one old and two new growths, £31 10s.; C. Rothschildeanum, £22. The sale was well arranged, and the plants in such excellent condition as to bring much praise to Mr. Stevens, the enthusiastic grower, who for so many years has filled this important post with the greatest satisfaction to his liberal employer.

Mr. W. H. Lees has been advising the members of the Wood Green Horticultural Club on the cultivation of crysanthemums, and had the advantage of addressing a large audience. In the course of his lecture Mr. Lees dealt in detail with the cultivation of crysanthemums generally and with the peculiarities and requirements of the leading varieties, and received a hearty vote of thanks at the close.

Freesia Bulbs—Mr. F. Egbert Hollond, Satis House, Yoxford, submitted to the R.H.S. Scientific Committee some bulbs which had been planted last July, had never thrown up any leaves, but had formed fresh bulbs upon the old ones, which had withered. It appeared to be a case common in potatos, when it is called super-tuberation; fresh tubers being formed at the expense of the old one. It was possibly due to the freesia bulbs having been planted at the wrong time of the year, energy being expended in a wrong direction.

Prize Essays.—The French Society for the Encouragement of National Industry offers for open competition a prize of £80 for each of the following: (1) The best report on the agricultural and rural economy of any one province or department; (2) the best report on the physical constitution and chemical composition of the soils of any district of France; (3) the best report on vine culture and on the influence of manures and of vinification upon the quality of wines; (4) the best report on the maladies of cider and on means for checking or preventing them. A prize of £120 is offered for the best report on the alcoholic ferments which are active in the manufacture of beverages, and a prize of £40 for a practical method of getting rid of certain pests of the grape vine. Competitions close on December 31, and papers have to be addressed to the Secretary, at 44, Rue de Rennes, Paris. The society awards each year a large gold medal to the writer who has exercised the greatest influence upon the progress of French industry during the previous six years; in 1899 this medal is to be assigned to agriculture.

The Structure of Dendroceros.—In a highly scientific paper by Professor Douglas Campbell read before a recent meeting of the Linnean Society, and dealing with the structure of Dendroceros, the author concluded that in its apical growth and the form of the thallus, Dendroceros differs decidedly from other genera of the order Hepaticæ. The archegonium corresponds in its structure to that of the other Anthocerotaceæ, and is intermediate in character between Notothylus and Anthoceros. The antheridium is solitary, and arises, as in the others of the order, endogenously. The first wall in the embryo is longitudinal, as in Anthoceros, but the first transverse wall determines the limits of the foot, as in Notothylas. The origin of the archesporium is from the amphithecium, as in the other genera, but it is less massive than in either of these. The division of the archesporial cells into sporogenous and sterile ones is less regular than in either of the other genera, and the primary archesporial cells may be transformed directly into sporogenous ones without any further divisions. In D. Breuteli the spores remain undivided, but in D. crispus they germinate within the capsule, and are discharged as multi-cellular bodies. The absence of stomata from the capsule, as stated formerly by Leitgeb, was confirmed.

SOME FORTHCOMING ROSES.

HAVING considered in the earlier numbers of the GARDENERS' MAGAZINE of this year, some of the new roses of 1894, 1895, 1896, and 1897, let us complete the series by glancing briefly at some of the roses promised to the rose world this spring and, at others which are still, and perhaps will remain for a year or two longer in the possession of the raisers. The southern exhibition of the National Rose Society held last year at Portsmouth will long be remembered for its grand display of decorative roses. Amongst the number of varieties staged at this show were two most promising seedlings, viz. Purity and Royal Scarlet.

PURITY, Hybrid Bourbon (George Cooling and Sons).—For the N.R.S. to award a "card of commendation" to Purity, a decorative rose, is both a sign of progress and also an indication of the excellence of this variety. Hitherto only so-called "exhibition roses" have stood any chance in this class, but a bunch of Purity in the "garden rose" division looked so very charming with its masses of flowers in all stages of its beauty, that the judges awarded it this commendation. The schedule requires three blooms only in the seedling or new rose class, which may be all very well for "exhibition roses," but does not meet the case of "garden roses." For these latter require to be shown in bunches, several stalks cut, each bearing clusters of flowers in all stages of development. Three flowers of Purity were staged in the stereotyped manner in the seedling class, but I do not think this rose would have won a card of commendation had it not been that the attention of the judges was called to the delightful bouquet of Purity staged in the decorative section. The flowers are small, but of good form, buds well pointed, colour white, something after the style of Madame Bravy, but more of the bourbon than tea. The growth was strong and bore masses of flowers on every shoot. It will probably become a most popular rose. We shall doubtless see more of it this season. Messrs. Cooling are sending it out in May this year, and give the following description: "In offering this new rose, we are sure we are introducing a distinct and desirable new variety. As a garden rose, or as a rose to grow for market for cutting, it will be equally welcomed. The colour is pure white, with a faintly flushed centre, the petals are stiff and of great substance, it is of medium size and perfect in shape. It was in flower last year in the open before any other double rose in the nursery, a row of it in June being simply one mass of blossom. It is of semi-climbing habit and appears to require only slight pruning. Owing to the earliness of its flowering we were able only to show it at one or two of the early exhibitions, where it was greatly admired by all rose growers who saw it."

ROYAL SCARLET, H.P. (Paul and Son).—This, probably one of the brightest of red roses, will be sent out in the early summer of this year. A lovely bouquet of it was exhibited last year at Portsmouth, its vivid colour attracting general attention. It is quite single, very free flowering, and should prove most serviceable for massing and ordinary decoration. Messrs. Paul, at Portsmouth, had staged it for setting up in their stand of "garden roses," but since, by the N.R.S. regulations, all hybrid perpetuals were excluded from this class, Royal Scarlet had to be left out in the cold. It was, however, staged separately, and very beautiful it looked, notwithstanding its isolation. It is a satisfaction to learn that the N.R.S. have at last partially relaxed this strict regulation, and from henceforth single hybrid perpetuals will be admitted into the "garden rose" section at the exhibitions. Royal Scarlet is the result of hybridising the semi-double hybrid perpetual Cheshunt Scarlet with either Alfred K. Williams or Marie Rady. Its dwarf habit will make it useful for bedding purposes, and it will doubtless soon find its way at exhibitions into the decorative rose classes where bright reds are much needed. It was awarded a "card of commendation" by the N.R.S., which is as much as could be expected for a single, or indeed any purely decorative rose under present conditions where three specimen blooms are required. When the time arrives that new seedling decorative roses competing for a gold medal may be staged in bunches or sprays instead of in the prevailing way of three stiff wired up flowers only, decorative roses may have a chance of winning a gold medal, but not till then. Messrs. Paul's description of Royal Scarlet is as follows: "A single-flowered H.P. of vigorous bushy habit, with reddish-brown foliage, and bunches of vivid scarlet flowers. This is, we think, the purest scarlet yet produced in roses; it is admirably suited for bedding."

Among the many seedlings exhibited at last season's rose shows by Messrs. Alexander Dickson and Sons, six are here singled out for special notice. With some of these we are already more or less familiar, having seen them in stands of new roses during the last two or three years, but they still remain in the hands of the raisers, and we must await their spring catalogue of new roses to see if any of them are to be offered to the public this year.

ULSTER, H.P. (A. Dickson and Sons).—A seedling of great promise, and which won a gold medal at the Metropolitan show of the N.R.S. at the Crystal Palace last year. The judges had little, if any, hesitation about this award, for there is a certain style or character about Ulster which stamps it as a good rose. In colour it is bright salmon rose, of good form and large size, with petals of considerable substance. Judging from the specimen ground plant shown at the Crystal Palace, it is very vigorous in growth. The raisers exhibited twelve fine blooms at Hereford rose show last year.

LADY MYRA BEAUCLERK, T. (A Dickson and Sons).—This rose is becoming quite a familiar feature among the roses staged by this firm. I think it was staged and named at Ulverston rose show as far back as 1895, and yet it is still a seedling! We watch year by year for its *début*, and when we see it figuring so frequently in the chief classes at the leading rose shows, it is surely reasonable to ask when My Lady is coming out? Some excellent trebles of it were set up at the Crystal Palace last year, and it was also seen in good condition at several other places during the season. I have taken quite a fancy to the rose, and wonder why she is kept in the nursery so long. The colour is hard to describe. It reminds one of Grace Darling, and yet it is not quite like it, with streaks of darker shade and of silvery reflex. But whatever the exact colour may be, it is quite distinct from anything else. It is of good form, with long pointed blooms.

DAWN (A. Dickson and Sons).—Another seedling of good character, a well-built flesh-coloured flower, the result of a cross between Caroline Testout and Mrs. Paul.

LADY CLANMORRIS, T. (A. Dickson and Sons).—A new seedling tea of apparently robust growth; flowers large, with much depth of petal. Colour, white, shaded saffron-yellow. The raiser had a fine bloom of this variety at the Crystal Palace last year.

BESSIE BROWN (A. Dickson and Sons).—A seedling exhibited for the past two years, but not yet sent out. This variety stands so near that indefinite line that divides teas from hybrid teas, that I fancy the raisers are at present somewhat undecided as to its classification. It was staged in good form at the Manchester Rose Show in 1896, and was then described as an hybrid tea. In 1897 it was exhibited as a tea. Messrs. Dickson state that it is robust in growth. Flowers, very large, beautifully formed. Colour, white, with pink centre.

MRS. CHARLES J. GRAHAME, T. (A. Dickson and Sons).—This was exhibited last year under the above name, but I believe when sent out will be called Alice Grahame. An attractive flower of it was staged at the Crystal Palace last season. The raisers state that this is a grand tea, very robust in growth, and flowering most continuously. The flowers are very large and milk white.

JOSEPH H. PEMBERTON.

BRITISH FERNS FOR INDOOR CULTURE.

WITH regard to the varieties of British ferns best worth growing indoors, the space, of course, which is at command comes largely into question, but in most window recesses small-growing species and varieties are to be recommended. As the catalogues issued by those in the trade who make a specialty of British ferns usually indicate the size, we cannot do better than refer to these, merely adding that the cost of many of the very best tasselled, curled, plumose, and curious forms is very small indeed, so that the actual expense need not be great. What I should recommend to those who may be unacquainted with this special culture, is to obtain one or two varieties, say, a frilled Hartstongue, a crested Lady Fern or so, and a crested male fern, and follow the rules cited in a previous issue for a season, until they see how beautiful the developments become. They will then be encouraged to try a few more, and so on; whereas for a novice to start with a number is more than likely to end in disappointment.

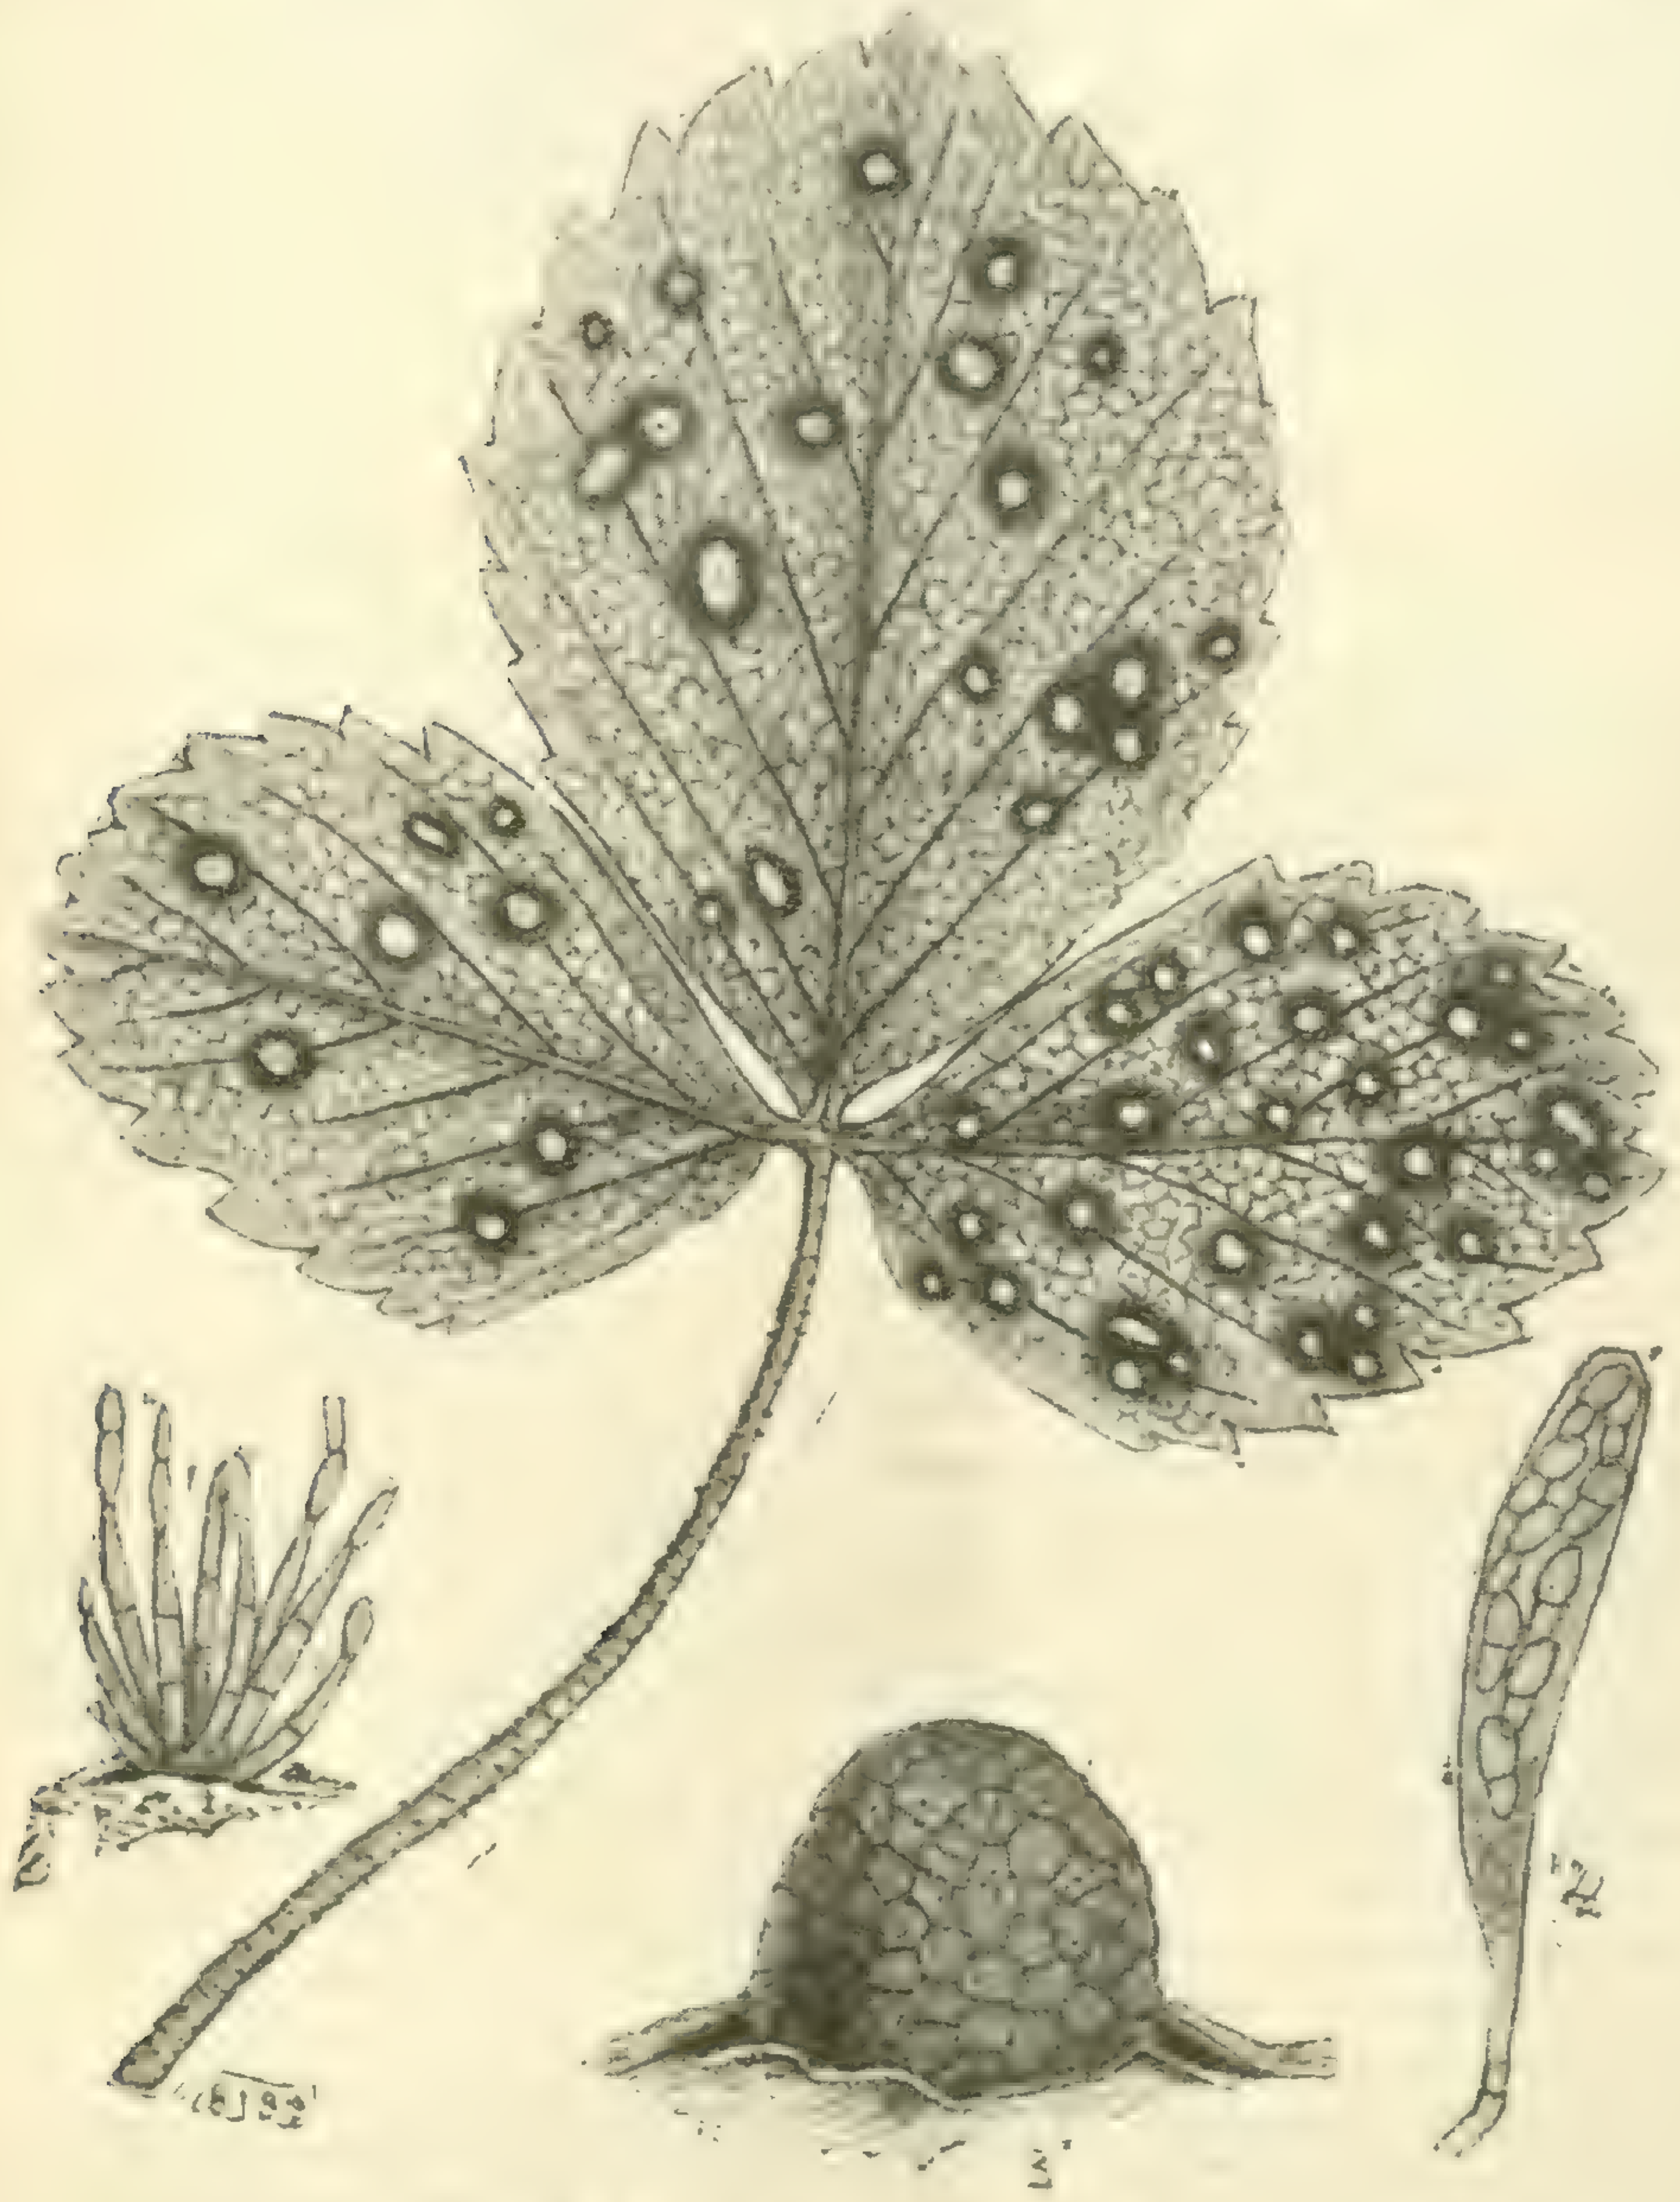
It has often struck me in this connection that the art of raising ferns from spores is peculiarly fitted for ladies. The whole process involves such a nicety of manipulation up to the point of potting the results, that it is a pity the gentle sex are practically strangers to it. This, of course, is a matter which the beginner can only view from afar, though it is, in fact, very simple. Take a shallow pan, well drained and filled with fern compost to within half an inch of the rim. So far so good, but, although we may rub this soil through our fingers, and take every precaution to eliminate anything which may interfere with the development of the tiny ferns, that soil is full of potential life, eggs of insects, seeds of plants, spores of fungi, and even tiny worms, are all ready to avail themselves of your cultural care, and act the cuckoo to your unfledged ferns. Place, therefore, a small piece of paper on the soil, and pour boiling water over it until the pan burns your fingers, the hotter the pan becomes the better, as it is astonishing what heat some of the fern foes survive. Now let it cool, and cover the pan with a piece of glass to prevent the intrusion of foreign germs and spores.

Meanwhile, the fern fronds from which you purpose sowing will have been lying alone between two sheets of glazed paper for a couple of days, and probably when lifted will have shed their spores thickly enough to form a light brown picture of itself. Scrape a little, the merest pinch, of this brown powder, and put it under a microscope. Wonderful! millions and millions of little brown semi-translucent oval bodies present themselves, scattered over the field of view. These are the spores, and as your little pan is obviously incapable of growing millions of ferns—and every spore is fully capable of yielding one fern, and possibly more—you learn, as a lesson from the sight, that a very small pinch will suffice, their sowing being indeed a condition of success. In a few weeks a green blush will spread over the face of the soil in the pan, and shortly resolve itself into a dense multitude of little scales, all facing the light. These scales go on growing until as large as herring-scales, by which time, unless your sowing has been an extraordinarily thin one, they will overlap each other so thickly that pricking-out is necessary to enable them to proceed. Here comes in the need for delicate handling. Prepare other pans as before, scalding and all, and with the point of a penknife pick out small patches the size of peas and insert them in the new compost an inch apart, just pressing them into little depressions so that they are [illegible] the soil. This done, they go ahead in fine style, and spread out so as nearly to fill the inch spaces. Then the transformation scene begins, and here, there, and yonder we shall begin to see the little ferns [illegible] up among the scales which have generated them: and if we be [illegible] and hope for new varieties, we can now start fern hunting at home [illegible] heart's content, for in pans of ferns raised from varieties the chances of new forms are very great. The next step is potting on, and the next, possibly, the renting of a few acres of land to accommodate your [illegible] your bay-windows facing the north only affording space for them.

CHAS. T. DRUERY, F.L.S.

STRAWBERRY LEAF SPOT.

THE strawberry leaf spot (*Sphærella Fragariæ*, Tul.) is a very destructive and widespread disease, occurring wherever the strawberry is cultivated; it is also met with on the leaves of wild strawberries, and from thence probably often passes on to the cultivated varieties. The leaves are the parts attacked by the fungus, the earliest sign of its presence being indicated by the appearance of scattered minute dark-red spots on the upper surface of the leaf. These spots as a rule rapidly increase in number, and also in size, adjoining spots often growing into each other, and forming larger, irregularly shaped blotches. As the spots increase in size, the central portion of each becomes grey or whitish, and is surrounded by a narrow dark-red ring. When the fungus has reached this stage of development, examination with a pocket lens shows the pale central portion of the spot to be sprinkled with very minute white tufts. Each of these tufts is composed of a bundle of very delicate white threads, or *hyphæ*, each of which bears an exceedingly minute reproductive body, or *conidium*, at its tip. When quite ripe the conidia become free, and are then carried by wind, rain, insects, or very frequently by watering or spraying, on to other strawberry leaves, where, if the surface of the leaf is damp with dew or rain, they germinate at once, enter the tissues of the leaf, and soon give origin to a new disease spot. As the conidia are produced in immense numbers, and in rapid succession, the disease spreads very quickly in the case of plants growing near to each other, unless preventive measures are adopted.



DISEASED STRAWBERRY LEAF.

FIG. 1. A diseased strawberry leaf; natural size.
FIG. 2. One of the minute white tufts of the first, or conidial form of fruit; × 400.
FIG. 3. One of the minute black raised points forming the second, or ascigerous form of fruit; × 100.
FIG. 4. A large cell or ascus, containing eight spores in its interior. Many of these asci are produced in the interior of an ascigerous fruit; × 400.

This conidial condition of the disease, which continues in vigorous growth throughout the season, was at one time considered to be an independent fungus, called *Ramularia Tulasnei*. Towards the end of the season, numerous very minute black raised points appear on the diseased leaves; these represent the second form of fruit produced by the fungus, each point being a fruit of complex structure, containing in its interior numerous spores or germinating bodies. These spores remain in an unchanged condition until the following spring, when they germinate and inoculate the young strawberry leaves, giving origin to the first or conidial form of the fungus. Another form of reproduction, which, like the spores, also serves to tide the fungus over the winter season, consists of minute black aggregations of the mycelium of the fungus, called *sclerotia*, which are formed in the tissues of the decaying leaves. These also remain on the ground unchanged until the succeeding spring, when they produce a crop of conidia, some of which find their way on to the surface of the young strawberry leaves and commence the disease afresh.

If the leaves of the strawberry are badly diseased, a good crop of fruit cannot be properly matured; furthermore, plants that have been seriously attacked by the disease, especially if the second crop of leaves, which appear after the fruiting season, is injured, afterwards remain weak, and as a rule are not worth preserving. Repeated experiments, both in this country and in the United States, have clearly proved that the disease can be held in check by the use of Bordeaux mixture. The plants should be sprayed with a dilute solution when the leaves are beginning to expand, and again at intervals if the fungus shows itself. It is most important that the plants should be sprayed after the fruit is gathered, so as to protect the second crop of leaves, as the vigour of the plants, and consequently the quantity and quality of fruit produced on the following season, depends to a very great extent on the amount of material accumulated by these leaves.

All diseased and dead leaves should be raked together and burned, so as to guard against infection the following spring; for although the leaves, if allowed to remain on the ground, would probably decay and disappear during the winter, yet the fungus fruit and sclerotia present in their tissues would not decay, but remain on the ground, and germinate in the spring, when some of the conidea produced would almost certainly find their way on to the surface of the young leaves, and thus commence the disease.

G. MASSEE.

THE AURICULA.

THE genus primula may be said to have held a levée of its admirers on the occasion of the recent exhibition of the National Auricula Society Though the improved modern forms of P. auricula were mainly represented, other species and sub-varieties were well to the fore, and found their admirers. It is well such an exhibition be held annually, and the Royal Horticultural Society is to be congratulated on encouraging the holding of such a display. Some of the best-known species and varieties of primula were seen in P. intermedia, unusually fine in character as shown by Mr. J. Douglas; the delightful P. verticillata, P. obconica; the charming ever-blooming P. floribunda; some varieties of P. Sieboldi; a fine form of P. pubescens, in the Bookham collection; P. japonica, &c., also the primrose, both double and single, with the bolder polyanthus. It was a liberal feast of spring flowers, relished by a large company. It was the florist's auricula, however, which held the field; his green, grey, and white edges, and striking selfs, with brilliant alpines of many shades and pleasing combinations of colours, and the grotesque and striking nondescripts, conveniently denominated "fancies." Those interested in the fascinating flower saw it in numbers, but not at its best. There was little of that superb finish sometimes seen. Nature had not been in a benignant mood; cold winds, frost, and drought induced roughness; the incidence of the weather was too powerful for the best endeavours of the florist, and he was beaten in the conflict. He did his best against unequal odds, and it was gratifying that he did so well. A genial season is required to impart finish to the flowers; it was uncongenial, hence comparative failure. Yet the exhibition was full of interest, as reported in these columns, notwithstanding. The auricula is a perennial, but its life is one of limited duration. "An individual plant may maintain its vigour and blooming powers for a few years, and it is found in experience that plants of some varieties are slower in coming to maturity, and longer lived than those of others. In a dozen plants of any one variety no two may live for exactly the same time, or during their life be in corresponding health. It is impossible to define the life-term of this plant by the duration of a single individual. It may eventually so break into several heads that which of them is the real original no one can say. It may give off increase, and in favour of strong young plants, the parents may have been thrown aside when comparatively worn out; or in its evident old age the plant may have been cut over, and the much reduced and narrowed head induced to go on afresh in restored strength for a time. Some varieties die young; our leading raisers have had experience of young seedling beauties that were short-lived, sometimes to the dying of the seed plant without issue." Such is the testimony of one who knows the auricula well.

Some varieties of show auriculas are longer lived than others, and all the care exercised in the culture of the latter cannot keep them in vigour beyond a limited time Probably a variety cannot be expected to last longer than six years at the outside, hence, then, the necessity for obtaining young stock, so that existence may be secured. This is the way Nature suggests for maintaining a collection in all possible completeness. Some sorts give off increase much more freely than others, while others will form an offset quite at lengthened intervals. Occasionally it is necessary to behead a plant to obtain increases, making a cutting of the top and causing the beheaded stem to break into growth. It may happen that all the care bestowed upon a particular variety will not induce it to make vigorous development, but change has been known to conduce to this result, either by sending the plant to some brother florist to nurse to convalescence, or by exchange of the same variety from a distant part. Further, to maintain the auricula in the characteristic attributes which commend it to the enthusiastic florist, the raising of fresh varieties from seed is vital to its existence. Yet some varieties have been in cultivation for half a century or more, and among them a few of the best. Yet it is a fact that in the course of years they surely, if slowly, wear out, not coming in character so constant or so grand as they used to do. They become more difficult to keep, and pass out of cultivation. There are always growers who cherish the favourites of bygone times, and when the evening of a long day comes at last for those which have become sacred by long association parting brings sore regret. Old varieties will no more live for ever than human beings; and, on the other hand, no new variety has been raised which cannot be surpassed. It is as sure as possible that flowers more fixed and richer in qualities of recognised excellence than the former ones can be raised; and that our improvements will be improved upon, if only men follow who will care to give the love, and thought, and time required to the work.

R. D.

CHAT ABOUT HARDY FRUITS.

EVERY department of a garden possesses rapidly increasing attractions at this time of year, but perhaps none is so full of interest as that devoted to hardy fruits. The flowering period is the season of promise and hope. When our trees are advancing to an abundant blossoming, we have the prospect before us of a later stage in their career when they may be laden with welcome fruits. We have besides, however, the present enjoyment of their beauties; and of all deciduous shrubs and trees in cultivation few can rival and none excel the floral charms of our cherries, plums, pears, and apples in a favourable season. Many writers have advocated planting a few specimens of the best varieties in the ornamental portions of gardens; some amateurs and practitioners have really done this with most satisfactory results, but it is not a plan that can be carried out under all conditions and circumstances. Still in shrubberies forming boundaries to lawns I have seen select fruit trees introduced with admirable effect, short-lived as their charms may be.

Fruit growers may experience all the pleasures of the most advanced æsthetic person in observing the masses of snowy or rose-tinted blossoms adorning their trees, but the economic aspect influences their meditations even more strongly. The satisfaction derived from contemplating an abundant display of flowers is greatly moderated, when sunny days followed by clear nights and sharp frosts, at the blossoming period threaten the partial or entire destruction of all hope as to fruit crops. Much will then depend upon the moisture or aridity of the atmosphere, and within the past week or two the frosts experienced would no doubt have proved more injurious had the air been less dry. Fortunately in a large plantation under my care, and in others that I have seen in the district where plums and damsons have been flowering with exceptional freedom, little damage has been observed, although the night temperature has fallen six degrees below freezing point (Faherenheit) on several occasions. Pears also seem to be safe up to the present time; apples are scarcely sufficiently advanced to suffer, and gooseberries have so far escaped the injury that so seriously reduced the crop last year. But the bulk of our apples have yet to flower; so that there is much anxiety yet in store for us before the ordeal is passed.

The greatest trouble to the naturally energetic is to feel powerless to avert an approaching evil; but the question has often occurred to me whether we could not adopt some workable system of protecting the blossom of fruit trees in the open. In the case of large standard or orchard trees it is impracticable to employ any material as a covering, though in plantations of dwarf trees and bush fruits it is quite possible, the only difficulties being the expense incurred in material and labour. For large plantations this, however, is quite prohibitive, as though a very slight substance in the way of netting, tiffany, or canvas will suffice to check the radiation, yet to cover an acre effectively with protective material secured to posts at suitable distances would cost at least £20. As it is only exposed for a short time the material might last for five years, but there is always the risk of storms not only destroying such an arrangement, but seriously damaging the trees at the same time. Perhaps, therefore, it is not surprising that little has been done in this direction beyond protecting small plots in gardens or compact plantations of bush fruits.

Another method of affording protection from frost has been extensively tried in France and the United States, namely, "smoking," or "smudging" as it is termed. This has given good results, and the cost is not prohibitive if well managed; it therefore might be worthy of more trials than the plan has yet had in Britain. The principle upon which its success depends is that a dense smoke diffused over a plantation checks the radiation, and consequently reduces the danger of sharp frosts. That risks can be thus lessened is beyond question, but it is necessary in the first place that the plantation occupies a level piece of land, not a slope or the bottom of a valley; secondly, the atmosphere should be calm, but this usually is the case when severe frosts are imminent, and obviously the practice would be of little service in a strong wind; thirdly, some substance must be used that will produce a dense smoke slowly and continuously, in order that it may be evenly diffused.

In the French vineyards several patent compositions are in general use, and syndicates have been formed amongst neighbouring growers, so that combined action and mutual protection may be afforded. By this means the cost has been reduced to a few pence per acre, and the results have given general satisfaction. Any substance that will consume slowly and emit a thick, heavy smoke will answer the purpose; damp wood mixed with partly-dried grass, damp hay, straw, and leaves have been employed, while common petroleum, coal-gas oils, tar, and sawdust have been used similarly. Sawdust and tar make a good mixture in the proportion by bulk of three or four parts of sawdust to one of tar, but damp wood or rubbish generally is convenient for many, though it may not be so effective. One gallon of tar and three times the quantity of sawdust will, if properly mixed and attended provide a dense smoke for eight hours, small quantities being ignited in succession. The actual cost of the material does not exceed 2d., and there is only the labour to consider, but this is not serious, as a man or a boy can attend to a large number. The burning material must not be placed near enough to trees to cause injury by the heat produced, and the "smudges" need constant attention in order that they may not burn too quickly, spraying them with water if necessary. This is a double advantage, for while checking the consumption of the fuel, the evaporation of water assists in lessening the radiation; indeed, a trial has been proposed of the effects of evaporating water extensively to arrest radiation and secure immunity from frost.

When the atmosphere is very dry the lowest temperatures are usually recorded, yet I think it is the general experience of growers, as it certainly is mine, that much less injury to blossom results than when the air is moist. In other words, when the air is partly saturated a frost of two or three degrees will do more harm than five or six degrees under drier conditions. This statement seems to be in conflict with the suggestion at the end of the preceding paragraph, but they are not so much opposed as appears at first sight. In the evaporation of water heat is absorbed, and in the condensation of such vapour the heat is again liberated; it is therefore possible to evaporate water by artificial means in sufficient quantities that the vapour, being condensed on cold surfaces, may release enough heat to prevent the temperature falling below freezing point within a limited area. Then we have the protection sought; but if frost occurs at all, it appears that the danger is increased by the moisture present. There is the question to consider, too, whether the greatest injury to blossom results from the actual freezing or sudden thawing. When frosty nights are followed by clear, sunny mornings, the injury to fruit blossom is generally greatest on the eastern sides of plantations, if fully exposed to the sun, and I have observed it also on the eastern sides of individual trees. At such times the presence of moisture may be an advantage in preventing rapid thawing, just as we syringe frozen plants in pots and shade them from the sun rays until the thawing has been gradually effected.

Many have advocated the extensive planting of the Cherry Plum, or Myrobalan (*Prunus cerasifera*), for hedges, a purpose for which its rapid growth undoubtedly renders it suitable. If planted thickly, it forms a dense hedge in a few years, and though not so effectual a protection from cattle as thorn, it yet suffices for all ordinary boundaries, and is a first-rate wind-break. Unfortunately, its precocious leafing renders it liable to severe injury, and this year the leaves were expanding in January, the flowers also being open in February, and the result is that nearly the whole of the foliage has been destroyed by frost. This does not occur every season, but the flowers rarely escape some injury. The myrobalan in this respect resembles the Japanese plums, that are so much in favour in America. Here the flowers are produced so early that in the few seasons I have tried them they have all been destroyed by frosts. A. M.

DWARFED CHRYSANTHEMUMS.

IN the manipulation of chrysanthemums with a view to secure a dwarf bushy growth, it has apparently of late been considered a modern practice to strike cuttings in May and June. But will you permit me to state that this method has been known and adopted to my knowledge for more than half a century? Consequently the sun is not diffusing its life-giving powers on any new innovation or up-to-date practice. If the present generation of cultivators were familiar with the modes of cultivation practised by those designated the "old school" of gardeners they would understand that the practice of striking the cuttings, as has been advised, to secure good healthy, dwarf plants, has been in force ever since the Autumn Queen was introduced into this country.

I reported a paper read on the subject in 1846, and the report appeared in the *Florist Journal*, at that time conducted by my old highly-esteemed friend, the late Mr. Robert Piant. Herein it was advocated that May, and even later, where dwarf plants was the wished-for object, was the very best time for successfully striking cuttings for that purpose. It is recorded in the early writings that the Chinese even adopted the practice, as also the thinning the buds, so as to obtain large flowers; and this practice was thoroughly advocated in the paper alluded to and by one of the members present on that occasion in speaking to the subject. The report as it then appeared I have still in my possession.

There were other methods of propagating the chrysanthemum. Some amateurs especially used to increase their stock by suckers or by dividing the plants; others by layering. I well remember that in August, 1843, being thus engaged to prepare a large stock of plants for conservatory decoration, and very fine plants they made, blooming most profusely during the whole of the dull months of autumn and early winter. The stock plants had been specially prepared by being planted in a fine open piece of ground in a sunny situation. I am now referring to the preparation of plants for a large winter-garden-like conservatory. It should be understood, however, that at the period I refer to garden appliances and glasshouses were in many respects like angel's visits, comparatively "few and far between." So the "old school" gardener had to husband his resources in a very methodical manner, hence those with small accommodation for flowering plants during the autumnal months were in a measure compelled to produce plants as small as possibly convenient, so as not to injure specimens of a more permanent and valuable description.

Very many, as well as the writer, made it an annual practice to strike cuttings of chrysanthemums after the showing of the bloom buds on the growths. These made interesting and very useful plants for mixing with primulas, &c., and added considerably to the cheerfulness of the greenhouse and conservatory. At the time I refer to, gardeners were minus the advantages of the present generation, but I have been privileged to live in the old as well as the new horticultural times, and have practically seen the many and marvellous changes and advancements in the healthy and the mind-invigorating science of horticulture and floriculture.

Lewisham. GEORGE FRY.

Exorchorda grandiflora.—This shrub is flowering very finely again this season, and though it was very much checked by the frost in April, it has braved the weather and been a mass of bloom for some time past; indeed, it is the most conspicuous hardy shrub now in bloom. It will grow in almost any soil or situation; we have it in sunny positions as well as north and west aspects, and thus obtain a succession of bloom which is most useful; in some cases the shrub is not growing in more than nine inches of soil. Planting should be done in October, and if the weather prove dry give a good soaking of water after planting.—W. A. COOK, *Compton Basset.*

MEMORIES OF BRUGES.

BRUGES, the capital of the Belgian province of West Flanders, is an interesting old city, but nevertheless one that retains but a remnant of the glory it possessed in the fourteenth century, when it was the chief commercial centre of Europe. It is only seven miles and a half from the coast, and connected with it by broad and deep canals that are available for vessels of considerable size. With many of its former glories the commercial fame of the City of Bridges has largely passed away, and little seems to have been done to make good the loss by modern methods, as the observation that about one quarter of its population of over 48,000 persons are paupers, will prove. The city wears a sleepy air, and one could imagine oneself dropped back suddenly into mediæval times, but for the dress of the people. You see more sabots at Bruges than at Ghent, and more folks dressed in the older-fashioned provincial style of tall peaked cap and ample blouse for the men, and ample head-gear (or entire lack of any for occasional contrast) with coloured shawls for the women. Bruges contemplates the height from which she has fallen, while other of the old Flemish cities have to a large extent become rejuvenated.

The *portes*, or gateways, of the city are well preserved, and with the ramparts serve to remind us that Bruges once had a great trade to guard, and guarded it well. These old gateways are highly picturesque, and are mostly situated at the end of a canal bridge. Not far from the fine railway station is the Gothic cathedral of St. Saveur; as compared with the cathedral at Antwerp it is a poor affair exteriorly, but inside it is amply proportioned and beautifully decorated, while it contains paintings by such celebrated artists as Van Dost, Jean Bethune, and Dierick Bouts. The church of Notre Dame, with a spire three hundred and ninety-five feet high, is a conspicuous building of some beauty, and said to contain many very fine works of art. The ancient palace of the Courts of Flanders has practically disappeared, but Bruges contains several museums, library, academy, and Palais de Justice, not forgetting the celebrated Belfry, commenced in 1282, and rising to a height of three hundred and fifty-two feet; it contains a grand set of chimes that are only to be heard to full advantage on certain days of the week. Everyone has heard that—

> "In the market place of Bruges,
> Stands the Belfry, old and brown;
> Thrice consumed and thrice rebuilded,
> It watches o'er the town."

If the city of Bruges is now no longer a great centre or silks, linen and woollen goods, it yet has another string to its bow. This string is its increasing horticultural trade, for both inside, but more extensively outside, the city boundaries, nurseries are increasing in number and extent, and all seem to be flourishing. Many of these firms do a very large export trade and employ a large number of men and women; others do an almost purely market business in plants and cut flowers of a choice character. Some grow liliums extensively, others orchids; while a few devote their attention mostly to the seed trade and a more local business. The Bruges nurseries seem to be largely grouped along the south and west sides of the city, and one comes upon them immediately after passing out of either the Porte d'Ostende, the Porte de Gand, the Hazelporte, or other of the gateways towards the south and south-west.

Arrived at Bruges station, you will, if horticulturally inclined, turn sharp to the left after giving up your ticket, and, crossing the railway that leads to Ostend, take a direction almost due south. In a few minutes the pedestrian will be outside the city and clear of the cobble-stone and paving that spoil both boots and temper; here you emerge upon a country road, lined with trees and margined with ditches. Passing a wayside farrier's shop, and strings of farm and wood carts, drawn by stocky Flemish horses, open country appears an either hand, but in the near distance you catch sight of a broad expanse of glass roofing that tells of some enterprising nurseryman. In one point, at least, the proprietor differs from the nurserymen around him—he does not paint his name in black letters across the whitened front of the most prominent building in the establishment. Who then is the great unknown? Unknown!! Why, this is the continental branch of the St. Albans nurseries of Messrs. F. Sander and Co.

Some member of the firm is sure to be at the Bruges establishment, and during the recent Ghent Exhibition it was as much as Mr. F. Sander, his three sons, Mr. Godseff, and several foremen could do to pilot parties of visitors round the establishment, and get through the usual business. Already a hundred houses, all built of pitch pine, have been erected, and all are well stocked; the houses vary in length, but many of them are very long, in three divisions, and running into a long corridor at one end, the corrider serving as potting shed and storage for imported orchids, &c. The nursery has an area of twenty-five acres; more than a third is covered with glass houses, and still others are in course of construction, so that so far as glass is concerned this establishment bids fair to exceed in extent any other of its kind on the Continent.

The brickwork is composed of small and very dense red bricks, and presents a very neat appearance. The woodwork, as previously noted, is pitch pine, so that both durability and smart appearance have been secured; the roofs are light, that is, the glass is wide throughout, so that all possible light is admitted. In the long orchid houses the staging is mostly iron, and double; on the lower iron stage a layer of farmyard manure is placed, and over this is arranged a light and open wooden staging on which the plants rest. Rough tobacco is also placed in quantity, here and there, where heat and moisture can extract from it its insecticidal properties for the benefit of the plants. Shading is almost entirely done by means of the wooden lath blinds so popular and extensively used in continental establishments; this shading breaks up and diffuses the sunbeams, and yet it does not seem to materially lessen the amount of light that would otherwise pass through.

Grouped in the small glass porches that cover the entrances to the ranges comprising the first block of houses, azaleas of all the newer and finer kinds were recently arranged, and these being covered with blooms made a dazzling display. The azalea business is one upon which the firm has embarked with a will, and already they find the demand is greater than the supply. Huge blocks of ridge-and-furrow houses contained thrifty specimens of these Indian azaleas, but these plants have, ere this, been planted in their summer quarters in a compost of oak-leaf mould and the natural sandy soil of the district. Thirty houses are devoted to azaleas, and one of the prettiest sights to those fond of plant raising was the two hundred thousand azalea stocks for subsequent grafting. These figures, together with the statement that here there are about six thousand seedling azaleas, almost all as yet unflowered, will give the reader some idea of the extent of azalea culture at the Sanderian establishment at Bruges. There are tiny azaleas, medium sized and large specimen azaleas, azaleas on the floors, stages, and on shelves close up to the roof; azaleas in pots and azaleas planted out, and by far the greater number were planted on the stages, though since transferred to open quarters for the summer. Vervaeneana, Deustche Perle, Sigismund Rucker, Simon Mardner, Roi des Belges, Cérès, Empress of India, Comte Oswald de Kerchove, and Borsig, are among the most extensively cultivated varieties. These, and very many other kinds being represented by fine stocks that should be first-rate for next season's flowering.

Sweet Bays are not less numerous here than at other Belgian nurseries of note; there are long rows of healthy well-developed specimens, both pyramid and standard shaped, and in many sizes. The wonder is how the enormous stocks of bays can be stored each autumn in the big sheds where they winter. Big bays do not grow up in a night, like Jonah's gourd, but have to be grown for many years ere they reach a profitable size. Several houses are devoted to camellias, and the collection is extensive in its variety. Araucaria excelsa is cultivated in such quantities that quoting figures would be but to bring upon myself the indignation of those who have not seen the stocks here, and who would imagine my signature should be "Longbow," rather than what it is.

Palms arrest the attention by reason of their abundance, cleanliness, and general health. There are hundreds of thousands of them, varying in size from the midget, in a thumb pot, to big waving specimens in large pots or tubs. It is quite unnecessary to pass down one side and up the other in these palm-houses, for those that meet the gaze upon opening the door form a sample of the general contents, so a walk of some hundred and thirty yards is saved—many of the houses are two hundred feet long. The Date Palms, Phœnix rupicola and P. reclinata; Cocoa-nut Palms, such as the towering Cocos plumosus and the beautiful C. Weddeliana; fan palms, such as Latania borbonica and Licuala grandis; Kentias, chiefly K. Belmoreana, K. Forsteriana, and the new and elegant geonoma-like K. Sanderiana; Cabbage Palms, notably Areca Baueri and A. lutescens; and the Chinese Rhapis flabelliformis, and its Japanese relative, R. humilis—these are the principal palms seen at this Bruges nursery, though not a few other sorts are grown, but in lesser quantities.

While selective culture is the chief order at this modern nursery, yet collection has not been altogether forgotten, and the variety of plants to be seen is greater than at many another Belgian establishment. Here are to be seen large batches of the popular Pandanus Veitchi and the once-common P. utilis, of Vriesia tessellata and Eucharis Sanderiana, Dracæna Sanderiana and the spreading D. Godseffiana, D. indivisa and Ficus elastica, Saintpaulia ionantha, gloxinias and foliage begonias, dasylirions and anthuriums, Myrsiphyllum asparagoides and green and variegated aspidistras, nepenthes and bertolonias—and so one might continue. An enumeration of all the plants grown here would prove interesting, but space forbids. Everything, however, is on a large scale, and the houses neat and clean, and the plants as healthy and vigorous as even the proprietor could wish. The ground not covered by glass-houses, offices, bay-sheds, stables, packing-sheds, &c., is being brought under cultivation; as indicated, a very large area is necessary for the azaleas during summer. Another large slice is devoted to the choicer liliums, including half a million of the pure white Lilium speciosum Krætzeri.

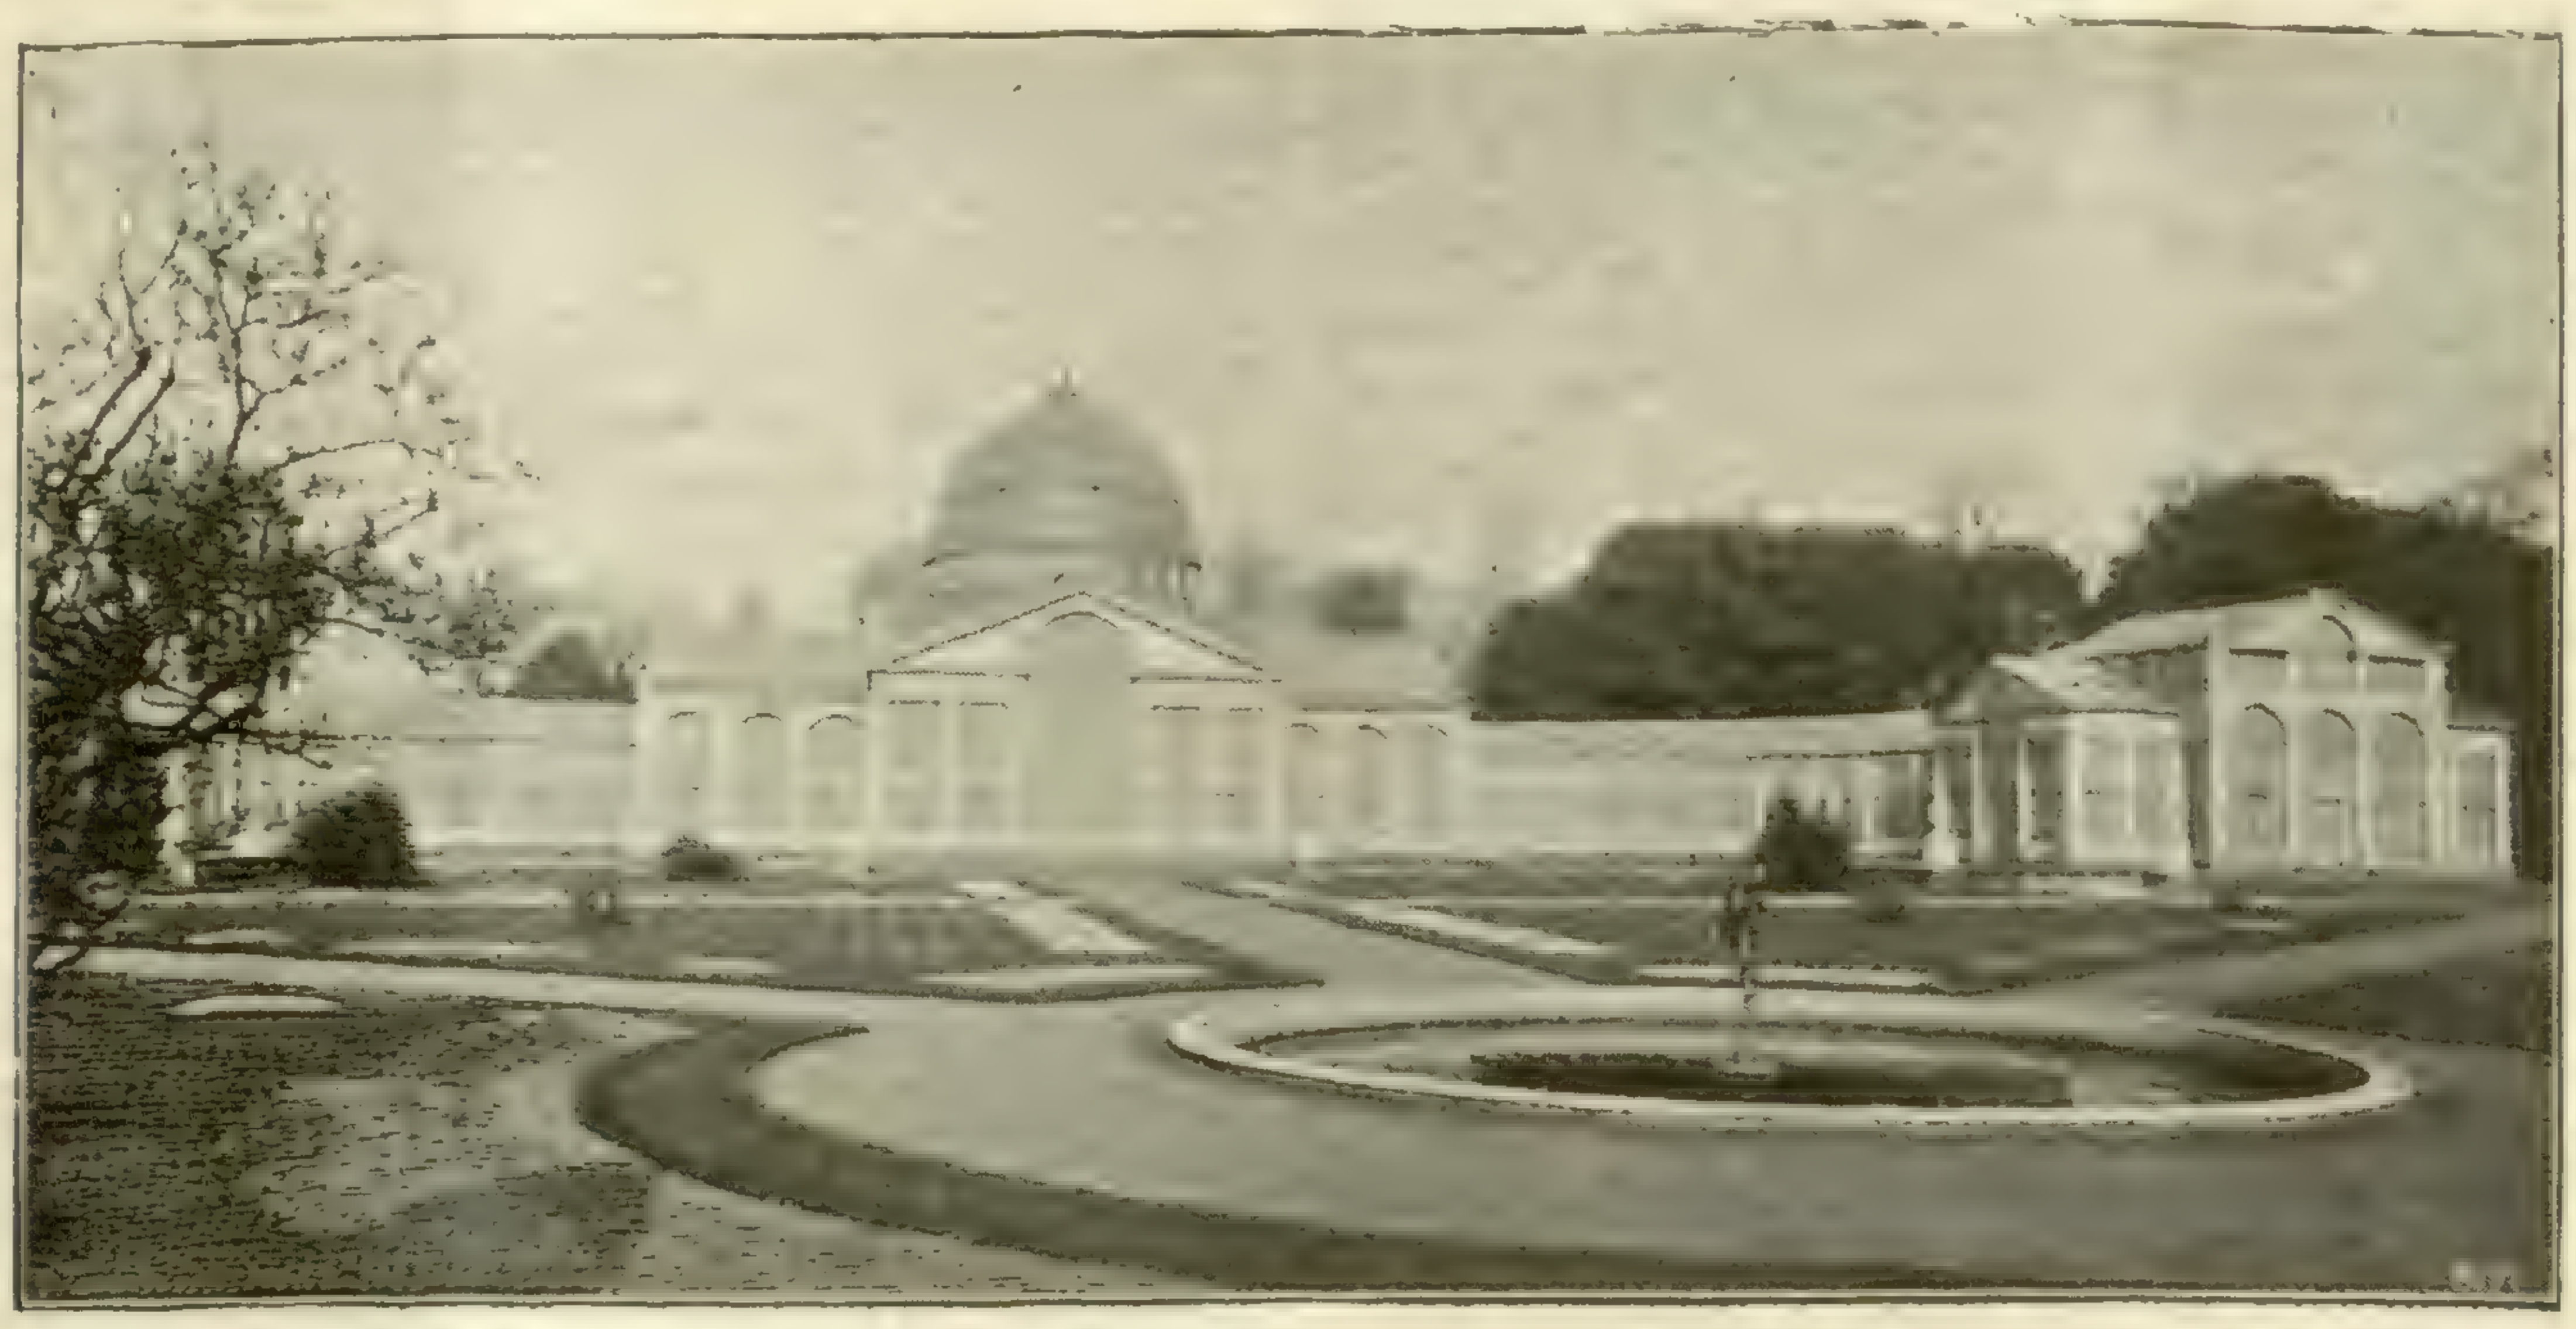
One naturally expects to see orchids a prominent feature wherever the Messrs. Sander go, and certainly the visitor to Bruges will not be disappointed. Here, as at St. Albans, the better known and most popular sorts are grown in quantity sufficient to fill half a house, or it may be two or three houses, and there can be no doubt that when grown in bulk and treated exactly in accordance with requirements, orchids of almost all kinds do their best. The first range covers Odontoglossum grande and Lælia anceps, many thousands of each. Then follow odontoglossums innumerable, some of them pretty little plants establishing themselves contentedly in leafsoil and sphagnum; others sturdy specimens in larger receptacles, and many of them carrying long graceful spikes of handsome blooms. O. crispum, O. luteo-purpureum, O. Halli, O. Wilckeanum, O. Ruckerianum, O. sceptrum, O. Rossi majus, O. Cervantesi, O. Harryanum, O. odoratum, and O. cirrhosum were those most in evidence by reason of their flower spikes, and here and there these were grouped effectively with begonias and other foliage plants. There are big colonies of Lælia purpurata and the lovely cattleya Schroderæ, the latter flowering freely and the former bristling with fat flower sheaths. There appeared to be enough of Lælia purpurata to fill one of the tents at the Temple show, and the majority were first-rate specimens in pans twelve by twenty inches across. All the cattleyas of commercial value are here to be found, from the labiate forms to the tall stemmed guttata section, from the striking C. Acklandiæ to the fragrant C. citrina.

There are crowds of Lycaste Skinnerion, under and over the stages, all in good condition and mostly producing excellent flowers. Oncidum sarcodes and O. ampliatum majus, both very attractive orchids, naturally occupy much space, while the popular cypripediums occupy several houses. Miltonians must not pass unmentioned, nor the suspended ranks of Rodriguezias. The pretty Stenoglottis longifolia also deserves a notice, for it is one of the prettiest of cool orchids, and lasts a very long time in flower. Several houses are devoted to newly imported orchids, such as Odontoglossum crispum, Oncidium tigrinum, &c. Behind the principal blocks there is a small range of short houses and here are to be seen some of the choicest of orchids. A very fine example of Cypripedium drursi was staged along with other choice and rare cypripedes; there was the white C. bellatilum album, lots of the rarer hybrids and hundreds of tiny seedlings that have yet to make their mark; cross-breds having C. Curtisi, C. niveum, C. Roeblingianum, C. Lawrenceanum, C. insigne, and others for parents. Then this range also covers a small batch of odontoglossum seedlings, minute plants as yet, but still up and growing and exciting a good deal of speculation as to their ultimate accomplishments. Then there are seedling lælias, the result of carefully considered crossing, beautiful little toy-like plants in tiny thimble-like pots and each with its small celluloid label attached. Seedling cattleyas are also here, and epidendrums and dendrobes, with a few others of more or less importance, all, however, capable of surprising the hybridist by their superiority to anything of the kind yet seen, or by their exceeding beauty, utility or great worth. However careful the worker may be the results are not always in his hands, and sometimes nature shows in a most marked manner her disgust at the intermeddling of man while at others she rewards his ingenuity, care, and patience by a wonderful combination—such combinations as have from time to time appeared from the St. Albans establishment, and such as it is hoped will in future first display their graceful forms or exquisite colouring at the Bruges branch.

SERVATOR.

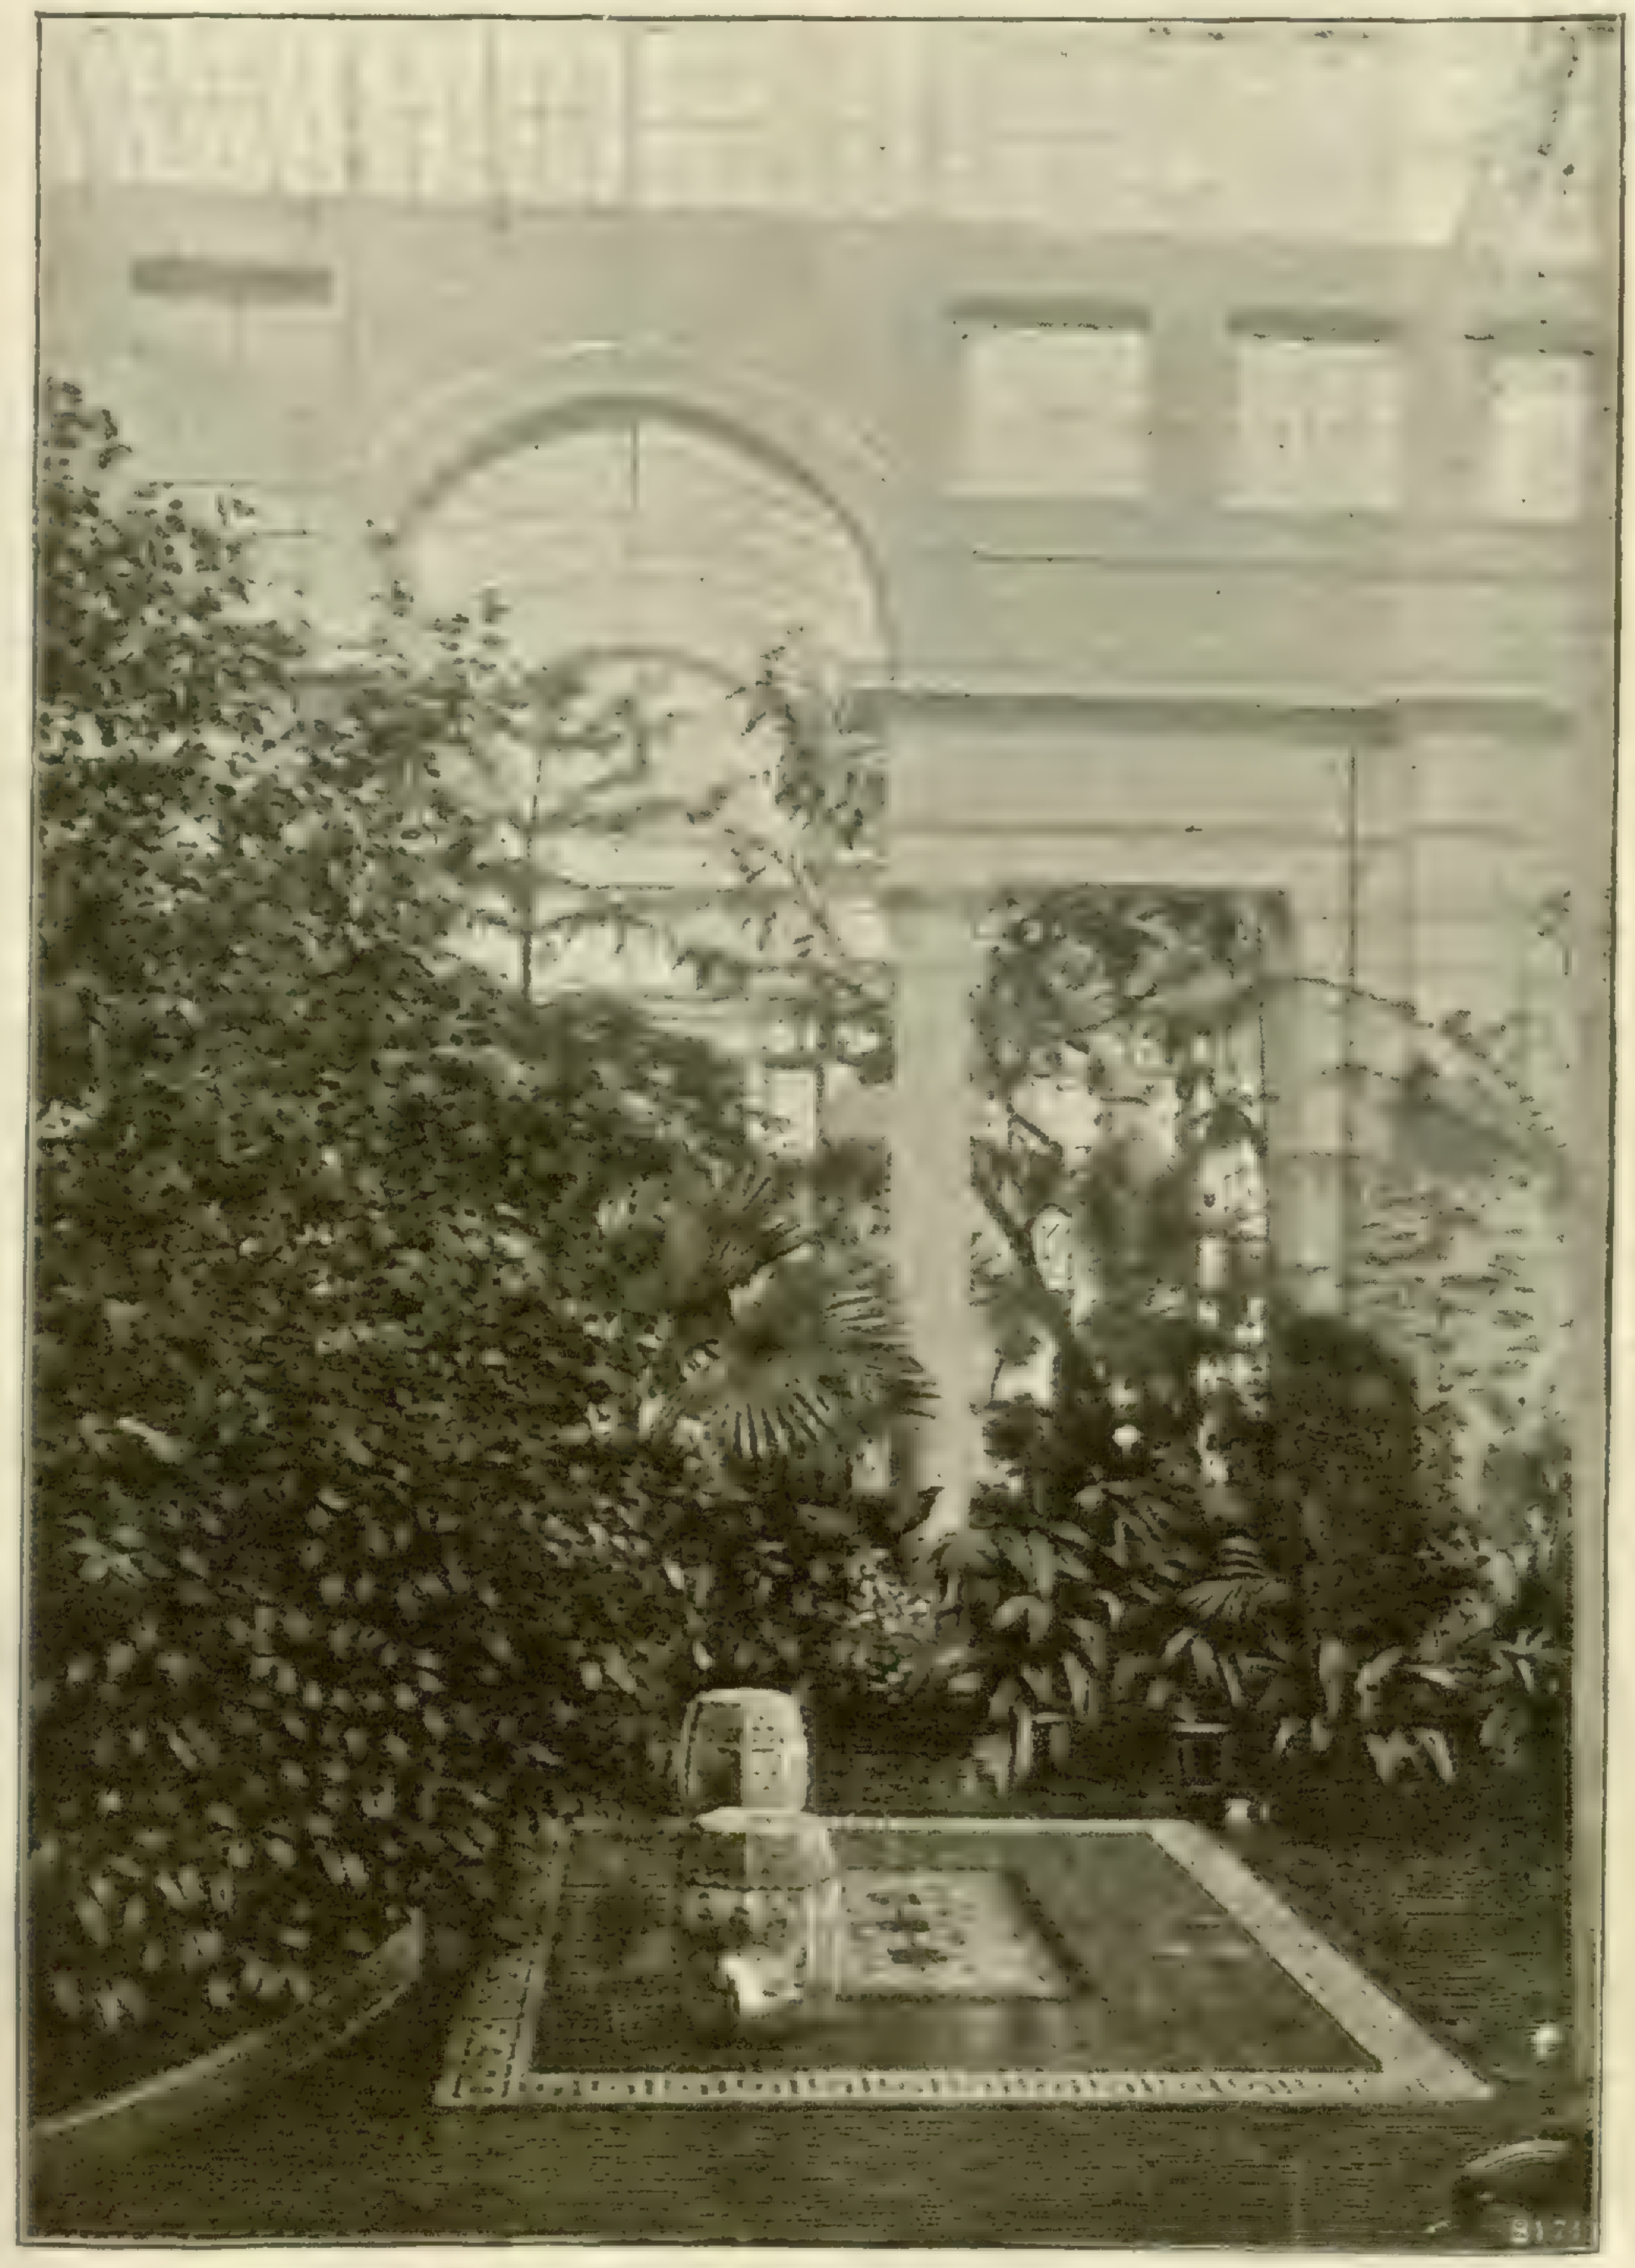
THE SYON CONSERVATORY.

CHIEF among the several features that have contributed to the well-deserved fame of the gardens of Syon House, the historic residence of Earl Percy, is the great conservatory, which has long been recognised as one of the most handsome of the plant structures erected in private gardens early in the century, and widely known for the highly interesting character of many of the plants that have found a suitable home within its walls. At one time this magnificent structure was largely devoted to plants of great botanical interest; at another a considerable proportion of its available area was occupied by splendidly developed specimen flowering and ornamental-leaved plants that made their mark at the public exhibitions and added to the lustre of the gardens. Then at a later period the specimens were superseded by a more varied collection of plants, and the structure became remarkable for the great beauty and interest of the displays annually produced in the sections devoted to plants grown in pots. The structure has since its completion about seventy years ago seen many changes in the character of the plants with which it has been embellished, and now, as the result of shifting fashion and a fuller appreciation of the uses of plant houses from a recreative point of view, it also has had to submit to a considerable modification in the arrangement of the interior, and a brief reference to the improvements that have been effected can hardly fail to be of general interest.



THE CONSERVATORY AT SYON.

The gardens at Syon, as in the case of the mansion, may be traced back for several hundred years, and it would appear that at the commencement of the present century they were considered to have become somewhat out of date, and to be in need of considerable alteration. However that may have been, improvements on a very extensive scale were commenced at Syon in 1825, and carried on during the next two or three years. The alterations and improvements were carried out under the direction of Mr. Forrest, who was one of the most successful garden architects of his day, and was held in high estimation by Mr. Loudon, who, in the fifth volume of the GARDENERS' MAGAZINE says, in reference to his ability, "As a garden architect we know of no man to be compared with Mr. Forrest. Among many examples in different parts of the country, we may refer, as a standing proof of his ability in that department of his profession, to the admirable range of forcing houses and pineries erected in the kitchen garden at Syon." The alterations included the rearrangement of the kitchen garden, and the erection of the long ranges of fruit and plant houses, from which at the present day Mr. Wythes annually obtains such enormous supplies of grapes, peaches, figs, melons, strawberries, forced vegetables, and cut flowers. The erection of the conservatory followed shortly after the completion of the forcing and fruit houses, and in the preparation of the plans of this structure Mr. Forrest had the assistance of Mr. Fowler, an architect of high standing in his profession, and it is probable that it was designed by Mr. Fowler in accordance with the ground and sectional plans prepared by Mr. Forrest. If this be so, Mr. Fowler is, of the two, deserving of the highest meed of praise, for, as originally designed, convenience of internal arrangement was not equal to the ornamental character of the exterior.



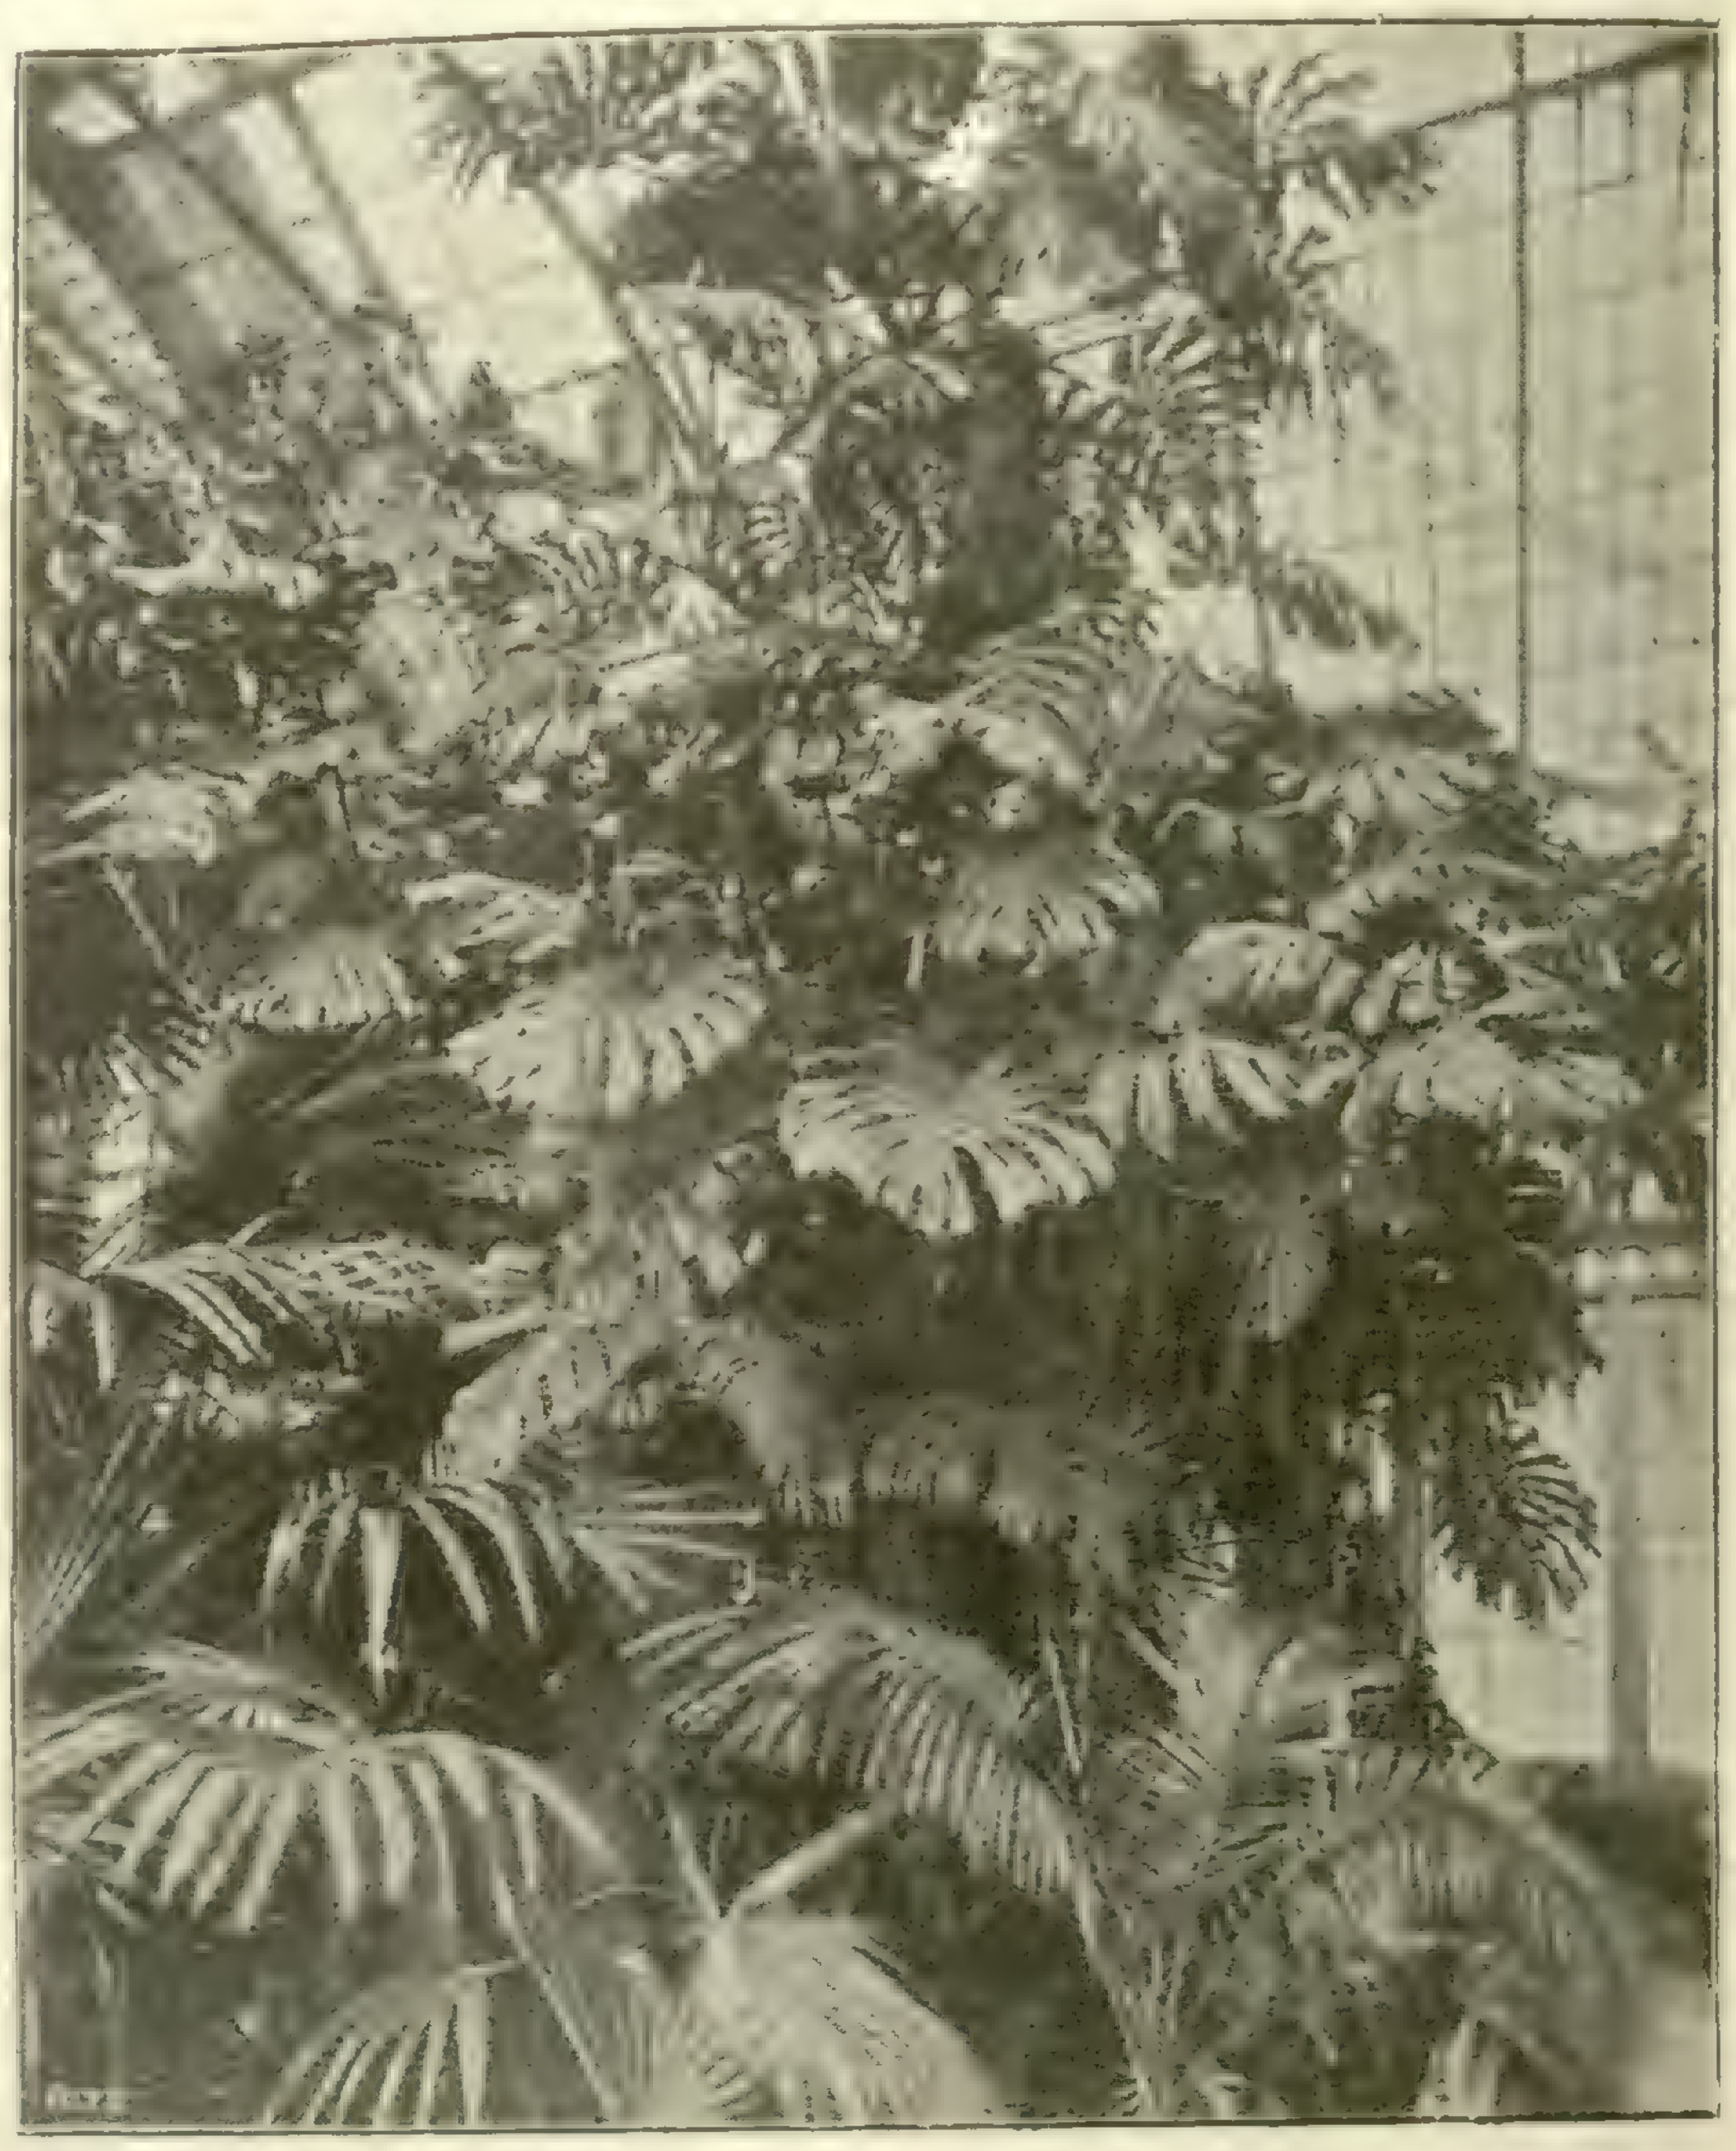
EAST WING, SYON CONSERVATORY.

The building forms the northern boundary of the geometrical flower garden, which occupies a somewhat secluded position a short distance from the northern side of the mansion, and, as shown in the illustration given herewith, it consists of a central compartment and two wings connected by corridor-like structures describing a rather sharp curve. It is three hundred and eighty feet long and the centre, has a length of about one hundred feet and a width of fifty feet, and the cupola or dome rises to a height of sixty feet. The two wings are each about sixty feet in length, forty feet in width, and about forty feet high, and the connecting portions of the building are about twenty feet wide and twenty-five feet high. As originally arranged the conservatory was divided into nine sections, and the corridor-like parts of the building were each divided into three, and in addition were fitted with high stages for the accommodation of plants in pots, and as those in charge had, in watering and giving other attentions to the occupants, to pass along under the stages and mount them by small openings here and there at the back, a more inconvenient arrangement could not well be conceived. The separation of the structure into so many parts rendered it difficult to exercise any considerable degree of taste in the disposition of the plants, and the opening and shutting of the numerous doors detracted materially from the enjoyment of visitors. Moreover, there was but one pathway through the portions connecting the wings with the main body, and as that was hardly wide enough for two persons to pass, considerable inconvenience was experienced, more especially on the occasion of garden parties, when there are between two and three thousand visitors in the grounds.

To obviate this inconvenience, and render the structure more thoroughly enjoyable, Earl Percy decided to have the whole of the glass divisions removed, and the staging abolished, and to have in the narrow sections a series of oblong beds along the centre, with broad paths on either side. These alterations, with others that were rendered necessary in giving effect to the wishes of the noble owner, have been in progress during the past two years, and now they are complete it can rapidly be seen how great is the improvement that has been effected. One of the most important of the improvements that have been made has been the rearrangement of the heating apparatus. Originally the structure was heated by steam, with the aid of upwards of two miles of piping. Steam was in due course superseded by hot water, but in accordance with the views that obtained when the hot water apparatus was fixed the pipes were placed so far below the level of the path that there was a great loss of heat at all times, and some difficulty in maintaining the requisite temperature in severe weather. The pipes have all been taken up and fixed above the level of the floor in accordance with the more correct views that now obtain with regard to the distribution of heat; but as a matter of course care has been taken to so arrange them that they are in no way obtrusive. In the past three sections were devoted to stove plants, but under the new scheme in the centre alone is a temperature adapted to the requirements of tropical vegetation maintained. A considerable part of the roof has been taken off and renewed, and this alone has been a work of considerable magnitude, as will be readily understood.

when it is stated that in building the conservatory plate glass was employed in the roof wherever additional strength was required, whilst the side sashes consist exclusively of that costly material.

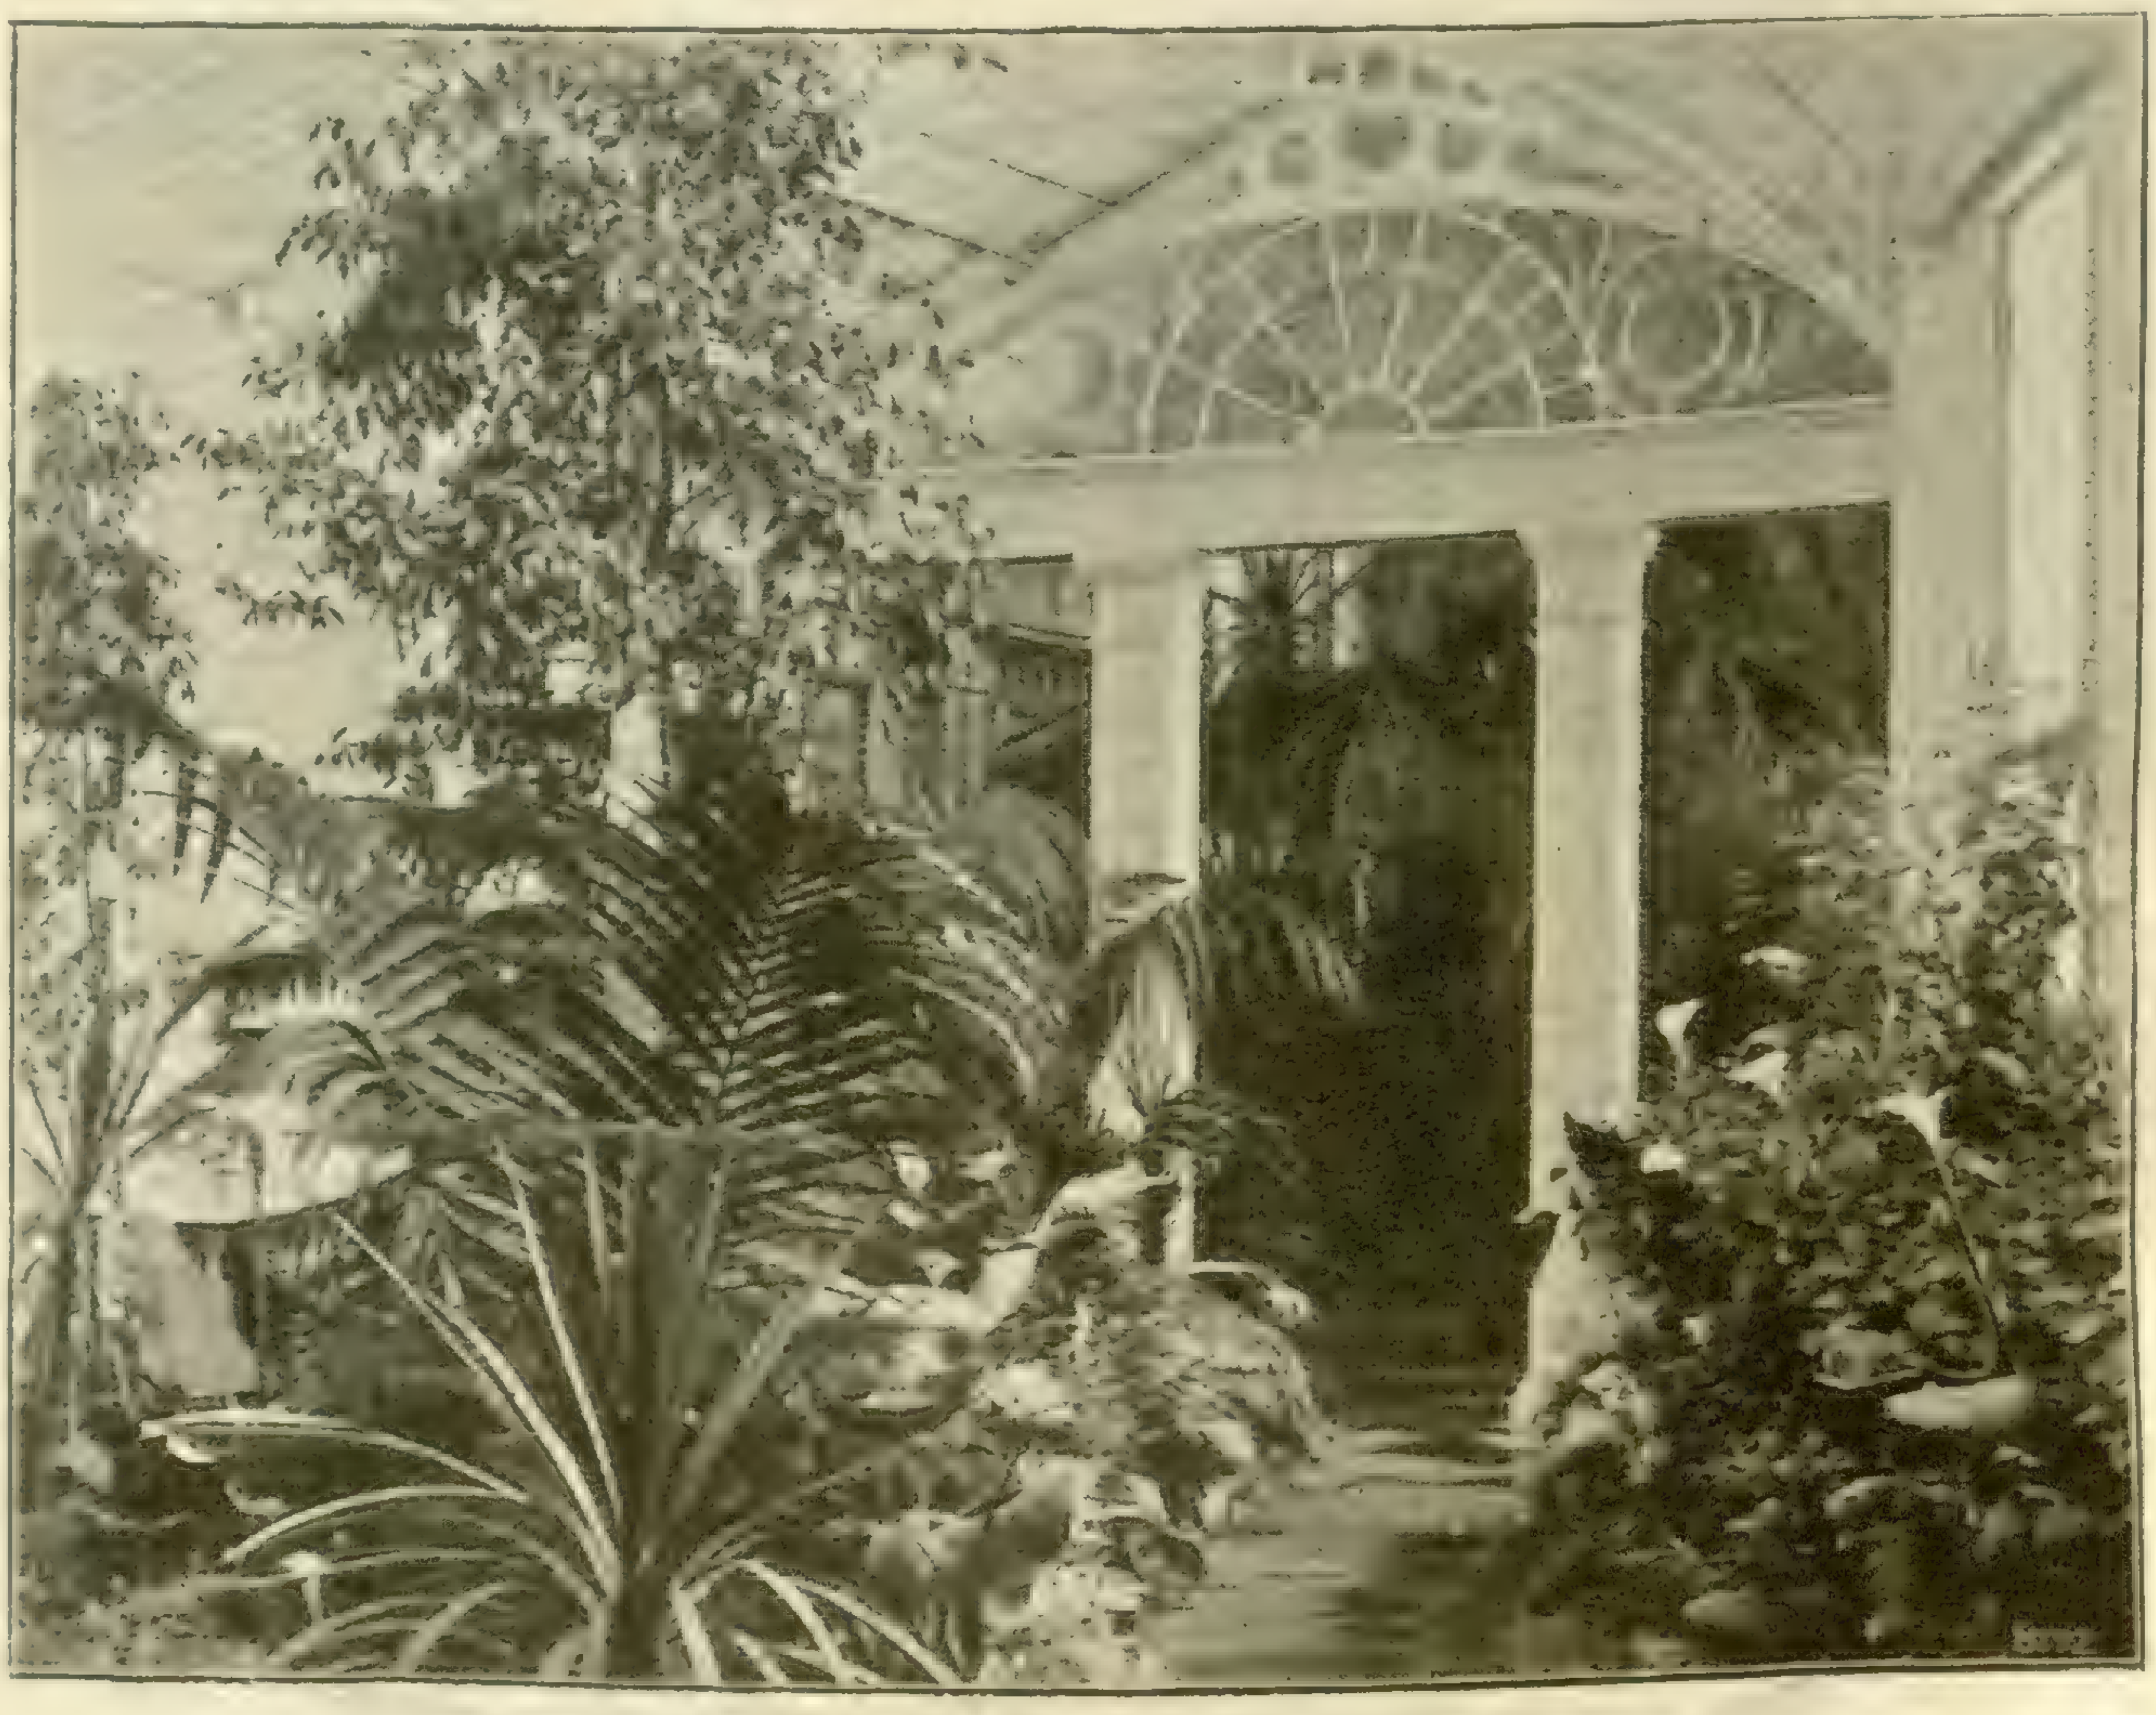
There has been no material alteration in the central portion of the building, nor would it have been practicable, if desirable, for the whole of the specimens are of exceptional size. Especially worthy of mention are the specimens of the Sugar Palm; Cereus hexagonus, one of the largest of the cacti, and here rising to a height of twenty feet or so; Bambusa arundinacea, unquestionably the finest specimen in the United Kingdom, the columnar stems about two feet in circumference, rising to a height of sixty feet, and filling the cupola with a cloud of elegant greenery; and Monstera deliciosa, which has attained a height of about thirty feet, and covers a large space with its huge singularly-divided leaves. This specimen is quite unique, as may be gathered from the illustration given herewith, but to have done it full justice a page illustration would have hardly sufficed. In the two wings at the extreme ends are glorious masses of camellias, planted out in a border against the wall, and finely-developed specimens in pots of Araucaria Bidwilli, A. Cooki, A. excelsa, and A. Rulei; palms of various kinds that thrive in the cool house, acacias, Dracæna australis, D. indivisa, tree ferns, notably cyatheas and dicksonias; Clethera arborea, which annually produces a wealth of its elegant pure white flowers; and the Loquat, which here fruits freely. In each of the corridors there are two oblong beds, with spaces for the grouping of plants in pots, and in the beds bold-growing plants, remarkable for the beauty of their flowers or foliage, or distinguished by elegance of aspect, have been planted out. With these will be associated flowering plants grown in pots according to the season. When the photograph of this portion of the building was taken, from which our illustration has been reproduced, richardias were used with singularly good effect. There is a narrow border both against the glass front and back wall, and in each of these climbers have been planted, as it is a part of the scheme of decoration arranged by Mr. Wythes to drape the wall and the spaces between the upright sashes and festoon the roof with plants of scandent habit. The corridors afford an exceptional opportunity for demonstrating the characteristics of the [illegible] of the greenhouse climbers, and a glance at the plants that are rapidly becoming established reveals the fact that Mr. Wythes fully appreciates his opportunities in this case, as in other details of garden management.



MONSTERA DELICIOSA AT SYON.

It remains to be said that the whole of the alterations have been so admirably conceived and carried out as to justify the bestowal of the highest praise on all concerned. The whole of the structural alterations, including the arrangement of the floor space, were made by Mr. James Gray, of Chelsea, and the rearrangement of the hot-water apparatus was effected by the Thames Bank Iron Company, and Mr. Wythes speaks in high terms of the manner in which the work in each case has been completed.

GEORGE GORDON.



WEST-END OF CORRIDOR, SYON CONSERVATORY.

THE BEST GUIDE to the garden for the whole year is the "Gardening Year Book," containing practical articles on the cultivation of Flowers, Fruit, Vegetables, &c. Price 1s. "Gardeners' Magazine" Office, 4, Ave Maria Lane, London.—[ADVT.]

VEGETABLES FOR EXHIBITION.

SALSIFY.

SALSIFY (*Tragophogon porrifolium*) is commonly known as the "Oyster Plant," and it is a much esteemed vegetable in many establishments when properly cooked and served. Good roots are easily obtainable when properly treated, as the crop deserves to be. A light, sandy loam, which must have been manured the previous year, is the best for producing fine specimens, and land from which the celery crop has been taken, if it can be so arranged, is preferable to any other. The ground should be deeply trenched during winter, and forked over about the middle of April. It is a common mistake to sow the seed too early, and thus a very large percentage flower prematurely, and the roots are worthless. The first week in May will be full early enough for sowing. Drills should be drawn about an inch and a half in depth, and eighteen inches asunder, and the plants eventually thinned to twelve inches apart. In very dry weather I have found the house sparrow troublesome in eating off the young tops, and have frequently found it necessary to protect the crop with garden netting. Every encouragement should be afforded the crop during the growing season by frequent hoeings, and in showery weather the application of small quantities of artificial manure. I have found soot strewn on during the evening act as a fine fertilizer. The crop may either be lifted in the autumn and stored in sand or ashes, or lifted as required. I prefer the latter plan, taking care to have sufficient uplifted in readiness for use in case a spell of severe weather occurs.

Salsify deserves very much more encouragement at our shows than it generally receives, and when classes are made for single dishes of vegetables at our autumn and winter exhibitions, I am most certainly in favour of this being included. The difference between poor and well grown specimens is most apparent, and in a large collection of vegetables, say, of twelve distinct varieties, during its proper season, I should not hesitate to include it if of first-rate quality. If salsify were in opposition to turnips, both being presented in good condition, I should most assuredly give the preference to salsify, if judging. Few things are more easily and quickly obtained than turnips, but this is not the case with salsify, which requires much more skill and forethought to bring it to perfection. When it is the intention of the cultivator to have it of the best quality for the exhibition table, it will be necessary, on most soils, to bore holes and prepare soils exactly in he same way as advised for carrots. A row or two done in this way will be sufficient, as one may be pretty certain of good results. The crop should be thoroughly mulched and watered in dry weather, of course allowing one plant only to each hole. When lifting, great care should be taken not to break or damage the roots, which should be clear, stout, and tapering, resembling a well grown beetroot, but not quite as large. They should be thoroughly washed and the small rootlets neatly removed. Nine or twelve will make a good dish, and they should be arranged in the same way as carrots or beetroot. In a miscellaneous or ornamental collection of vegetables, salsify should always find a place.

Aldenham House Gardens E. BECKETT.

THE FASCINATING FLORA OF YUNNAN.

THOSE who have closely followed the discovery and introduction of new plants during the past ten years wlll have, from time to time, admired the keenness of research exhibited by Dr. Augustine Henry, who expends practically all his leisure time in collecting plants. Dr. Henry is a member of the Customs Department, and his address is Mengtse, par Laokai, Tonking. Yunnan is the Chinese province wherein Dr. Henry has made wonderful discoveries of plants, both interesting botanically and useful horticulturally. His immense collections have not yet all been determined, but sufficient is known to show that Dr. Henry is not simply a collector, but a botanist of no mean order and a broad-minded naturalist. The richness of the Yunnan flora, with its Himalayan types shading into the purely Chinese, was not suspected until Dr. Henry made serious investigations. Some idea of his keen perseverance, the flora itself, and the difficulties under which he labours may be gathered, however, from the following extracts, which we take from a series of letters sent to Kew by him in 1897, and now published in the *Kew Bulletin.*

Writing at the end of February, 1897, Dr. Henry says: I have just returned from an exceedingly interesting trip to the country south of the Red River, in a district ruled over by an hereditary chief, who treated me with great kindness. I reached the great range separating the Red River and Black River basins, densely wooded with large trees (twenty feet in circumference) to near the summit, where they are replaced by thick bamboo jungle, so that the range, which is very long, is only crossable by passes at different points. The altitude is 8,000 to 10,000 feet. At this, the dead point of the year as regards vegetable life, there was not much out in flower, but I secured a magnificent rhodendron, a magnolia (both great trees), three camellias, Stuartia, &c. There was a Daphne (*indica?*), a shrub with deliciously scented white flowers, a primula at the summit, Ainslæa, two or three species of clematis, &c. Two or three Araliacæe, shrubs and trees, occur also up to the summit. A very common tree was Oliver's Tetracentron sinense, an enormous tree, but with the wood little esteemed. Its fruit spikes were scattered everywhere, and its minute seeds had flown away.

I spent two days on the Red River, where the vegetation is tropical; the banana, tomato, carica, and tamarind occurring everywhere in the wild state. The bizarreness of some of the fruits here was very striking. One tree (Dolichandrone cauda-felina) has long pods (two to three feet) with a dense covering of thick brown hair, exactly like the tail of an animal. On the plateau (7,000—6,000 feet) between here and the Red River I found a curious primula, with radical leaves besetting its base like an onion; it successfully resists the grass fires which here are universal, and flowers indifferently level with the ground or on a peduncle six to eight inches high. Immense evergreen oaks occurred in the mountain forest. The most interesting part of the trip was the aborigines. In the State, twenty miles by twenty miles, ruled over by the chief, not including Chinese settlers, I met with seven distinct races, *i.e.*, distinct physiognomy, speaking mutually unintelligible languages, living apart, never intermarrying, and with different customs and dress. Great red deer, bears large and small, occur in the mountain forests, the smaller bears leaving scratch marks on the trees, in which they build nests to sleep in. I have laid, I hope, the seeds of a friendship with the chief, and hope to gain much thereby, *i.e.*, an intimacy with the aborigines, which is a difficult matter indeed.

My own collection (April 30) has already attained gigantic proportions. I have numbered and labelled 660 distinct species, without making a perceptible gap in the immense pile of bundles of dried plants. I almost anticipate 3,000 species in this year's collection, *i.e.*, the year finishing on July 1. My muleteer is doing good work, being constantly on the road; and I myself am doing everything within a radius of fifteen miles round Mengtse, which includes mountains to 7,000 feet altitude. Pranchet, I believe, estimates Delavay's species from Western Yunnan to be 3,000 in number. Both our collections will have at least 5,000 species, and I venture to predict that Yunnan, when thoroughly explored (say in the twentieth century), will be found to have 10,000 species of plants (phanerogams and ferns with their allies). The rhododendrons have been very captivating. They vary in size from gigantic trees to the tiniest shrubs. The most striking one is apparently confined to a mountain peak north of here, some twenty miles. It has broadly oval leaves, about twelve inches long by eight inches broad, brown on the under surface, and the flowers are a delicate primrose-yellow, quite large and very numerous. The clematis are about twenty to twenty-five species; oaks fifteen; primulas ten (these have been very disappointing in number, and none is conspicuous in any way). The conifers include Cunninghamia, Cryptomeria, Keteleeria, and three species of Pinus; one of these is P. Massoniana; another is very remarkable for its perfectly white bark and large cones, with big edible seeds, perhaps allied to P. koraiensis and P. Armandi; the third I have just discovered. It is one solitary big tree planted on the top of a mountain, over four graves. I have not yet secured cones. It is beautifully pyramidal in shape, and with delicate, very green foliage, and different from any pine I have seen in China.

Talking of soap-trees, there are two here, Gleditschia Delavayi, with its enormous pods, some twenty inches long, and Pancoria Delavayi. The latter is an exact imitation of Sapindus Mukorossi. Of course, it differs technically in flowers and indumentum of the leaves, but no mere non-botanist would dream of putting them in different genera. I will send plenty of fruit of both (and seeds). The Leguminosæ are very numerous; Desmodium, Lespedeza, and Pueraria running riot in number of species. I have secured some very northern forms, as a fagus, a betula, &c. I am inclined to think that isolation, as in Yunnan by its multitudinous ranges and valleys, must play a great part in the invention of new species, and the study of the flora of this province will, I think, enable some one hereafter to get at important factors in this evolution. One of the most curious so-called species here is Ehretia corylifolia; it is a distinct species, but how near it is to the common Ehretia macrophylla! if I don't mistake, I think I shall get connecting links. *Pari passu* with the richness of types in the vegetable kingdom is the extraordinary diversity of the genus Homo. One is inclined at first to think that all the tribes one hears of must be the same people often under a new name. That is not so; the languages are distinct, and the physical characteristics are often very well marked, too.

In addition to my own collection, I have received from Morse, at Lungchow in Kwangsi province, some four hundred species. Some are quite interesting. He sends me Tournefortia sarmentosa, which is hitherto known only as an oceanic plant (Formosa, Mauritius, Philippines, Australia), and it is like the very pretty Osteomeles anthyllidifolia in this respect. By the way, have you the latter in cultivation? He also sends me Dolichandrone cauda-felina, which I found on the Red River. Its pods are the most comic of fruits; a long tail of some prehistoric animal would be near it. What is the meaning of the projecting hook on [illegible] of trees, such as Cæsalpinia sappan? Is it because other climbing [illegible] have such a point? It does not mean a time when tall beasts like giraffes and so on rambled about and got fruits from big trees stuck in their wool. Of course, there are monkeys running about in the trees. I cannot see any possible use, [illegible] in hairs of fruit of Pueraria Thunbergiana, at least any at present. The [illegible] stick on the climbing shrub till they dehisce, and out drops the seed. I forgot to say that I have secured a magnificent Paulownia (the flowers are [illegible] precocious). Unfortunately, I have not flowers of either of the two described Paulownias (P. Fortunei and P. imperialis) to compare with it, but it seems to differ from both; it has much smaller capsules than P. Fortunei, according to description. It is the most magnificent tree, in some ways, that I have ever seen. Seeds of it will have to be collected later on. It would really take a dozen enthusiastic botanists to cope with the work here. The lilies are only four so far: Lilium Browni (?), a lily with yellow flowers, numerous; and a small lily with a solitary pink flower, and L. giganteum. The orchids are very numerous. But I could go on indefinitely. My photographic camera, which has been four months on the way from Haifong to here, is just about to arrive. Can you give any suggestions concerning the uses of photography in botany? Of course, I suppose pictures of trees like the Paulownia, just spoken of, pictures of curious fruits, &c., will be useful.

After relating a little adventure with a leopard, Dr. Henry continues: With regard to seeds, I will do what I can, especially later on, when I shall have less plant-collecting to do in our immediate neighbourhood. But it is really a difficult matter collecting seeds; one arrives on the ground too late or too early. I tried, *e.g.*, to collect seeds of Gentiana serra and rhodantha, common plants, and failed to get a single seed. You may say, why not employ a native? Ah! you do not know the Yunnanese. My muleteer, who collects plants, is the only man I know who could or would do the work, and even he only does about one-tenth of what I could do if I had his time. The others, Chinese and aborigines, are too lazy for seed-collecting. I have secured the first aborigine who would venture into foreign employment; no one had any but Chinese before. He is my groom, and is an experiment. The fact is, that if one had nothing else to do, one might organise plans and people for carrying on such work; but it is difficult for me, as I have a great deal to do. And yet I doubt if many of my specimens will be collected again for fifty years, as I have put no small amount of energy into parts of the botanising. The flowers of a certain Zanthoxylum have cost me three visits to one spot and a expenditure of six hours' time. Money is not what is wanted, but time —oceans of time. Nothing astonishes people at home so much as the fact, a real fact, that in countries like China you cannot do everything with money. Patience is more valuable. I can get a good deal of work out of Chinese on a trip when I am with them, but not otherwise. Chinese are very susceptible to weather—a shower breaks their hearts; they don't like going into jungle, as thorns [illegible] them and tear their clothes. Now, I do not mind a hundred thorns; I wait till I have a lot in, then sit down and pick them out. For the Chinese, the root of the matter is an absence of nervous energy. Their industry, so much talked of, is unreal in most parts of the Empire. They are not exactly lazy, but they do not know how to begin to work, as compared with a European. And as to their ever seriously fighting or competing in the arts of peace or war with the Anglo Celtic race, it is an idle dream.

I would suggest, so great is the variety and beauty of the Chinese flora, and so fit are the plants for the European climate, that an effort ought to be made to send out a small expedition, the funds, *e.g.*, being provided by a syndicate of, say, a horticulturist, a private gentleman or two, &c. I estimate £1,000 would cover the expenses for two years; and what I would recommend is that a man be selected who has just finished his botanical studies at Cambridge. I mean, do not send a collector, but a gentleman, a student and an enthusiast. The locality I would suggest is the mountain range separating Szechwan from Shensi, or thereabouts, the expedition starting from Ichang in April and covering two seasons. A person like me, with daily official work, can do little or nothing. We live in towns, in the midst of cultivation, and the distances to get to the hunting grounds are enormous, and when we do get there we are half worn out. There [illegible] something uncanny in the way in which herbaceous plants disappear [illegible] after they have had their gaudy season of flowering, and when the plant [illegible] the seeds are green, or the capsules are empty. Such are some of the difficulties. My own plant-collecting, since I have been here, is enormous, but at such an expenditure of muscular force! It would be strictly paralleled by that of a bank clerk in London who made excursions on Sundays all over England, and two or three times a year made hurried trips to the Carpathians and the Pyrenees. The bank clerk would really in such a way expend less energy.

I have been reading your [Mr. T. W. Thiselton Dyer's] account of the [illegible] men, which I find very interesting. In a place like this, where one is overwhelmed with the multitudes of the species of plants, one is interested in any [illegible] concerning the reason why. In a previous letter I spoke of the red clay [illegible] so common in this province, and hinted at its possible glacial origin, but I [illegible] think now there has been the slightest glaciation here; the clay is simply a [illegible] out of the universal limestone, and what one finds here is a country which [illegible] not been disturbed geologically for an immense period. The country is [illegible] into innumerable valleys and petty plains and isolated peaks; and isolation [illegible] to be the factor which has kept up so many different forms of life, once [illegible] started. Another interesting series of questions is to find out what are [illegible] the supposed adaptations one sees, *e.g.*, what is the use of the fur like [illegible] on the fruit (an enormous fruit) of Dolichandrone cauda-felina, a [illegible] occurs in the Red River valley. In this hot steaming valley there are [illegible] ordinary fruits; nowadays there are scarcely any large animals, except [illegible] leopards. But there are multitudes of large and ferocious ants which [illegible] foliage of many trees for nest-building purposes. I assume that [illegible] this kind has a meaning, a use, if one could find it out, and people forget the [illegible] which enormous and curious animals in former geological times have [illegible] Take the question of thorns. I think they do serve as protection [illegible] and are not, as regards their preservation, when once developed, mere [illegible] of climate and soil changes.

I was quite disappointed in the spring flora here. The first half of the year [illegible] rainless, and, except in woods with perennial springs and streamlets, the [illegible] country remains almost barren. There is consequently a great variety of [illegible] which can bear long and sustained drought, and the dodges are innumerable. The bulbous covering of scaly leaves in the primrose I mentioned as coming up in [illegible] burnt grass hills is, of course, not a dodge against grass-fires, but a dodge [illegible] the drought it sustains. There is one point in connection with the [illegible] cultivated Primula sinensis which is not, I think, generally [illegible] form occurs in such a different condition of soil from what is adopted in cultivation. In the Yangtze gorges the wild form grows on cliffs in practically earthless ledges, and merely midst the piled-up remains of previous years' leaves, &c. In a word, it occurs in the driest possible situation, and I do not think even in wet weather, in summer, these ledges, when it occurs, really get wet. I am now speaking from memory, but I think I am quite correct as to the habit of the wild plant. The ledges, often hundreds of feet in length, present a beautiful appearance at flowering time in the dry winter season. In connection with this, there is no history to be got of when or how the Chinese began the cultivation of such plants, and it is quite remarkable how few specimens of really wild forms of many cultivated Chinese decorative plants there are, and also curious how many plants called japonica are only Japanese in cultivation, and are originally Chinese in origin. It is also remarkable that the Chinese shrubs in cultivation are scarcely the ones which make the best show in the wild state. At least, that is my opinion. In conclusion, I can see now that there were hundreds of interesting points which I might have noticed earlier in my plant-collecting if I had had the experience or the genius or the teaching. If you ever again come across a budding collector like what I was when we began correspondence some years ago, please insist on his being more than a mere collector, and perhaps you will help to develop a naturalist.

In an August despatch, Dr. Henry writes : I enclose a photograph of a palm taken by Mr. Bons d'Anty in the Upper Shan States south of Szemao. He is the French Consul at Szemao, and is collecting some plants for me, the interesting ones of which you will receive later. He says : " The palm is very common ; it is seen around every temple, and the leaves are used to make paper with, or rather are used as paper, being cut into long strips. In the photograph one can see the way the leaves are cut off for this purpose." I am in doubt as to what the palm is, but doubtless you will be able to identify it at Kew [probably Trachycarpus sp.]. The palms used as paper are Borassus and the Talipot palm, according to Treasury of Botany, but it does not seem to me to fit in with descriptions of these. I also enclose for the Museum, if you think it is of sufficient interest, a sample of the palm-strips with writing on it, sent me by Mr. Bons d'Anty. The writing is probably Shan, but Mr. Bons does not say. From a packet of plants sent me by Mr. Bons, collected on a trip south of the Chinese frontier, into the British Shan States, it would seem that the flora changes at once into the Indian type the moment the Yunnan plateau is left, *i.e.*, it loses Chinese looks. We are having a wet summer, much more wet than last year, and it is very unpleasant. The plague goes on apace. I tried to go out yesterday to the mountains, but had to return on account of the heavy rains. I stayed some little time at a Lolo village on the plain, and rested under a magnificent mulberry, the finest I have ever seen. It had the enormous spreading-on-the-surface-of-the-ground roots, which I think is called Table-kind of root. I went in quest of a Lolo Pundit that I heard of, but we found his house and the compound deserted, as there had been three cases of plague, and the Pundit had fled. I hope to secure his services, but the Lolos are very shy, or rather, I think, they are afraid to link themselves with Europeans, as the Chinese suspect them then of ulterior designs.

Apple Dumelow's Seedling.—I think there must be many who cannot be fully acquainted with the merits of Dumelow's Seedling, one of the most valuable apples for kitchen use in midwinter, or we should see it cultivated more, especially in private gardens. In my opinion it cannot be surpassed; it comes into use early in December, just as there is a demand for good solid fruit for mincemeat, and we need no other to furnish the supply till late in the spring. I know of no other cooking apple to equal it for retaining its firmness and solidity after storing, or for producing a white appearance after cooking. I admit it is rather acid, but that difficulty can easily be surmounted. Out of a selection of over one hundred varieties here this is the variety grown most, and though, generally speaking, apples were scarce with us last season, we were enabled to store from fifteen to twenty bushels of this variety, which have proved invaluable to us.—C. MARTIN, *Cowes.*

Links Between Animal and Plant Life.—In discussing the lowly organisms known collectively as Acinetaria, Professor Ray Lankester gave some interesting particulars relating to the organisms that form, as it were, the boundary between the animal and vegetable kingdom. In his description of the Acinetaria Professor Lankester said they had a simple nucleated-body with one or usually many processes extending from it. These processes were not purely protoplasmic but of definite structure, and were either pointed or ended in suckers which enabled the organism to suck juices from other creatures. Besides dividing by simple fission and conjugating, they also broke up into buds each having a bit of nucleus. These buds separated, and, remaining for a time in a cuplike hollow of the parent's body, acquired a girdle of cilia, which were regarded as evidence of the connection of Acinetaria with the Ciliata. It was probable that the first living things developed from albuminous matters were animals, subsisting on much the same substance as that of which they were composed. At some time in the growth of these living things chlorophyll came into existence, and enabled such as had it to assimilate carbon from carbonic acid and nitrogen from ammonia. The intermediate forms between these and the forms that required albumen were derived from green plants and fed on juices containing sugar and less highly elaborated substances than albumen. Fungi and lichens had this saprophytic mode of nutrition. The adaptability of plants was shown by those carnivorous kinds which digested animal food by means of a ferment. In such the roots became very small and assimilation by the leaves very slight. There was no group of simplest plants corresponding to the Protozoa, and there was no break in the plant series as in the animal. But if a division of plants were attempted, the simplest classes would be Confervoidea, Conjugata, and Schizophyta. The first were platelike or spherical forms, which separated into biflagellate individuals, forming zoospores that conjugated to produce a single mass, whence the new colony arose. If these were imagined to unite in a straight line, a confervoid form would be obtained. In the true filamentous confervæ each member of the series could break up into little bits which escaped just like the zoospores of the Flagellata. The Conjugata were filamentous or single cells, but never formed zoospores. In the Schizophyta, continued division of the cells was the only means of reproduction. There were two series. The Phycochromaceæ lived in fresh or sea water, and had peculiar colouring matters, often without chlorophyll. Their physiology was not well understood. The second series—Bacteriaceæ—were little removed from the first, though they were smaller and more dependent for food on organic matter. The simplest forms of bacteria were filaments which broke up into separate elements; and in a few cases the protoplasm collected and formed resting cysts, which would dry and float in the air, germinating when damped.

WORK FOR THE WEEK.

WARM ORCHIDS.

THE results of our labours will, to a large extent, be seen now in the fine display of flowers of different kinds which will be found in the orchid houses; in almost every collection Cattleya Mossiæ and its varieties, C. Mendeli in variety, C. Skinneri, and C. Schröderæ, will be flowering freely. The latter is one of the gems of the cattleya family, there being such variation of form and colour, in addition to the beautiful odour arising from it; every lover of cattleyas should grow plenty of this, as it is always welcome, and flowers after the earlier forms of C. Trianæ. When in flower C. Schröderæ ought to be kept in a dryer atmosphere than usual, it being very sensitive to damp; it can also be kept back to flower later if required by affording it a cool and dry house. Retarding, however, is not a wise practice, and it is much better for the welfare of the plant to treat it as naturally as we can, allowing it to flower in its proper course, and resting it in the same way. The repotting of the cattleyas mentioned may be done after the flowering season is over, the pots crocked as before advised, using a mixture of fibrous peat and sphagnum intermixed with a few fine crocks. After repotting little water is necessary if syringing is done over and between the pots twice a day; this will suffice until active growth takes place, then plenty of water must be afforded.

Lælia purpurata will also be giving a good display now, and few species are better worth growing, for it is both attractive and bold. L. purpurata Schröderæ is quite distinct, the labellum being beautifully veined; L. Russellianum is in the same style, but not so good; L. p. Backhousiana is another very distinct form, the petals being beautifully feathered and quite different from the ordinary type. Lælia Boothiana is an old orchid, and not much cultivated, owing to its shyness of flowering; yet this plant thrives well if grown with L. purpurata, and the roots allowed to run over the rim of the pot; in fact, we scarcely see it in flower when kept within bounds—it loves to be free, and enjoys moisture. Lælia Latona, a hybrid resulting from L. purpurata crossed with L. cinnabarina, is a grand addition to our hybrids; this may be grown successfully among the cattleyas and lælias. Some vanda of the V. tricolor and V. suavis section will be in flower, and care must be taken to keep the flowers dry; neat stakes will also be necessary to support their weight. Vanda teres will also be flowering, and great care must be taken of the flowers, for bruises soon appear if they are handled roughly. Sobralia macrantha, and S. m. alba—the latter, with the exception of the lemon at the top of the throat, being as pure a white as can possibly be seen—are now flowering. The type is not much sought after, the flowers lasting such a short time; an occasional dose of weak liquid manure will be beneficial to sobralias. Thunias, being of quick growth, will already be showing flower buds; the syringe must be used freely to prevent red spider and thrips, as these orchids are very subject to both pests. Peristeria elata, perhaps, will be found in the collections of amateurs, and if repotting is necessary, this may be done now; if not, do not pot for the sake of doing so. Fires must now be checked early in the morning, and plenty of air be afforded in a proper manner; watering and syringing must be done with discretion yet.—T. STAFFORD, *Tyntesfield Gardens.*

CONSERVATORY AND GREENHOUSE

FOR the most part chrysanthemums will now be occupying six-inch pots, and as it is not usual to give the plants the final shift until the end of the months they should be attended to at least twice a day during bright weather to see that they do not suffer from want of water. It is also necessary to allow the plants plenty of room in order that they may retain the lower leaves and make sturdy growth. Where a large quantity is grown suitable pits and frames are not always at command to afford the protection the plants still require at night, therefore temporary ones have to be provided until it is safe to fully expose them. A sheltered nook should be selected, and the plants arranged on a bed of ashes, round which place sheephurdles, or boards, to break the wind and to support the night covering.

The plants should be twisted round at least once a week to prevent them rooting into the ashes, and see that greenfly does not gain a foothold, to dislodge which we find it best to dip the tops of the plants in a weak solution of soft soap and water, or a little tobacco powder may be dusted where they are located. Some varieties have a tendency to produce flower buds, which must be pinched out as soon as they can be seen, and the plants encouraged to make clean growth. In the meantime a good heap of compost should be prepared in readiness for placing the plants in their flowering pots. By mixing this now, and turning it over once or twice a week in an open shed it will be in a grand condition when required, as the soot and horse-droppings would heat somewhat, and free the turf of wireworm and other insects.

We are now potting on our main batch of cyclamen raised from seed sown last August. The compost used consists of good fibrous loam two parts, one part of leaf-mould, one-seventh of decayed manure, and a liberal quantity of coarse sand. The plants are being placed in five-inch pots, and by growing them on briskly many of them will be strong enough for pots two inches larger later on. After potting afford a light shade, maintain a humid atmosphere, and avoid sudden inrushes of cold air. Give liberal supplies of water as soon as it is seen they are growing freely. If once allowed to become thoroughly dry weeks elapse before they are induced to grow freely again. All plants that have passed out of flower should be hardened off in a cold frame. Salvias in variety are useful winter-flowering plants, and where a batch have been rooted pot them on as they require it, pinching the shoots from time to time to make them bushy. They should now be placed in cold frames, giving full axposure whenever the weather permits, and so be sufficiently hardy for plunging in the open the first week in June. Many of the most forward plants of kalosanthes will be showing their flower trusses, and as the plants generally are grown in small pots, it will be almost impossible to overwater them, while weak liquid manure occasionally will greatly assist in securing fine trusses of bloom, and give the foliage a deep green colour. Weak soot water is also recommended for the same purpose. Place those intended for succession in cold frames to gradually harden them, where they may be stood in the open later on. Those intended for flowering next year must not be pinched back in any way, as the shoots require a full year's growth before they produce bloom. Pot them on, or if large specimens are required any number of even size plants may be grouped in large pots or pans, and they make bold objects in the conservatory when in flower. Bouvardias that have been kept in cold frames at rest are now starting naturally, and the shoots are very short-jointed and hardy, very different to those produced when the plants are started in a forcing-pit. We are now partially shaking them out, and replacing them in smaller pots. They will be kept close and shaded for a few days, afterwards giving them full exposure, and many of them will be planted out on a south border. In colder localities, however, it would be safer to grow them in cold frames, either in pots or planted out, so as to give the plants the protection of the lights, should the weather prove unfavourable to free growth at any time.—R. Parker, *Goodwood.*

THE FLOWER GARDEN.

The next few weeks will, in the majority of gardens, be an unusually busy time in this department. Where the stocks of such plants as ageratums, coleus, alternantheras, and iresine are still deficient cuttings may yet be struck in time to make plants for June. The easiest and quickest method is by a frame or frames on a hotbed of leaves or manure on which two or three inches of light soil is placed, a little sand sprinkled over the surface, and the whole pressed firm; into this the cuttings may be thickly dibbled just as cut from the stock plants, as at this season they strike most readily. Alternantheras form roots in a few days if kept close, and great quantities may be struck in a few weeks in this way by a continual topping. Hardening off should receive due attention, and any plants coming from a warm house into frames should be kept rather close for a few days; with bedding pelargoniums full exposure, after gradually hardening off, should be given for a week or two before planting out, otherwise the foliage will be liable to suffer from bright sun or cold winds. Where the beds in the flower garden are filled with spring-flowering subjects bedding out for the summer will be somewhat late unless the spring occupants are cleared out before really past their best, the cold and somewhat sunless weather of the last two months having considerably retarded their blooming. If the beds are empty, many subjects may be planted forthwith, especially the hardy groundwork of carpet-bedding arrangements, where these are still carried out. A more pleasing style of bedding is now, however, more generally practised, and plants of a less formal nature used. Edgings of hardy sedums may be made up, and the variegated grass, Dactylis glomerata variegata, quite hardy, makes a capital edging plant. Old clumps, if lifted and pulled up into small pieces, make good planting material, and form an effective edging to beds filled with crimson, scarlet, or pink pelargoniums; and is also useful for covering the surface of a bed as a groundwork where taller subjects are used. Fuchsias, heliotropes, pelargoniums, palms, &c., of four to five feet or more in height, may be used thinly dotted over large beds, with a carpeting of some low-growing or creeping plant, as sedums, mesembryanthemums, and violas, with others of intermediate height, from one and a half to two feet, of tuberous begonias, pelargoniums, or other subjects that may be to hand. This style of bedding is more generally attractive and now much in vogue.

Violas being quite hardy, should be planted out early, and given a chance of becoming well established before hot weather sets in. These also form a good groundwork in mixed bedding, where tall plants are used as mentioned above, while the blue and purple varieties may be associated with variegated leaved pelargoniums only, and make pretty beds. The old Manglesi variegated pelargonium, and the dark blue viola Archie Grant, the former being allowed to retain its small pinkish blooms, makes a charming combination of a simple nature. Stocks and asters should be planted out from where raised in frames, before becoming drawn: I sow rather late and transfer direct from the frame to the borders or beds where they are to flower. Zinnias, marigolds, scabious, gaillardias, salpiglossis, and others are treated in a similar manner, and invariably grow away quickly and do well. Roses are making slow growth, and already maggot and green fly are in evidence. The former must be destroyed by hand picking, or squeezing the rolled-up leaf with maggot. Green fly may be easily kept in check by syringing with a solution of Bentley's quassia extract, a most useful insecticide that may be quickly prepared for use by simply mixing with clear water to the strength advised in the directions. Delphiniums and other plants now growing fast in herbaceous borders should be staked and tied before they become long enough to fall over and grow into a twisted shape, as, when this occurs, they cannot be easily tied erect again. One of the prettiest subjects now in bloom in these borders is Tiarella cordifolia; others, including German iris and pæonies in variety, are fast opening, and the borders will soon assume a gay appearance.—C. Herrin, *Dropmore Gardens.*

HARDY FRUITS.

The cultivator will have plenty to do among hardy fruit trees for the next few weeks, as, owing to the genial rain we have had since my last notes, new growths have made good progress. The earliest strawberries on a south border are blooming freely, and with nice weather fruits will be very early in the south. So far, our earliest variety is Laxton's No. 1, and this is very strong also, but Royal Sovereign promises grandly; in fact, our young plants have been such a mass of flower spikes that it will be necessary to thin out for very early supplies. Mulching, as previously advised, should not be long delayed, and if not done before the flowers expand, it is best left till they are set; there is a great gain, however, in early mulching. Raspberries are now showing great quantities of suckers, and these must be reduced; the plantations must be mulched at this season, and some rich food may be given; in our light soil we give cow manure that has been prepared by placing it in bulk for a while. Old raspberry quarters will need food, and given now it conserves the moisture and builds up strong canes. Newly planted raspberry canes should not be allowed to fruit the first season; indeed, the canes should be cut down almost close to the soil, and if this is done strong shoots will follow. After a dry period, followed by warm rains, weed growth will be difficult to keep under in fruit quarters, so that the hoe should be kept going vigorously upon all favourable occasions. I do not know how the severe weather may have affected the crop of some fruits in the north, but with us gooseberries are scarce, and it will behove the cultivator to pay attention to those left. I find wood pigeons take the fruit when about the size of horse beans; indeed, the gooseberry appears to have many enemies; early in the year the small birds prey upon the buds, and we may now look forward to the attacks of caterpillars. The latter it is well to guard against at this season; we use lime mixed with dry wood ashes as a surface dressing, and find it answers thoroughly, indeed, it is much better given now than when the pest appears on the foliage. Of late years more gooseberries have been grown in an upright position, either trained against walls or a wire support. Last year I saw some trees in a quarter growing against wire fencing, in rows six feet apart, the wires being strained to posts about six feet high; this allowed of covering the whole quarter with a net, gathering the fruit with ease, and keeping birds at bay; at the same time the fruits were better than usual, the bushes having been given high cultivation.

With May well advanced there need be no delay in training peach and nectarine shoots, and in our case, with a sparse crop of fruit on the earliest kinds, the shoots are gross and will need early attention. Much may be done to keep strong shoots for extension, as the growth in one season, if allowed free play, will be great, and one may often do away with any misplaced old or weak wood now to give principal shoots more freedom. This refers to strong shoots on the main branches, and I would advise more freedom of growth, for we suffer much less from canker if young trees are not pruned too hard but allowed to cover a good space yearly. Far better remove intermediate trees than cripple young ones. Shoots springing from the base—those for next season's fruit supply—are often inclined to grow out from the wall, and these give trouble, as it is necessary to keep them in position; but they will now be in condition to be tacked or tied to the supports, and these may often be tied to the old bare wood as growth proceeds. Stopping shoots near fruits will need attention, as, though these may have been stopped previously, shoots push forth new growths, and again need similar treatment. It is well to note at this season that branches of young trees are not cut by ties given at their earlier training, as the shoots are now swelling freely, and the bark, once injured, cannot be remedied, while canker or gumming attacks the wounded portion as the trees attain age. It will not be advisable to defer thinning the fruits much longer; indeed, I have already removed a goodly number where at all thick. Early thinning is not often advised, as there is a danger of dropping during the stoning period. This may be in wet or heavy soils, but our trees never suffer in this respect; indeed, I find we do not thin enough with some varieties, as young trees bear so freely that they may be overcropped. In thinning it is well to examine the trees several times, and it will soon be seen what the trees can carry; in no case should a lot of fruit be left on one part of the tree and only a little on others, but every attempt should be made to distribute it evenly over the trees. The pear crop promises well, and the cultivator will soon be able to clear off the old flowers, which at times stick to the fruit and prevent swelling; with cordon and wall trees stopping will be needed frequently, and removal of useless spray will facilitate fruit swelling. Newly-planted trees will now need a mulch of good manure should they show any sign of flagging in hot weather, while a dewing overhead after hot sunshine will help to foster new growth. Trees recently grafted should be examined, and any that have failed to form a union should be allowed to make a new growth, as budding may be done later on. With grafts growing freely the binding may soon be loosened or moistened if necessary.—G. Wythes, *Syon Gardens.*

AN EXPERIMENT TO INDUCE SPORTING.

The references made some time since in the Gardeners' Magazine to the subject of sporting in chrysanthemums have suggested to me that the following account of an experiment I made in the season of 1896 may be interesting, even if it does not throw any additional light on the subject. It was in the dark days of the winter previous, while lamenting the hard fate of sundry flower-heads of chrysanthemums, which, after being carefully fertilised, had given up the struggle to produce ripe seeds, and hung down helplessly, a victim to "damp," the wish being father to the thought to produce new kinds suggested an experiment in grafting to gain the desired end. The idea may not be new, but as I have never heard or read of anything similar, perhaps it may possess a little merit of originality. My desire at first was to induce an artificial sport from the plant, but neither my reading nor my experience gave me a clue as to the best course of procedure. I had, so to speak, the material, but no tools or formula. Then the thought presented itself of graft hybridising, and though this is no new scheme, the method, so far as I know, is new.

Two plants of similar size but of very opposite character were chosen. These were in three-inch pots at the time, and were potted in pairs in six-and-a-half inch pots. After the roots had taken to the new soil the top of one plant was taken off about five inches from the tip, and a slit was made with an upward cut in the other at the same height. The point of the first was shaped into a long wedge, and inserted carefully in the slit of the second. They were then carefully bound with fine shreds of raffia, and some moss fastened round to insure moisture. Placed in a cool, shaded place, they united perfectly in about a fortnight. The plants were now growing two roots to one plant, and each was contributing an equal share to the maintenance of the growing foliage and resultant blooms. This was evident from stems of each stock swelling throughout the growing season. They were finally shifted into ten-inch pots and were placed with the rest of the collection. The varieties chosen were selected with an idea of ascertaining what effect the union would have on the colour and shape of the blooms. For this purpose Mdlle Thérèse Rey was united with Charles Shrimpton, the lead being taken by the first-named, so that any tinge of colour would show most distinctly on the white flowers. In No. 2, Mdlle. Thérèse Rey was again used in conjunction with J. S. Dibbens, the former being again the leader. In No. 3, Etoile de Lyon was coupled with Brookleigh Gem; in this case the incurved was given precedence, to see if the coarse reflexed blooms would influence its co-partner. In No. 4, Louis Boehmer and Mrs. F. A. Spaulding were wedded, the latter taking the lead; this was to try if the hirsute petals would tell on the smooth ones. No. 5 was Gloire du Rocher with Jeanne d'Or; and No. 6, Charles Shrimpton with Madame Charles Molin, the last-named in each case leading.

The results certainly were not very encouraging; in only one case could I see any variation from the normal. This was in No. 1, in which some petals were a decided pink. In all the other cases I could not distinguish anything from those under common conditions, the blooms, however, being exceedingly large and fine for their particular kinds. This hint may prove serviceable to big bloom growers, and prove a useful help to some beautiful but delicate kinds which have feeble root action; and perhaps might correct the deplorable bud-producing habit of others. As no patent rights have been secured for the process, I make chrysanthemists a present of the idea. Cuttings were taken above the union from the plant which showed a slight pink tint and grown on last season, but they showed no variation from the true variety, and so I suppose the experiment ends, and I am as far as ever from producing sports by artificial means.

To my mind, however, it seems to prove that the roots have little or nothing to do with the colouring of the flower, for although two root stocks were assimilating material and mingling the resultant sap all the summer, yet nothing of a colouring nature could have been collected by them. This, of course, may be nothing new to those versed in colour science and plant structure, but perhaps the experiment may have other teachings to them, and this must be my excuse in taking up so much space to record it.

Wollaton, Notts. R. E. Richardson.

EXHIBITIONS AND MEETINGS.

ALEXANDRA PALACE SUMMER SHOW.

THERE can be no doubt as to the suitability of the central hall at the Alexandra Palace for a big flower show. It is a splendid place with abundance of room, and plenty of light without brilliant sunshine. The exhibition under notice was to a large extent lost in this building, but that was largely due to the near approach of the Temple Show and the Manchester Exhibition, for many would-be exhibitors were holding themselves back for these. If substantial prizes are offered at some future and more suitable date the result should be a really fine exhibition. There would be fine opportunities here for the display of big specimen plants, such as tall palms, tree ferns, bamboos, &c., indeed, for big plants of all kinds, as there would be no necessity for crowding. In addition to the central hall there are huge annexes to it, and these, if occasion demanded, could be utilised for flower show purposes. Certainly no place in London is so well suited for horticultural displays, such as rose shows, &c., and it is comparatively easy of access. The catering, such a consideration to exhibitors and visitors, is excellently done by Messrs. Letheby and Cristopher, of East Grinstead, and perhaps nothing could speak better for their conduct and provisions than the eulogies of the exhibitors and their attendants, who were provided with breakfast by the authorities. "Fancy having hot rolls for breakfast at a show," was the exclamation of more than one attendant.

PLANTS.

Mr. George Cragg, gardener to W. C. Walker, Esq., Percy Lodge, Winchmore Hill, gained a first prize for a table of orchids with a pretty exhibit, the orchids being arranged amid light palms, and over a groundwork of maidenhair fern. Good forms of Odontoglossum crispum, Lælia purpurata, L. tenebrosa, Cattleya Schröderæ, C. Bowringiana, C. citrina, &c., and over all a number of graceful branching spikes of the brilliant Oncidium Marshallianum. But one exhibit of nine specimen plants was staged, and this set came from Messrs. J. Peed and Sons, Roupell Park Nurseries, Norwood. The specimens were well furnished, and moderately large examples of Croton Weismanni, Dracæna Gladstonei, Phormium tenax variegatum, Kentia Forsteriana, K. Belmoreana, Dracæna Lindeni, Pandanus Veitchi, Latania borbonica, and Caladium Mrs. H. Veitch, the latter beautifully coloured. Messrs. J. Peed and Son, Norwood, won the first prize for a group of flowering and foliage plants arranged on a space of two hundred and fifty square feet. The group was circular, and consisted of a band of dracænas and caladiums surrounding a big central kentia and liliums. Nearer the front were bright crotons, heaths, boronias, begonias, gloxinias, hydrangeas, &c., all arranged amid maidenhair ferns. The centre of the group was somewhat too crowded, but on the whole the display was effective.

CUT FLOWERS.

In the class for a collection of cut flowers, arranged on a table fifteen feet by four feet, the first prize was won by Mr. Amos Perry, Winchmore Hill, who staged fine bunches of tulips, iris in abundance, including a yellow form of I. pumila named Leander, a rich yellow variety; violets, Geum Hildriechi, G. Eweni (orange), Gladioli, trollius, the pretty Anemone bacailense, phloxes in variety, Cheiranthus Marshalli, &c. Spanish iris in variety also added much to the attractivenes of the exhibit. For a large group of cut flowers, twenty feet by six feet, Messrs. Paul and Son, Cheshunt, secured the first prize for a showy collection, consisting chiefly of bunches of brilliant rhododendrons, Mollis azaleas, Parrot tulips, late narcissi, fragrant violas, some early pæonies, geums, Megasea cordifolia in fine condition, and several forms of the bluebell showing varying and pleasing shades of colour; Scilla carnea was very attractive.

For one bride's and two bridesmaids' bouquets Messrs. Perkins and Sons won the first prize, sending three exquisite bouquets all the way from Coventry; lily of the valley, eucharis, pancratiums, gardenias, Odontoglossum crispum, and O. Pescatorei were the flowers chiefly used, while maidenhair fern and asparagus fronds supplied the foliage. Mr. Henry O. Garford, Stoke Newington, came second, the bride's bouquet being artistically composed of gardenias, roses, and an abundance of stephanotis; the bridesmaids' bouquets were of yellow roses, yellow marguerites, and golden Spanish iris. Mr. L. H. Calcutt, The Bank Nursery, Stoke Newington, came third, his bridesmaids' bouquets of crimson carnation and lily of the valley being very effective. Some beautiful roses were staged by Mr. G. Mount, Canterbury, and, though there were no competititors, other exhibitors would have found the Canterbury grower hard to beat. Mr. Mount was first for twelve and for twenty-four blooms, his stand of twelve containing excellent examples of Ulrich Brunner, Mrs. W. J. Grant, General Jacquiminot, Catherine Mermet, Capt. Hayward, Fisher Holmes, Mrs. John Laing, Niphetos, and Caroline Testout. The set of two dozen contained superb blooms of Mrs. J. Laing, Capt. Hayward, Perle des Jardins, and Catherine Mermet.

The only display of twenty-four bunches of cut flowers came from Mr. G. Cragg, gardener to W. C. Walker, Esq., who put up Lælia purpurata, L. grandis tenebrosa, Cattleya Lindeni, Odontoglossum Pescatorei, O. crispum, O. Cervantesi, Epidendrum rhizophorum, Dendrobium thyrsiflorum, Cymbidium Lowianum, Anthurium Scherzerianum, Cypripedium calceolus, Canna Florence Vaughan, Cytisus albus, Tulip Golden Eagle, &c., &c.

NON-COMPETITIVE.

Mr. S. Mortimer, Rowledge, Farnham, showed a splendid lot of tomatos and cucumbers. The former were Conqueror, and an improved form, and Abundance; the cucumbers were chiefly Lockie's Perfection, Improved Telegraph, and Sutton's Peerless, all well-developed, clean specimens of good serviceable size. A gold medal was awarded to Mr. T. S. Ware for a very long table of hardy plants and flowers, early irises, Cytisus andreanus, narcissi, tulips. Geum Hildriechi, primulas in variety, dodecantheons, aquilegias, hardy orchids, Ramondia pyrenaica, Trillium grandiflorum, and a flowering plant of Richardia Rehmanni, the blush tinted calla.

Mr. James Williams, Oxford Road, Ealing, gained a silver medal for a light table decoration of narcissi. A small gold medal was awarded to Mr. L. H. Calcut for his pleasing exhibit of vases, epergnes, arches, and other elegant floral arrangements, the designs being executed in white lilies, gay Spanish irises, blue cornflowers, and brilliant anthuriums. Messrs. W. Edwards and Son, Notts, arranged ferns in artistic baskets. Messrs. Wood and Son, Wood Green, had a large display of horticultural sundries, including bamboo rods in all lengths and thicknesses, baskets, garden cutlery, samples of soils and manures. Mr. W. Colchester, Ipswich, staged a collection of samples of manures, including their speciality. A bold display by Messrs. W. Cutbush and Sons, Highgate, secured a gold medal; this consisted of big palms, bamboos, and baskets of hydrangeas, with Souvenir de la Malmaisons, carnations, heaths, mollis azaleas, heaths, Otaheite oranges, boronias, crotons, &c., in front, with an edging of maidenhair fern and isolepis; a good display. An exhibit of cacti from Mr. H. G. Bourne, Grove Villa, New Southgate, secured a silver-gilt medal; about a hundred and thirty plants were staged, including many rare species and some new phyllocactus hybrids. A small Cereus giganteus, over sixty years old, occupied a prominent position, as did C. cærulescens; several echinopsis were flowering and making new growths. Others were Mamillaria sub-polyhedra, Opuntia microdasys, Astrophytum myriostigma, stapelias, and Cereus flagelliformis, an interesting display.

READING GARDENERS' ASSOCIATION.

THE first meeting of the summer season of the Reading and District Gardeners' Mutual Improvement Association was held on Monday evening last, when the chairman of the Association, Mr. Turton, presided over a good attendance of members. The subject for discussion was hardy flowers, including shrubs and bulbs. This was introduced by Mr. Townsend, gardener to Sir William Farrer, Sandhurst Lodge, who said that he should refer principally to those varieties which made the garden look gay during the early months of the year, and only those which were grown in the gardens under his charge. The following varieties were touched upon. Flowering shrubs—Amygdalis, abelia, andromedas, buddleas, berberis, cydonias, cerasus, cratægus, ceanothus, choisya, cytisus, carpenteria, chimonanthus, calycanthus, cistus, cornus, deutzia, daphne, Diplopappus chrysophyllus, escallonias, forsythias, Garrya elliptica, genista, iberis, jasmine, kerrias, laburnum, Leycesteria formosa, ledum, mespilus, magnolias, nuttallia, pyrus, prunus, philadelphus, ribes, spiræa, sambusa, ulex, viburnum veronica, weigela. Bulbs—Hyacinths, tulips, narcissi, crocuses, aconite, chiondoxas, triteleias, scillas, grape hyacinths, alliums, ornithogalum, leucojum, dog's-tooth-violets, trilliums. Flowers (flowering from February till the early part of May) hellebores, violets, arabis, laubrietias, daisies, wallflowers, myosotis, primroses, polyanthus, alyssum, doronicum, alpine phlox, and Primula Sieboldi. A discussion followed. An interesting feature of the meeting was the large display of cut flowers, including Primula Sieboldi, daisies, myosotis, tulips, trilliums, pansies, lily of valley, wallflowers, narcissi, auriculas, honeysuckles, roses (outdoor growth), &c. These were contributed by Mr. Turton, Maiden Erlegh Gardens, Mr. W. Smith, gardener to Miss Neild, Greenbank, and Mr. Townsend, the latter exhibiting a splendid grown anthurium showing 45 spathes. A vote of thanks to the lecturer and to those members who had brought the flowers ended a pleasant evening.

ISLE OF WIGHT HORTICULTURAL ASSOCIATION.

THE monthly meeting of the Isle of Wight Horticultural Improvement Association was held at Newport on Saturday last, when there was a large attendance of members present, presided over by Dr. J. Groves, B.A. Mr. A. Key, M.A., formerly of Wadham College, Oxford, gave a most interesting and instructive experimental lecture on "Plant Foods: Their Detection in Vegetables and Soils." The lecturer stated at the outset there were seventy-two elements, and that fourteen of these were generally found in plants, several of them being indispensable and required in larger quantities than others; amongst these were "phosphates," for without which no seed would germinate and fruits would be practically worthless. Mr. Key then performed several experiments showing how to ascertain the presence of phosphates in soils, manures, fruits, and seeds. At the close he received a most unanimous vote of thanks. Several interesting exhibits were staged. Mr. G. Nobbs, F.R.H.S., gardener to Her Majesty at Osborne, received the association certificate for cultural merit for a fine spike of Imantophyllum (Lord Wolverton) with twenty-three blooms. Mr. J. J. Livington, gardener to Dr. Coombes, Newport, staged a fine plant of Dendrobium densiflorum, and Mr. J. Nicholas, gardener to Mrs. Gray, Kintore, Sandown, a well-flowered plant of Hydrangea. Eleven new members were elected. The first excursion of the season took place on May 19 to Appley Towers and St. John's Vicarage, Ryde.

EAST COWES HORTICULTURAL SOCIETY.

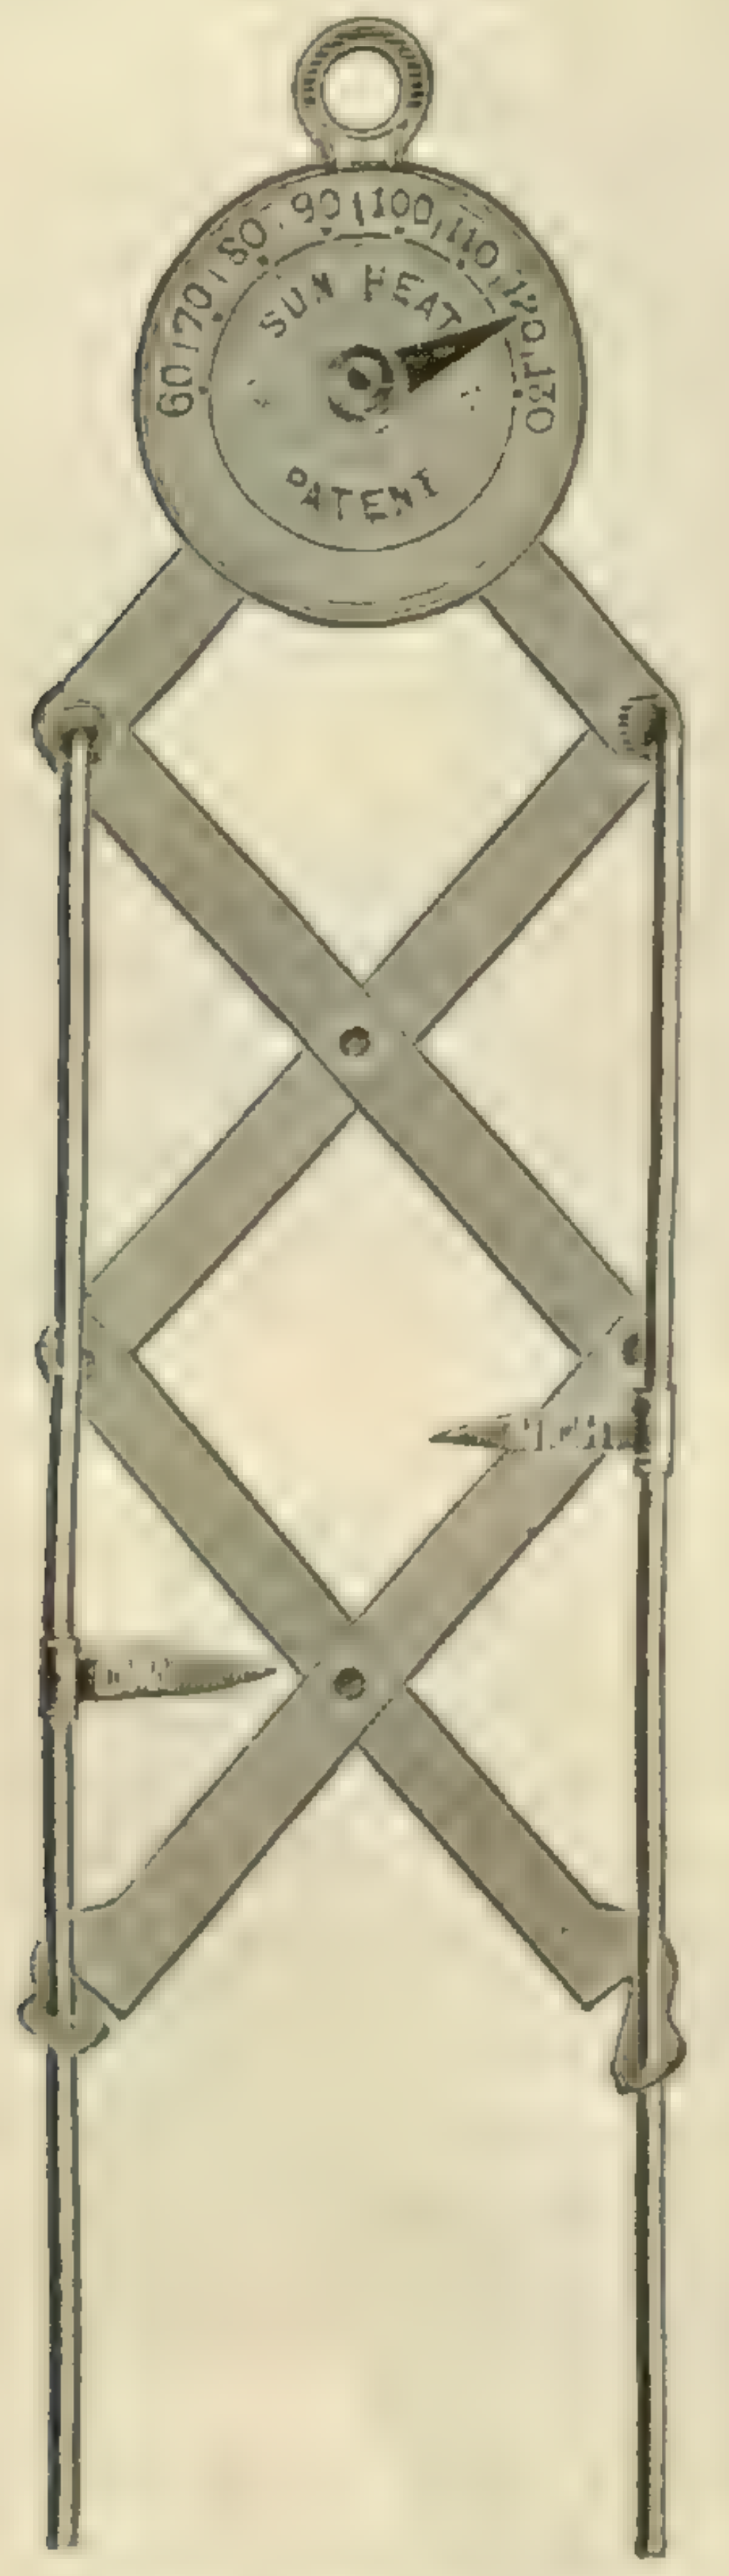
THE fortnightly meeting of the East Cowes Horticultural Society was held on Wednesday, when an excellent paper on the "Cultivation of Carnations" was read by Mr. A. Saunders, gardener at Stanhope Lodge, Cowes. The subsequent discussion proved very interesting and instructive.

The Pleasing Primrose.—I like that name best for the beautiful Primula cortusoides amœna (P. Sieboldi) in its many rich and charming varieties. Though fairly hardy, as it blooms through April and May, it thrives best in sheltered and and well-drained positions. The stature of the flower stems, the thinness of the flower and foliage, renders such favourable environments needful for the full display and careful preservation of their beauty. Those who cannot command cosy sheltered positions for their finer strains of the pleasing primroses in the open air, cannot do better than grow them in pots in cold pits and frames, or use them as window plants, or in cool greenhouses. These are very distinct and different from all other members of the primrose family, and the finer varieties never fail to please, either as plants or cut flowers in small and graceful vases, verdurised with their own elegant foliage.—D. T. F.

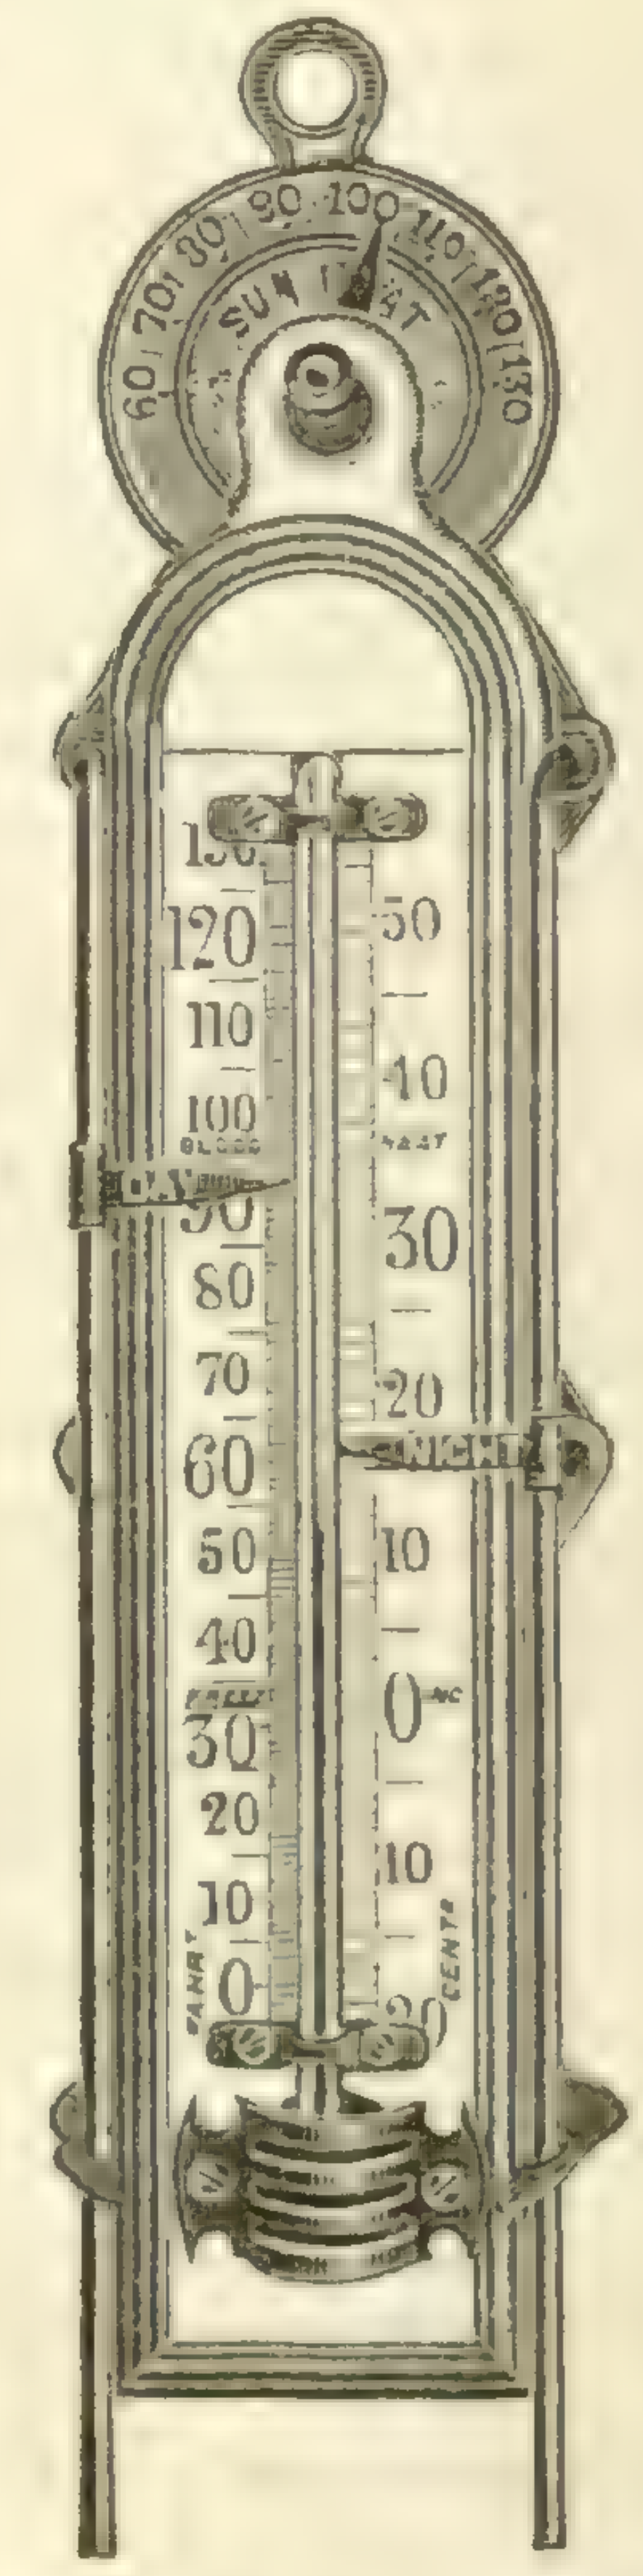
Border Auriculas.—What charm there may be found in these hardy plants even in a large town is evidenced by the exceedingly pretty display made by my fellow townsman, Mr Shepherd, of the firm of Puttock and Shepherd, whose private residence close to the town allotments is fronted by a garden of border auriculas. I saw the plants there the other morning when passing, and many were then in bloom, but by the end of the month the display will be a very charming one. This is not the only town example of the way in which the auricula does here, for there are other ones, but Mr. Shepherd has sought to improve his stock by selecting plants carrying fairly stout erect stems, and flowers of bright, effective colours. There is very much room to improve these auriculas in these respects, and those florists who love them but have no greenhouses or frames may find as much pleasure in cultivating these hardy varieties as the fancier does with his choice house-grown ones. In some respects perhaps more pleasure may be obtained, as these border forms admit of much advance and development. The choice show and alpine varieties admit of very little. Now is a good time for any-one willing to embark in border auricula culture to obtain seed and sow it. Do this in a shallow box or in broad shallow pans; have fine sandy soil on the surface; sow the seed very thinly and evenly, then press it in gently with the points of the fingers; strew a thin coating of the fine soil over all, water gently, then place in a frame or greenhouse, or in a warm place outdoors, covered with a bared light or large pieces of glass, and shade with newspaper. The seed coats are hard and take some time to soften, so that the plant germs can burst through. Seeds of last year should germinate within a month, but often some comes late, and plenty of patience is needed. Still the bulk of the seeds will give plants that will make nice strong ones to flower the following spring.—A. DEAN, *Kingston.*

NEW INVENTION.

Simplicity Thermometer-Holder and Indicator.—This novel and useful invention meets a long-felt want and entirely does away with the old practice of writing small labels and attaching them to the thermometer as guides to the man in charge with respect to the temperature required. The shape and manner of using the holder is explained by the illustration. The rack can be widened or narrowed according to the breadth of the thermometer used, while the movable pointers keep the instrument firm. Besides the "night" and "day" indicators, there is one at the top attached to the knob on which the thermometer hangs, and this can be used to indicate how high the temperature of the house may be allowed to rise by the aid of sun heat. The holder is ornamental as well as useful, and doubtless will in the near future be used in hospitals, churches, public halls, living rooms, &c., as well as in the glasshouses of private and nursery establishments. Mr. A. Outram, 7, Moore Park Road, Fulham, is the inventor, and from him the holders can be obtained at a reasonable price.



SIMPLICITY HOLDER.



SIMPLICITY HOLDER WITH THERMOMETER ATTACHED.

Plant and Seed Protectors.—Mr. William Cutler, of Constitution Hill, Birmingham, who has for a long period produced his series of plant and seed protectors to the satisfaction of many who have used them, is introducing a new patent pea or seed cover of galvanised iron, which deserves attention for its utility and inexpensiveness. The invention consists of a glazed span framework some twenty-four inches long by sixteen broad, provided at each corner with a spike-formed termination, which can be pressed into the ground to any needed depth. As the ends are quite open, a succession of covers can be ranged to any required length without the slightest interference with the protected vegetation, and sufficient air is admitted to exclude condensation. As the glazed roof is in sliding panels, movable at will, further ventilation is available whenever required.

ROSE SHOW FIXTURES IN 1898.

June 15 (Wednesday).—York.
,, 16 (Thursday).—Colchester and Isle of Wight (Carisbrook.)
,, 23 (Thursday).—Bath (N.R.S.) and Ryde.
,, 25 (Saturday).—Windsor.
,, 28 (Tuesday).—*Leeds, †Southampton, Sutton, and Westminster (R.H.S.)
,, 29 (Wednesday).—Canterbury, Croydon, and Richmond (Surrey).
,, 30 (Thursday).—Eltham, Gloucester, and Norwich.
July 2 (Saturday).—Crystal Palace (N.R.S.).
,, 5 (Tuesday).—Harrow and Hereford.
,, 6 (Wednesday).—Chelmsford, Ealing, Farningham, Hanley, Hitchin, Redhill (Reigate), and Tunbridge Wells.
,, 7 (Thursday) —Woodbridge.
,, 8 (Friday).—Ulverston.
,, 9 (Saturday).—Manchester.
,, 12 (Tuesday).—*Wolverhampton.
,, 13 (Wednesday).—Ipswich, Maidstone, and *Newcastle-on-Tyne.
,, 14 (Thursday).—Halifax (N.R.S.), Brentwood, Canterbury (Hospital Fund), and Helensburgh.
,, 16 (Saturday).—New Brighton.
,, 21 (Thursday).—Sidcup.
,, 26 (Tuesday).—Tibshelf.
,, 28 (Thursday).—Bedale.

* Shows lasting three days. † Shows lasting two days.

The next list of fixtures will appear early in June. In the meantime I shall be glad to receive the dates of any rose shows (or other horticultural exhibitions where roses form a leading feature) for insertion in that list.

Rosebank, Berkhamsted, Herts.

EDWARD MAWLEY.

ANSWERS TO CORRESPONDENTS

Editorial communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, &c., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning change of dates

Eucharis amazonica.—D. W. B., Malvern Wells: We hope in an early issue to deal with the matter you mention. Meanwhile we shall be glad to furnish you with any information you require upon the subject. We are always glad to receive letters of the kind you send.

Weed Killers.—J. G. W.: The majority of the weed killers in use are arsenical preparations, and therefore they should not only be used with ordinary care, but the vessels containing them should be kept under lock and key, where those only who are acquainted with their properties should have access to them.

Ficus macrophylla.—H. E. W., Willesden: This is the Australian Banyan or Moreton Bay fig. It is seldom grown in this country outside botanic gardens, but where there is room for it its deep-green and glossy foliage render a not unattractive plant. It is a species easily cultivated, and one that will grow in a stove, succeed in an intermediate house, or exist in a greenhouse. It does best in a warm greenhouse or intermediate house and is not very particular as to soil.

Propagating Petunias.—T. M. F., Warwick: The double petunias with which you are so pleased may be propagated by means of cuttings struck in August. Single forms may also be retained by this means if thought desirable, though seedlings are now so fine that it is hardly worth while to raise stock by means of cuttings. The cuttings may be inserted several together in pots of light sandy soil placed in a temperature of 60 degrees; here they will soon root, and should then be potted into three-inch pots. Harden off as quickly as is reasonable, and keep the plants in greenhouse or pit during the winter, potting them on in the spring.

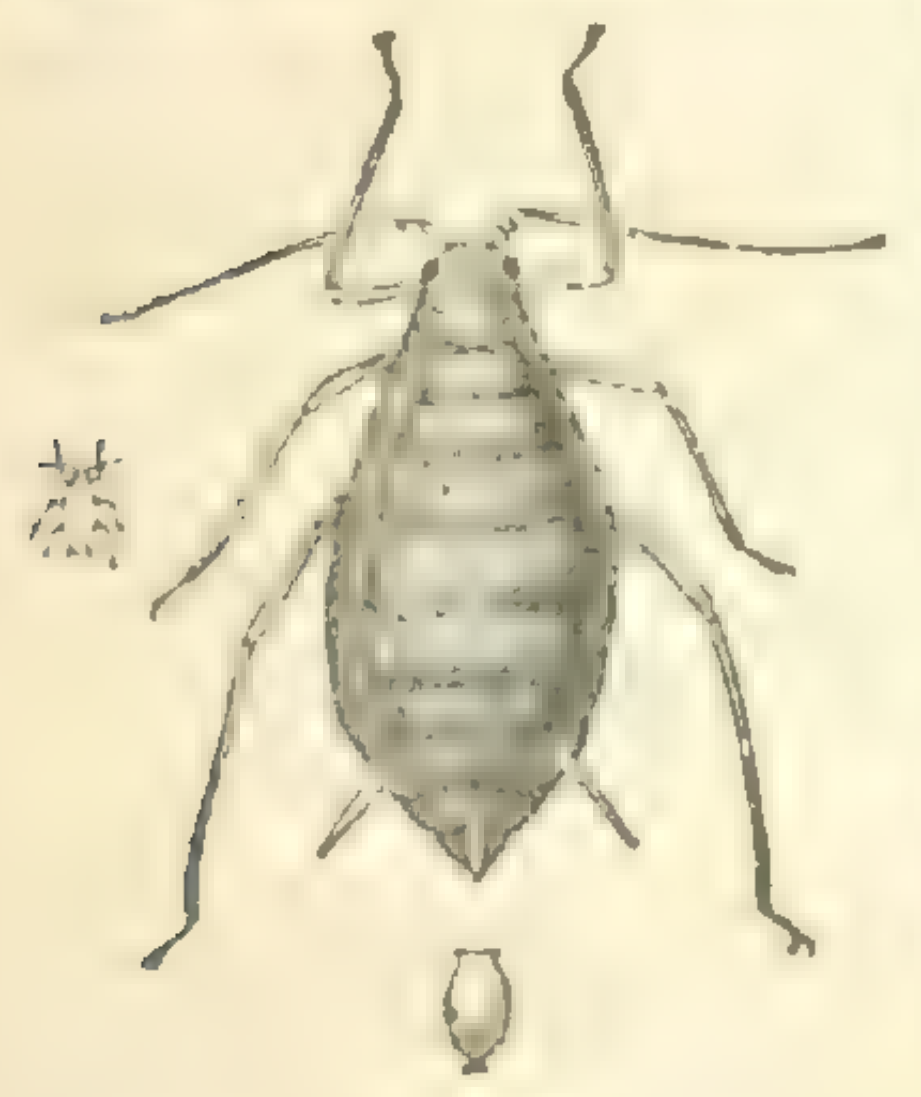
Caterpillar on Peaches.—P. O.: The caterpillar sent was in an advanced stage of decomposition when received, and consequently could not be recognised. It is one of a class known as "loopers," so called because the fore part of the body clings to a twig or leaf, while the centre forms an upward loop, thus dragging the hind part forward; this accomplished, the claw-like feet of the hind part grip the same twig, and the forward part and centre extends. This business is continually repeated, and forms the mode of locomotion. Hand picking will be the best remedy, and with a little patient perseverance the intruders may be cleared out. A cloth spread below the trees may also serve to trap any that fall if the branches are smartly tapped.

Lack of Flavour in Melons.—H. B., Leicester: The lack of flavour was due to two causes—too large a root run, and excesss of moisture when the fruits were ripening. Restrict the roots by means of slates or boards, and when the fruits are ripening reduce the water supply and do not damp down the frame at closing time. Raise the fruits upon clean inverted pots, so that they are under the full influence of all the sunlight that reaches the frame; give a moderate amount of air at this period, and supply water so that the roots only are moistened. You should also remember that some varieties of melons are more highly flavoured than others, but of course no variety will yield luscious fruits if improperly cultivated.

Strelitzia Reginæ.—B. B., Weston-super-Mare: This bold and curiously flowered plant is generally grown in a stove, but it can be even better accommodated in an intermediate, house. A greenhouse will suit it in the summer if more warmth is afforded during the winter. It has stout roots, and consequently needs fairly large pots and a substantial compost of loam, sand, and a little dried cow manure. Propagation is effected by division or the removal of the young sucker-like growths that spring up around the parent plant; potting or dividing should be done as early as possible after flowering, so that the plants become established before winter. Pot firmly, and afford newly potted plants some extra warmth until roots and growth are active, then the temperature may be lowered somewhat, and shade dispensed with altogether.

Globe Amaranth.—E. R., Greenwich: It is somewhat late to sow seeds of the Globe Amaranth, as the usual time for sowing is April. However, it is not too late for a good batch, especially as growth will be quick now. Sow the seed in pans of fine light soil, keep moist, and place in a temperature of from 60 to 70 degrees. Place the pans near the glass as soon as the seedlings appear, shade slightly from bright sunshine, and give a little air on favourable occasions. It is best to sow the seeds thinly, so that the seedlings are not quickly crowded; when two inches high pot the seedlings singly into three inch pots, using a rich loamy soil. Keep the batch close and shaded for a few days; then admit air carefully, and while maintaining a good growing atmosphere see that the plants are not drawn or weakened. Syringe the plants lightly twice a day, and keep the roots nicely moist. As soon as well rooted in these pots transfer the plants to those six or seven inches in diameter; drain carefully, and use a rich loamy compost. As soon as established in these, their flowering pots, an intermediate house or pit will suit them, giving plenty of air in fine and warm weather. When fully grown a somewhat cooler house will suit them better, as here, with a dryer atmosphere, the flowers will develop steadily and last a long time in first-rate condition. Fumigation will, perhaps, be necessary occasionally to keep down green fly. Place a neat stake to support the leading stem of each plant as soon as the final potting is completed.

Failure with Grapes.—E., Wimbledon: The damage is not due to thrips, but to rust and scalding, brought about most probably by an overheating of the vinery, followed by a rapid cooling. When from any cause a vinery becomes too hot, it is folly to open all the ventilators wide so as to quickly reduce the temperature; the more rational method is to admit air gradually, so that the temperature of foliage and berries becomes gradually lessened at the same time, and no chill is given. Sudden currants of cold air also cause the atmospheric moisture of the house to be deposited upon the berries, and this collecting into a drop acts as a lens and magnifies the sun's power, causing scalding. The great point is to air the vineries gradually, commencing early in the morning on bright and warm days; also damp floors and walls frequently in hot weather, as this serves to remedy excessively high temperature. Opening the front instead of the top ventilators is another cause of rust, when done ere the vines have considerably advanced and before mild weather prevails.



Turnip Aphis (Female).

Turnip Fly.—A. E., Winchester: In dry seasons the Turnip Fly (*Aphis rapæ*) often proves most destructive to turnips, and even in ordinary seasons it will put in an appearance if a week or two of dry, bright weather prevails. It varies in appearance, the wingless female being green or yellow in the summer, and dull red in the autumn; while the winged female is brownish black. A wash prepared by adding twenty-eight pound of soft soap and a pint of tobacco juice to a hundred gallons of water is a good remedy; but the most efficient is water to which paraffin has been added at the rate of two wine glassfuls to three gallons of water. To ensure the mixing of the paraffin oil with the water, add one part of soft soap to eight parts of water, and when brought to the boiling point add the paraffin, which will then thoroughly amalgamate with the water and soft soap. When properly diluted apply with a can to which a fine rose has been affixed or by means of a syringe.

Names of Plants.—H. E. W., Willesden: Ficus macrophylla.

W. O., Bristol: We cannot undertake to name florists' varieties of plants; send it to some nurseryman who grows extensively, such as Mr. C. Turner, of Slough, or Mr. H. J. Jones, Lewisham.

R. E. R., Nottingham: Pyrus malus; we should be glad to see a copy of the photograph to which you refer.

J. H., Fetcham: 1, Fritillaria delphinensis; 2, a form of Panax Victoriæ; 3, Pellionia Daveaneana.

L. M.: 1, Larix Europæa var.; 2, please send better specimen; 3, Juniperus chinensis; 4, Pinus Strobus; 5, not recognised; 6, Gentiana acaulis; 7, Sedum aizoideum variegatum; 8, Sibthorpia Europæa.

I. F., Yorks: 1, a mignonette, very poor form; 2, Alyssum saxatile; 3, a form of Prunus triloba.

A. B., Epping: Quite shrivelled when received, send again.

COMING EVENTS.

Alderley Edge and Wilmslow Horticultural Society, August 12 and 13; and November 11 and 12.
Ashbourne Horticultural Society, August 10.
Barnsley Chrysanthemum Show, November 17 and 18.
Bradford Chrysanthemum Show, November 11 and 12.
Dover Flower Show, August 17 and 18.
County of Gloucester and Cheltenham Horticultural Society, May 28 and 30; September 21.
Colchester Rose and Horticultural Society, June 16 and November 3.
Cranbrook Chrysanthemum Show, November 9 and 10.
Dorchester Chrysanthemum Society, November 2 and 3.
Grittleton and Alderton Flower Show, August 17.
Henley Horticultural Society, August 31.
Latton (Wilts) Flower Show, September 1.
Maintree Chrysanthemum Show, November 10.

UNITY IS STRENGTH may indeed be said with regard to Holloway's Pills and Ointment, for when used together, they are remarkable in their effects upon disease. No matter how stubborn the symptoms may be, they cannot long withstand these remedies. All sufferers, whom other treatment has failed to relieve, should try the celebrated Ointment, which will strengthen and cure them. The Pills recommend themselves to the attention of all sufferers. No injurious consequences can result from their use; no mistake can be made in their administration. In indigestion, confirmed dyspepsia, and chronic constipation, the most beneficial effects have been, and always must be, obtained from the wholesome power exerted by these purifying Pills over the digestion.—[Advt.]

MARKETS.

Covent Garden.

SUPPLIES of vegetables continue to improve, and there are fair supplies of fruit. Home-grown gooseberries have come along with a rush, but the only apples in the market are Tasmanian. Strawberries are cheapening as the season advances, and new potatos are daily becoming more plentiful.

FRUIT.—Tasmanian apples, 10s. to 18s. per case; pineapples, 2s. 6d. to 5s. 6d. each; bananas, 5s. to 9s. per bunch; Murcia oranges, 10s. to 14s. per case; Jaffas, 12s. to 16s. per box; English grapes, 2s. 6d. to 3s. 6d.; Jersey, 2s. 3d. to 3s.; Belgian, 1s. 3d. to 1s. 9d. per lb.; lemons, 6s to 15s. per case; English tomatos, 8d. to 10d. per lb.; Canary, 10d. to 1s. 4d. per tray, 3s. to 4s. per case; strawberries, 1s. to 1s. 9d. per punnet; Cornish gooseberries, 3s. to 3s. 6d. per small basket.

FLOWERS.—Arums, 3s. to 4s.; carnations, 1s. to 3s.; eucharis, 3s. to 4s.; gardenias, 1s. to 3s.; Lilium Harrisi, 3s. to 4s.; tea roses, 6d. to 1s.; pink roses, 3s. to 6s.; red roses, 2s. to 4s.; cattleyas, 6s. to 9s.; Odontoglossum crispum, 1s. 6d. to 4s.; and tuberoses, 1s. to 1s. 6d. per dozen blooms; Adiantum cuneatum, 4s. to 8s.; marguerites, 2s. to 4s.; narciss, various, 1s. to 3s.; daffodils, 1s. 6d. to 4s; tulips, 3s. to 6s.; mignonette, 2s. to 4s.; pelargoniums (scarlet), 4s. to 6s.; wallflowers, 2s. to 3s.; polyanthuses and cowslips, 1s. to 1s. 6d.; primroses, 9d. to 1s.; bluebells, 6d. to 8d.; and violets, 9d. to 3s. 6d. per dozen bunches; azaleas, 6d. to 9d.; stephanotis, 4s. to 6s.; lily of the valley, 6d. to 1s.; and pelargoniums, 4d. to 6d. per dozen sprays: bouvardias, 6d. to 8d.; white lilac, 3s. to 4s. per bunch.

VEGETABLES.—Egyptian onions, 6s. to 7s. 6d. per cwt.; English spring, 2s. to 3s. per dozen bunches; green peas, 3s. to 4s. per dozen pockets; asparagus, 1s. to 5s. per bundle; French beans (Madeira), 3s. to 3s. 6d. per basket; eschallots, 1s. 6d. to 2s.; garlic, 2s. 6d. to 3s. 6d.; mushrooms, 6s. to 8s. per 12 lb.; lettuce, 6d. to 1s.; cos, 2s.; endive, 1s. 4d. to 1s. 8d.; cucumbers, 2s. to 5s.; cauliflowers, 1s. to 2s. per dozen; parsley, 1s. 6d. to 1s. 9d.; mint, 3s. 6d. to 4s. 6d.; new carrots, 6s. to 7s.; turnips, 6s to 7s. per dozen bunches; spinach, 2s. per bushel; rhubarb, 2s. to 3s. per dozen bundles; Canary new potatos, 9s. to 12s.; Malta rounds, 8s. to 10s. per cwt.; Lisbon, 5s. 6d. to 6s. 6d. per box; French, 2d. to 2½d. per lb.

Borough Potato Market.

Old tubers are decreasing in supply, but owing to the large quantities of New Jersey potatos the demand is met, and fair prices are recorded. Dunbars, 130s. to 140s.; Scotch Magnums and Hebrons, 110s. to 120s.; Bruce Main-crop, Sutton's Regents, Reading Giant, and Saxons, 100s. to 110s per ton; Belgians and Germans, 4s. 9d. to 5s. 3d per bag. New—Maltese rounds, 9s. to 10s.; Teneriffe kidneys, 12s. to 13s.; Jersey, 24s. to 28s. per cwt.; Lisbon rounds, 5s. to 5s. 6d. per box.

Fruit Prospects in Wilts.—The fruit prospects here are at the present very rosy. I cannot remember ever seeing so much blossom upon the trees. Apples, pears, plums, damsons, cherries, apricots, peaches, gooseberries, and currants are loaded with bloom or fruit, and if climatic conditions continue to be favourable we shall have a magnificent crop. What few apples we had last year in the orchard were extra fine, and in point of keeping were good. I sent in the last dish of Cox's Orange on Easter day, April 10. We have several hundreds of apple trees, and all are showing beautifully. Peaches have set with freedom, so also have apricots, and this in spite of very low temperatures during the flowering period. Individual pear trees have been a wealth of bloom, notably Jargonelle with its huge clusters, Pitmaston Duchess, Marie Louise, Doyenne D'Ete, Doyenne du Comice, Comte de Lamy, Williams' Bon Chretien, Beurre Diel, &c. Apples on walls were beautiful, notably, Red Astrachan, Irish Peach, and Cox's Orange. Cherries were a wealth of blossom, and among the best were Bigarreau, May Duke, and Elton. The apricots that have set best are Large Yellow and Shipley.—W. A. COOK, *Compton Basset, Calne, Wilts.*

THE WEATHER DURING THE WEEK ENDING MAY 14, 1898.

The mean reading of the Barometer during the week at Greenwich was 29·55 inches, and that of the Thermometer 50°·7, the latter being 1°·0 below the week's average in the 50 years 1841—90. The direction of the wind was south-westerly, the horizontal movement of the air being 24 per cent. above the week's average in the 16 years 1860—75. The duration of registered bright sunshine in the week was 30·8 hours. The measured rainfall amounted to 0·54 of an inch.

ENGAGEMENTS FOR THE ENSUING WEEK.

MEETINGS.

TUESDAY, MAY 24.—Anniversary Meeting of the Linnean Society.

EPPS'S COCOAINE.

COCOA-NIB EXTRACT.

The choicest roasted nibs (broken-up beans) of the natural Cocoa on being subjected to powerful hydraulic pressure, give forth their excess of oil, leaving for use a finely-flavoured powder—"Cocoaine," a product which, when prepared with boiling water, has the consistence of tea, of which it is now, with many, beneficially taking the place. Its active principle being a gentle nerve stimulant, supplies the needed energy without unduly exciting the system. Sold only in labelled Tins. If unable to obtain it of your tradesman, a tin will be sent post free for 9 stamps.

WEST'S
PATENT
IVORINE
PLANT LABELS
NAME TO BE WRITTEN ON WITH ORDINARY LEAD PENCIL OR PEN AND INK.

THE "IVORINE" WRITING DISC

Being made of a specially prepared substance, having the properties of real ivory, is imperishable, and does not corrode or eat away, like wood and metal labels; and being ivory-white, when written upon it shows to perfection. And also, as the writing is on the Ivorine itself it is permanent, though washable, and does not become unreadable, as is the case with all painted labels, as the paint gets old. It is for all purposes, and will last a century, either in a greenhouse or out in a garden, and not only is it always ready for use, and may be written on both sides, but the name when written in pencil may be easily rubbed off, and so used as many times as desired.

Samples and Lists of the West's Patent Specialities post free.
Price, **9d.** per dozen; **8s.** per gross, Carriage Paid.
Supplied by all Nurserymen, Florists, &c.

THE THAMES BANK IRON CO.,

UPPER GROUND STREET, LONDON, S.E.

Telegraphic Address: HOT-WATER, LONDON. Telephone No., 763 HOP.

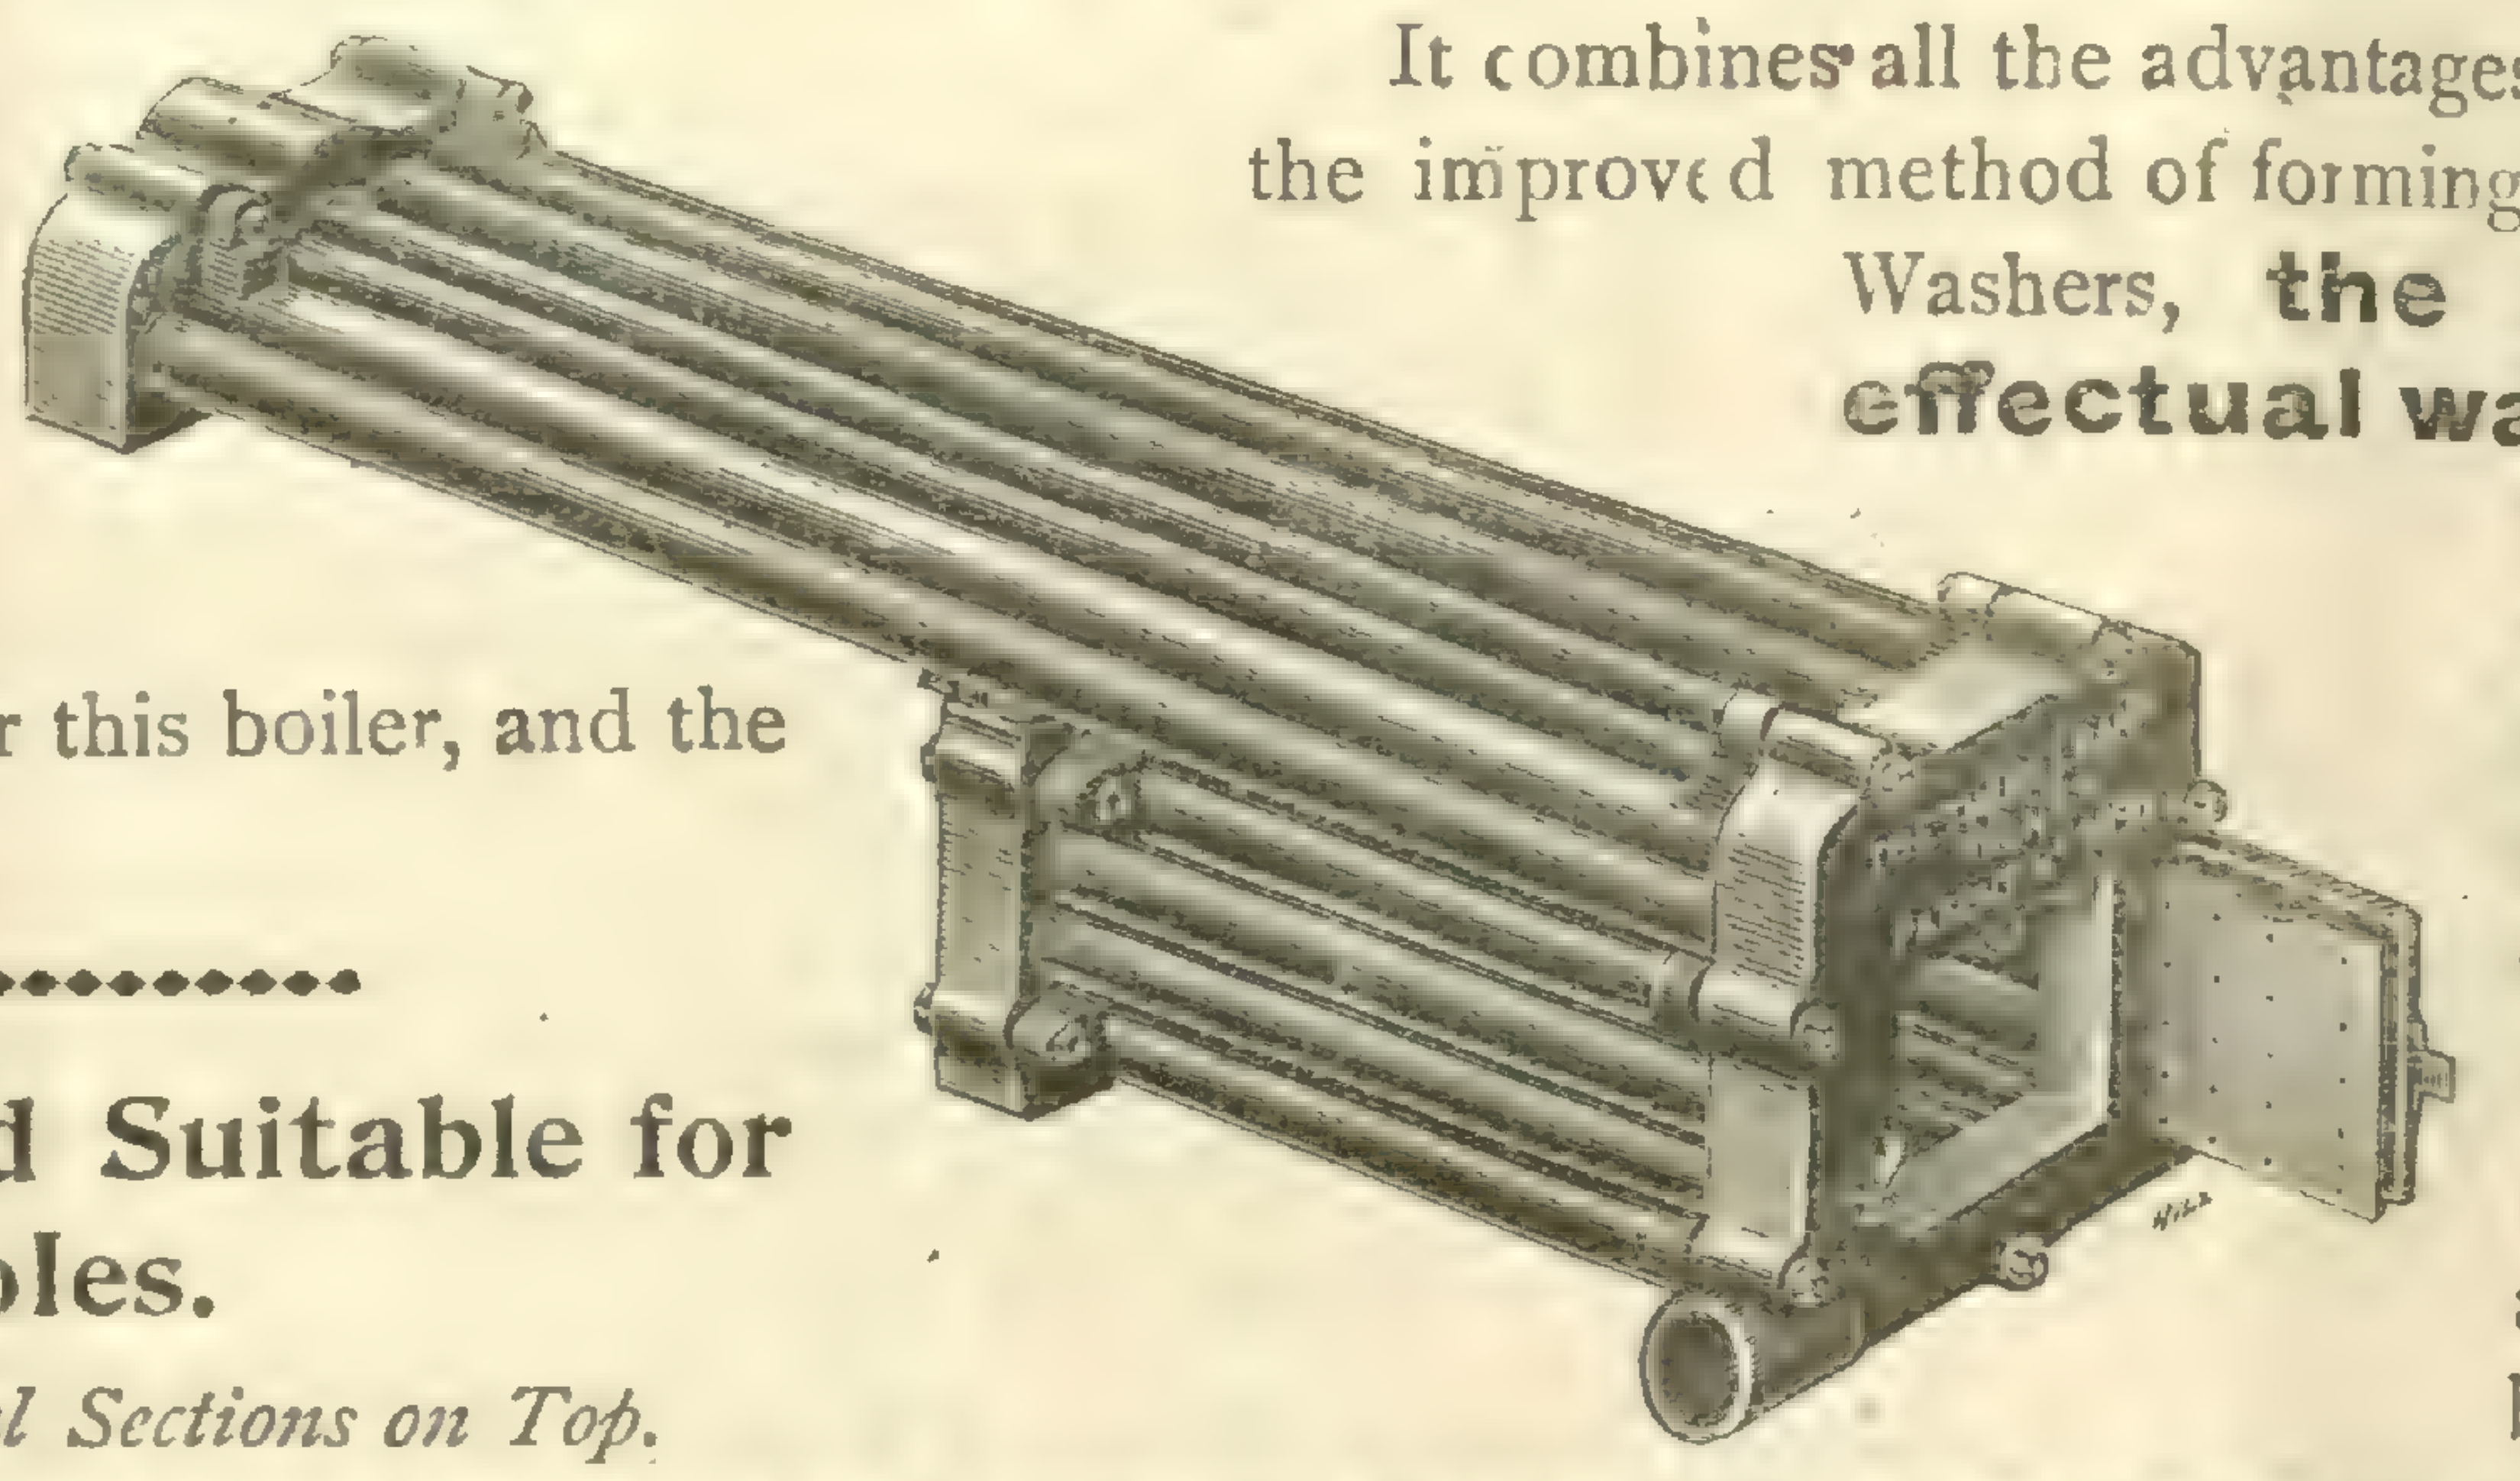
The New Horizontal Tubular Boiler.

(ORIGINAL MANUFACTURERS OF THIS CLASS OF BOILER.)

Supplied in several sizes for the last 40 years to the leading Horticulturists.

Several improvements have from time to time been introduced, including Water Bars, Furnace Door hung upon the front of Boiler, &c., as shown in illustration, thus making it complete in itself.

There has been a great demand for this boiler, and the success attending it has been general.



It combines all the advantages of its class so well known, and by the improved method of forming the joints—viz., with India Rubber Washers, **the old and too often ineffectual way of caulking the joints is entirely dispensed with.** It can be erected in a few hours, and may be relied upon as a thoroughly sound and good Hot-water Generator. It has been carefully tested in every possible way, more especially with regard to power and durability, and the result has been highly satisfactory.

Powerful, Economical, and Suitable for Shallow Stokeholes.

Also made with one or more Additional Sections on Top.

The Largest and Most Complete Stock of HOT-WATER BOILERS OF EVERY DESCRIPTION, PIPES, CONNECTIONS, VALVES, VENTILATING GEAR, &c. Inspection of same invited.

Hot-Water Apparatus erected complete. Iron Pipes for Gas and Water and General Sanitary Castings.

BOROUGH OF WIDNES.

QUEEN'S DIAMOND JUBILEE
COMMEMORATION.

The Commemoration Committee invite Competitive Designs for the laying out of a Park and Recreation Grounds at Appleton in the said Borough. The following premiums will be paid to the respective authors of the designs placed first, second, and third in order of merit:—1st, £36 15s.; 2nd, £10 10s.; 3rd, £5 5s. The conditions of the competition, with a plan of the site, may be obtained on applying to Mr. John S. Sinclair, A.M.I.C.E., Town Hall, Widnes, on payment of £1, which will be returned on receipt of Competitive Drawings, or on receipt of the conditions and plan, in case the applicant does not compete. Plans, &c., to be sent in addressed under motto to the undersigned by July 1, 1898.

H. S. OPPENHEIM,
Town Clerk,
Hon. Secretary.

Town Hall, Widnes.
May 12, 1898.

PRACTICAL LANDSCAPE GARDENING
and ESTATE DEVELOPMENT CO.

This Company undertakes to advise as to the laying out of gardens, the general improvement of landed property, and the development of building estates; to provide plans and estimates, and, for a fixed sum, to carry out all work incidental to the making of the smallest Villa garden as well as to the designing and execution of the most extended estate improvements.

It has a staff of experienced foremen, and all necessary plant.

No charge whatever is made for plans, which, however, remain the property of the Company unless the work is carried out by it.

All communications to be addressed to—

NEW HYBRID TREE TOMATO

(Quite distinct from any other variety).

This Tomato is of dwarf and sturdy habit, free from disease, requiring no support until the plant is very heavily laden with fruit. The earliest and most hardy of any Tomato for Outside Cultivation. The fruit is of good shape and size, smooth, deep crimson colour, and excellent flavour. Plants: three for 2s.; six for 3s.; or 5s. per dozen, free for cash with order.

ROBERT HOLMES, Norwich.

GREENHOUSE SALE (Off season).—7 X 5, 28/6, 38/6; 10 X 6, 42/-, 50/-; 14 X 6, 52/6, 65/-; 10 X 8, 52/6, 58/6; 14 X 10, 75/-, 88/6; 20 X 10, 87/6, £5/15/-. Frames, 8/9, 14/6, 22/6. Fowl Houses, 8/9, 10/9, 14/6.—Approval, HYPOLITE, Deptford.

1898 FORBES' CATALOGUE 1898

(over 150 pages—nearly 150 illustrations) of
FLORIST'S FLOWERS and HARDY BORDER PLANTS

is got up REGARDLESS of TROUBLE or EXPENSE, with the result that it is by UNANIMOUS CONSENT pronounced the most COMPREHENSIVE, most ACCURATE, most RELIABLE, most COMPLETE, and BEST EXTANT.

It gives full and ACCURATE DESCRIPTIONS of everything in the way of FLORIST'S FLOWERS, also COLOUR, HEIGHT, TIME of FLOWERING, and PRICE of all the best HARDY BORDER PLANTS, together with their ENGLISH or COMMON NAMES, and a mass of other VALUABLE INFORMATION that cannot be had elsewhere.

It is, in fact, a veritable REFERENCE-BOOK, invaluable to all growers of these plants, and should be in the hands of all intending purchasers. Free on application.

NOTES OF THE WEEK.

THE TEMPLE SHOW.

AS so well shown in our report, the anticipations to which we gave expression in our issue of the 21st inst. have been amply justified by the event, and the exhibition which during the past week has been held under the auspices of the Royal Horticultural Society in the gardens of the Inner Temple must be described as one of the most successful, horticulturally, of the series. Of the financial results we are not at the time of writing able to speak, but with the continuance of the weather which prevailed on the first and second days it is reasonable to hope that they may prove satisfactory. By these results the question as to whether it was wise to arrange the exhibition for the same week as the summer meeting at Epsom must be answered, but having regard to the fact that the great Whitsun exhibition at Manchester opened on the 27th, it is not unreasonable to assume that there would have been a manifest advantage in fixing the gathering for a week earlier. Regarded as a whole, the products were of a somewhat higher quality than usual, and orchids, roses, and caladiums have probably not been presented in larger numbers or in finer condition than on this occasion, while fruits and vegetables were exceptionally meritorious, and it was gratifying to observe that private growers contributed liberally to these two important sections of the exhibition. The arrangements represented a large amount of work on the part of the several officials engaged in planning and carrying out the details, and we should have been immensely gratified had their labours given more satisfactory results. The difficulties that have to be contended with in carrying out an exhibition of this magnitude under the conditions that obtain must be very great, but they can hardly be such as to prevent some change being made in the arrangement of the tents. Picturesque effect is perhaps difficult of accomplishment, but with the aid of a few large palms and tree ferns, and these should not be difficult to obtain, much of the flatness in the two principal tents might have been got rid of. Something should also be done to enable visitors to inspect the products in the long tents with a greater degree of comfort than is possible under the conditions that obtained, more particularly in relation to ventilation. In the matter of effect and the comfort with which the collections could be inspected, the exhibition necessarily suffers in coming so soon after the Ghent Quinquennial, and possibly the journalists who were present at that great gathering remembered with a tinge of sadness the courtesies they received there, more especially those from the genial, large-hearted president of the Ghent Society. However that may have been, the exhibition was so extensive and contained so much that was of interest in exemplifying the high position which horticulture has attained in this country, that we are anxious that in the matter of tasteful effect and the comfort of visitors the exhibitions of the leading horticultural society may be brought more into line with the great Continental gatherings.

FLOWERING TREES.

ALTHOUGH the season has not been favourable for the development of the flowers of hardy trees blooming in spring they have formed a procession of wondrous beauty, and again reminded us of their great value in the making of garden scenery. The year had hardly began to run its course before the garden was enlivened by the snow-white flowers of Amygdalus Davidiana alba, and these were followed in rapid succession by the delicate pink blossoms of the almond and the slightly tinted bloom of the purple-leaved plum. Later on came the single and double flowered cherries, which have no superiors in beauty; the various species and varieties of pyrus, of which so many handsome forms are at the command of the planter; and now the common laburnam is in its full glory, and as the elegant racemes are gently swayed by the winds the trees suggest to the imagination fountains of gold. The procession of flowering trees belonging to the spring is practically brought to a close by the single and double flowered thorns, which, if blooming less freely than for some years past, are sufficiently attractive to contribute materially to the enjoyment of the garden or park in which they have a place Much might be said in praise of the finest of the trees remarkable for the beauty of their flowers, and in these pages much has been written advocating an extension of their culture, and with, we are pleased to know, good effect. Thousands of trees of the more beautiful kinds have been planted as the direct result of the advice given editorially and by our valued coadjutors; but they have not as yet been planted so largely as we could wish, and more particularly in suburban gardens of comparatively small size. In these the finest only of the trees should be planted, and yet we see garden after garden filled with trees that are, comparatively speaking, so uninteresting and unattractive as to add but little to the enjoyment of the garden. Why this is so is not difficult to understand, and it will perhaps suffice to strongly advise owners of gardens of limited dimensions to root out at the proper season the elms, limes, sycamores, and other timber trees, and replace them with trees distinguished for the beauty of their flowers or elegance of aspect, and happily these two attributes are combined in many of the trees belonging to the class we now have in view. The owners of suburban gardens might also remember that in planting flowering trees for their own enjoyment they will contribute to the pleasure, it may be, of thousands who have no gardens of their own, or plots so small as not to afford space for trees of even moderate development. In the Kew Gardens district flowering trees have, in accordance with the fitness of things, been very largely planted, and the display of flowers during April and May in the gardens that skirt the principal roads is so surprisingly beautiful as to give rise to the wish that what has been accomplished at Kew might be attempted in other suburban districts.

WOMEN GARDENERS.

FROM a manifesto that has been issued by the East Cowes Horticultural Association it is evident the members of that body are greatly perturbed by the efforts that are being made in certain quarters to give women a horticultural education, and very indignant with the horticultural Press for not having given to these efforts the most uncompromising opposition. In the course of the manifesto, which has been published in one of the Isle of Wight weeklies, they say: "It is most astonishing to find that this question of women gardeners is allowed to proceed with, to our mind, its damaging effects, uncriticised by the gardening Press of this country." Proceeding, they state "it is ridiculous to suppose that a woman after receiving three years' training . . . has acquired all the knowledge either to conduct a well-kept private or public garden in all its cultural details." Then, after a tilt at the County Councils for allowing women to participate in the advantages resulting from the disbursement of the educational grant, so far as relates to horticulture, we are told that "If technical education grants are to eventually become the means whereby the hard-working gardener, after years of deep interest in and devotion to his profession, is to be supplanted by a youthful feminine population, the money thus granted had far better be diverted to other channels." These are the main points, and taking them in reverse order, we at once say that the last proposition is not so self-evident to us as it appears to have been to those responsible for the preparation of the manifesto. We, indeed, are wholly unable to accept it, for if "technical education grants" are to become the means, eventually or otherwise, of enabling girls in their teens to supplant hard-working men who have given many years of interest and devotion to the work of the garden, they are far too good to be diverted into other channels. Were they found to possess this miraculous power we should advocate their increase rather than their diversion, and strongly advise both men and boys to take full advantage of them, that they might not only be able to hold their own in the battle of life, but obtain results that under the existing state of things are properly regarded as impossibilities. These results, however, are not probable or possible, and we can assure our friends at East Cowes that they can pursue their avocations without the slightest fear of being supplanted by a "youthful feminine population." With the second proposition we are in full agreement, for as we have repeatedly stated in these pages, it is impossible for either man or woman to become in the time sufficiently acquainted with the details of the work of the garden to successfully manage it. With reference to the astonishment expressed by the association that the question of women gardeners has not been criticised by the gardening Press, we are compelled to observe that the members have failed to take full advantage of the opportunities they have for obtaining information. We have again and again stated in no hesitating terms that gardening as a means of livelihood is utterly unfitted for the general body of women. We have not suggested that women should be excluded from technical education classes in which gardening is taught, or that they should not have exactly the same opportunities as men for the acquisition of a knowledge of horticulture, and we have no intention of changing the position we have taken up on this question. We hold the opinion that women should be allowed exactly the same freedom as men in choosing their avocation; but in giving expression to this opinion we consider it our duty to point out, as we have done on previous occasions, that so great is the difference in the strength and constitutional peculiarities of the two sexes, women, so far as the management of the garden is concerned, cannot compete on equal terms with men.

Dryandra calophylla is a most interesting and handsome species of proteaceæ, and one that is extremely rare in cultivation. A specimen now flowering in the Temperate House at Kew is very attractive by reason of its long semi-pinnate leaves that are covered with a brownish tomentum when young; the young foliage reminds one forcibly of the common ceterach fronds. The flower head is central, with a mass of rose-tinted styles and stamens. The genus Dryandra commemorates Jonas Dryander, a distinguished Swedish botanist, who died in 1810, at a period when proteaceous plants were more commonly grown than now. The younger Aiton's edition of "Hortus Kewensis," published 1810, contains descriptions of nine species of this genus, almost all of them introduced by Peter Good, seven years previously. At least seven of the fifty species recorded have been figured in the *Botanical Magazine*, and D. calophylla, introduced in 1830, will soon be added to that number. It is by the kindness of Mr. James H. Veitch, F.L.S., that this species is now at Kew, for the plant was raised from seed found by him in his Australian travels, and sent to Kew in 1893.

Disease of Lilies.—The disease from which Lilium candidum, L. longifolium Harrisi, and some other of the lilies suffer has been sufficiently prevalent in this country of late years to justify considerable apprehension on the part of cultivators, but it does not appear to have been so destructive with us as in Bermuda and the United States. The attack of the disease is characterised by the spotting and distortion of the leaves and flowers, and usually the stunting of the plant. In America and Bermuda this malady, known as the Bermuda lily disease, frequently destroys from twenty to sixty per cent. of the crop. Amongst the causes of the disease are included worn-out soil, premature cutting of flowers, too early harvesting of the bulbs, carelessness in the selection of stock for propagating, bad treatment during forcing, and the ravages of insects. Investigations carried out on behalf of the United States Department of Agriculture indicate the disease to be due to a combination of these causes. Bulbs become weakened through improper selection and propagation, and this weakening is aggravated by attacks of mites and of certain fungi and bacteria. During forcing the bulbs may become weakened by over-watering, or by allowing the roots to get too dry and then using an excess of water; in such cases the leaves become badly diseased. The blotching and distortion of the foliage are often due to the direct attack of several species of aphides and of young mites, or to the injection of water into the leaves by syringing. To check the disease proper cultivation, selection, and propagation are recommended in order to improve the stock; suitable rotations will prevent the increase of mites and parasitic fungi. It is further advised that the stems should be left on the bulbs to secure proper ripening, and care should be exercised in planting, all injured bulbs being discarded. As far as practicable, injurious insects should be kept in check from the start, and continuous care should be bestowed upon watering and ventilating. Chemical fertilisers are recommended in preference to farmyard or natural manures.

Professor Michael Foster, secretary of the Royal Society and Professor of Physiology at Cambridge University, has been elected president of the British Association for the meeting that will be held at Dover next year.

Roses at Richmond.—A decade or so since roses formed such an important and attractive feature of the exhibitions of the Richmond Horticultural Society that it has been matter for regret that of late years they have not, from various reasons, been adequately represented. We are glad to learn from Mr. Algernon Chancellor, the honorary secretary, that with a view to revive the glories of this section of the society's shows the Mayor and Mayoress of Richmond (Councillor and Mrs. Albert Chancellor) have presented a valuable challenge cup for roses, to be competed for at the exhibition to be held on Wednesday, June 29.

The Worshipful Company of Gardeners have now at least one Freeman who was freeborn, and the interesting ceremony of christening this young gentleman was conducted in the chapel of the British Home for Incurables, Streatham, on Tuesday, the 23rd inst. The new freeman is Robert Cecil Sherwood Gofton-Salmond, son of the secretary of the Gardeners' Company. His God-parents were the Hon. Mrs. Evelyn Cecil, N. N. Sherwood, Esq., and Herbert Haynes, Esq.; the officiating clergy were the Rev. C. C. Gosselin, the Rev. W. Wilks, and the Rev. Canon Allen Edwards. The ceremony was an elaborate affair, and the decorations in the chapel, carried out in white flowering plants and palms by Messrs. J. Peed and Sons, Roupell Park Nurseries, Norwood, were particularly handsome and beautiful.

THE GREAT TEMPLE SHOW.

THE eleventh of the series of grand exhibitions held at the Inner Temple Gardens, by the Royal Horticultural Society, took place on May 25, 26, and 27. During the week the chief topic of conversation in the horticultural world has been the Temple Show, and very numerous have been the comments made upon the unfortunate circumstance of the Derby being run on the opening day, while not a few expressed their regret that the great Whit-week Show at Manchester compelled them to leave the metropolis much sooner than they wished.

In point of general excellence the present Temple Show has never been exceeded, for, in spite of the recent dull weather, everything on view was in good condition; indeed some exhibits that reached the Inner Temple Gardens were rejected because their presence would have detracted from the prevailing excellence. In extent the show scarcely differs from those of late years, as it is impossible to increase the space under cover. The available space for exhibits under the five large marquees is about 12,000 square feet, but in addition to this there were several extensive and handsome arrangements of hardy ornamental trees and shrubs arranged in the open, where they were greatly appreciated and looked well.

The principal occupants of the tent nearest the entrance (No. 1) were gloxinias, liliums, cut roses, carnations, hard-wooded plants, and miscellaneous cut flowers. Tent No. 2 contained the various collections of fruits and vegetables, both cut and in pots, bulbous plants, streptocarpus, and a big bank of brilliant phyllocacti. Ferns formed a leading feature in No. 3, with surrounding banks of tuberous begonias and gloxinias; here also were arranged the floral designs and groups of herbaceous plants. In tent No. 4, the large one from which the larger orchid tent is reached, presented a somewhat different appearance this season than usual, for instead of central tiers of staging there were groups of pæonies, pyrethrums, roses, clematis, crotons, maples, and azaleas down the centre, and arranged on the ground. On the side stages were orchids from various sources, including a handsome set from Brussels, calceolarias, cannas, ferns, and anthuriums. In the big marquee the orchids proved the great attraction, as usual, though this year there was a slight falling off in the extent and number of orchid exhibits and exhibitors, notable absentees being Baron Sir Henry Schröder and Wellbore Ellis, Esq. Orchids and new plants filled the centre, and a fine setting for these was formed by the magnificent groups arranged all round; roses in pots came from the leading growers, fruit trees from eminent cultivators, laden with ripe fruit, clematis, three grand lots of exquisite caladiums, banks of rhododendrons, palms, choice hardy plants, carnations. This brief *résumé* will give readers some idea of how the tents are filled, while our detailed report and illustrations taken on the spot will further assist those not fortunate enough to be present to gain a fair idea of the extent, composition, and quality of the exhibition.

It should be added that the exhibitors number about three over a hundred, exclusive of those who stage but one or two new or rare plants for special awards. Considering the size of the display as a whole this is not an extraordinary number of exhibitors, but nevertheless it is twenty more than last year, and there are quite a goodly number of new exhibitors. New plants were both numerous and good, and those who were not present at the Ghent Quinquennial of this year found many pleasant surprises at the Temple in the way of distinct and meritorious novelties. As previously stated in these columns, had all the exhibitors been granted the space they asked for it would have required at least three times the available area to hold their exhibits. It will be understood from this that the R.H.S. Council had no easy task to adjust the spacing, and, having made the adjustment, they rejected all entries sent after the date fixed. The management of the show was in the hands of the Rev. W. Wilks (secretary, R.H.S.) and Mr. S. T. Wright (superintendent), who were ably assisted by Mr. T. Humphreys (assistant superintendent) and Mr. T. W. Turner (foreman), from the Chiswick Gardens.

Orchids.

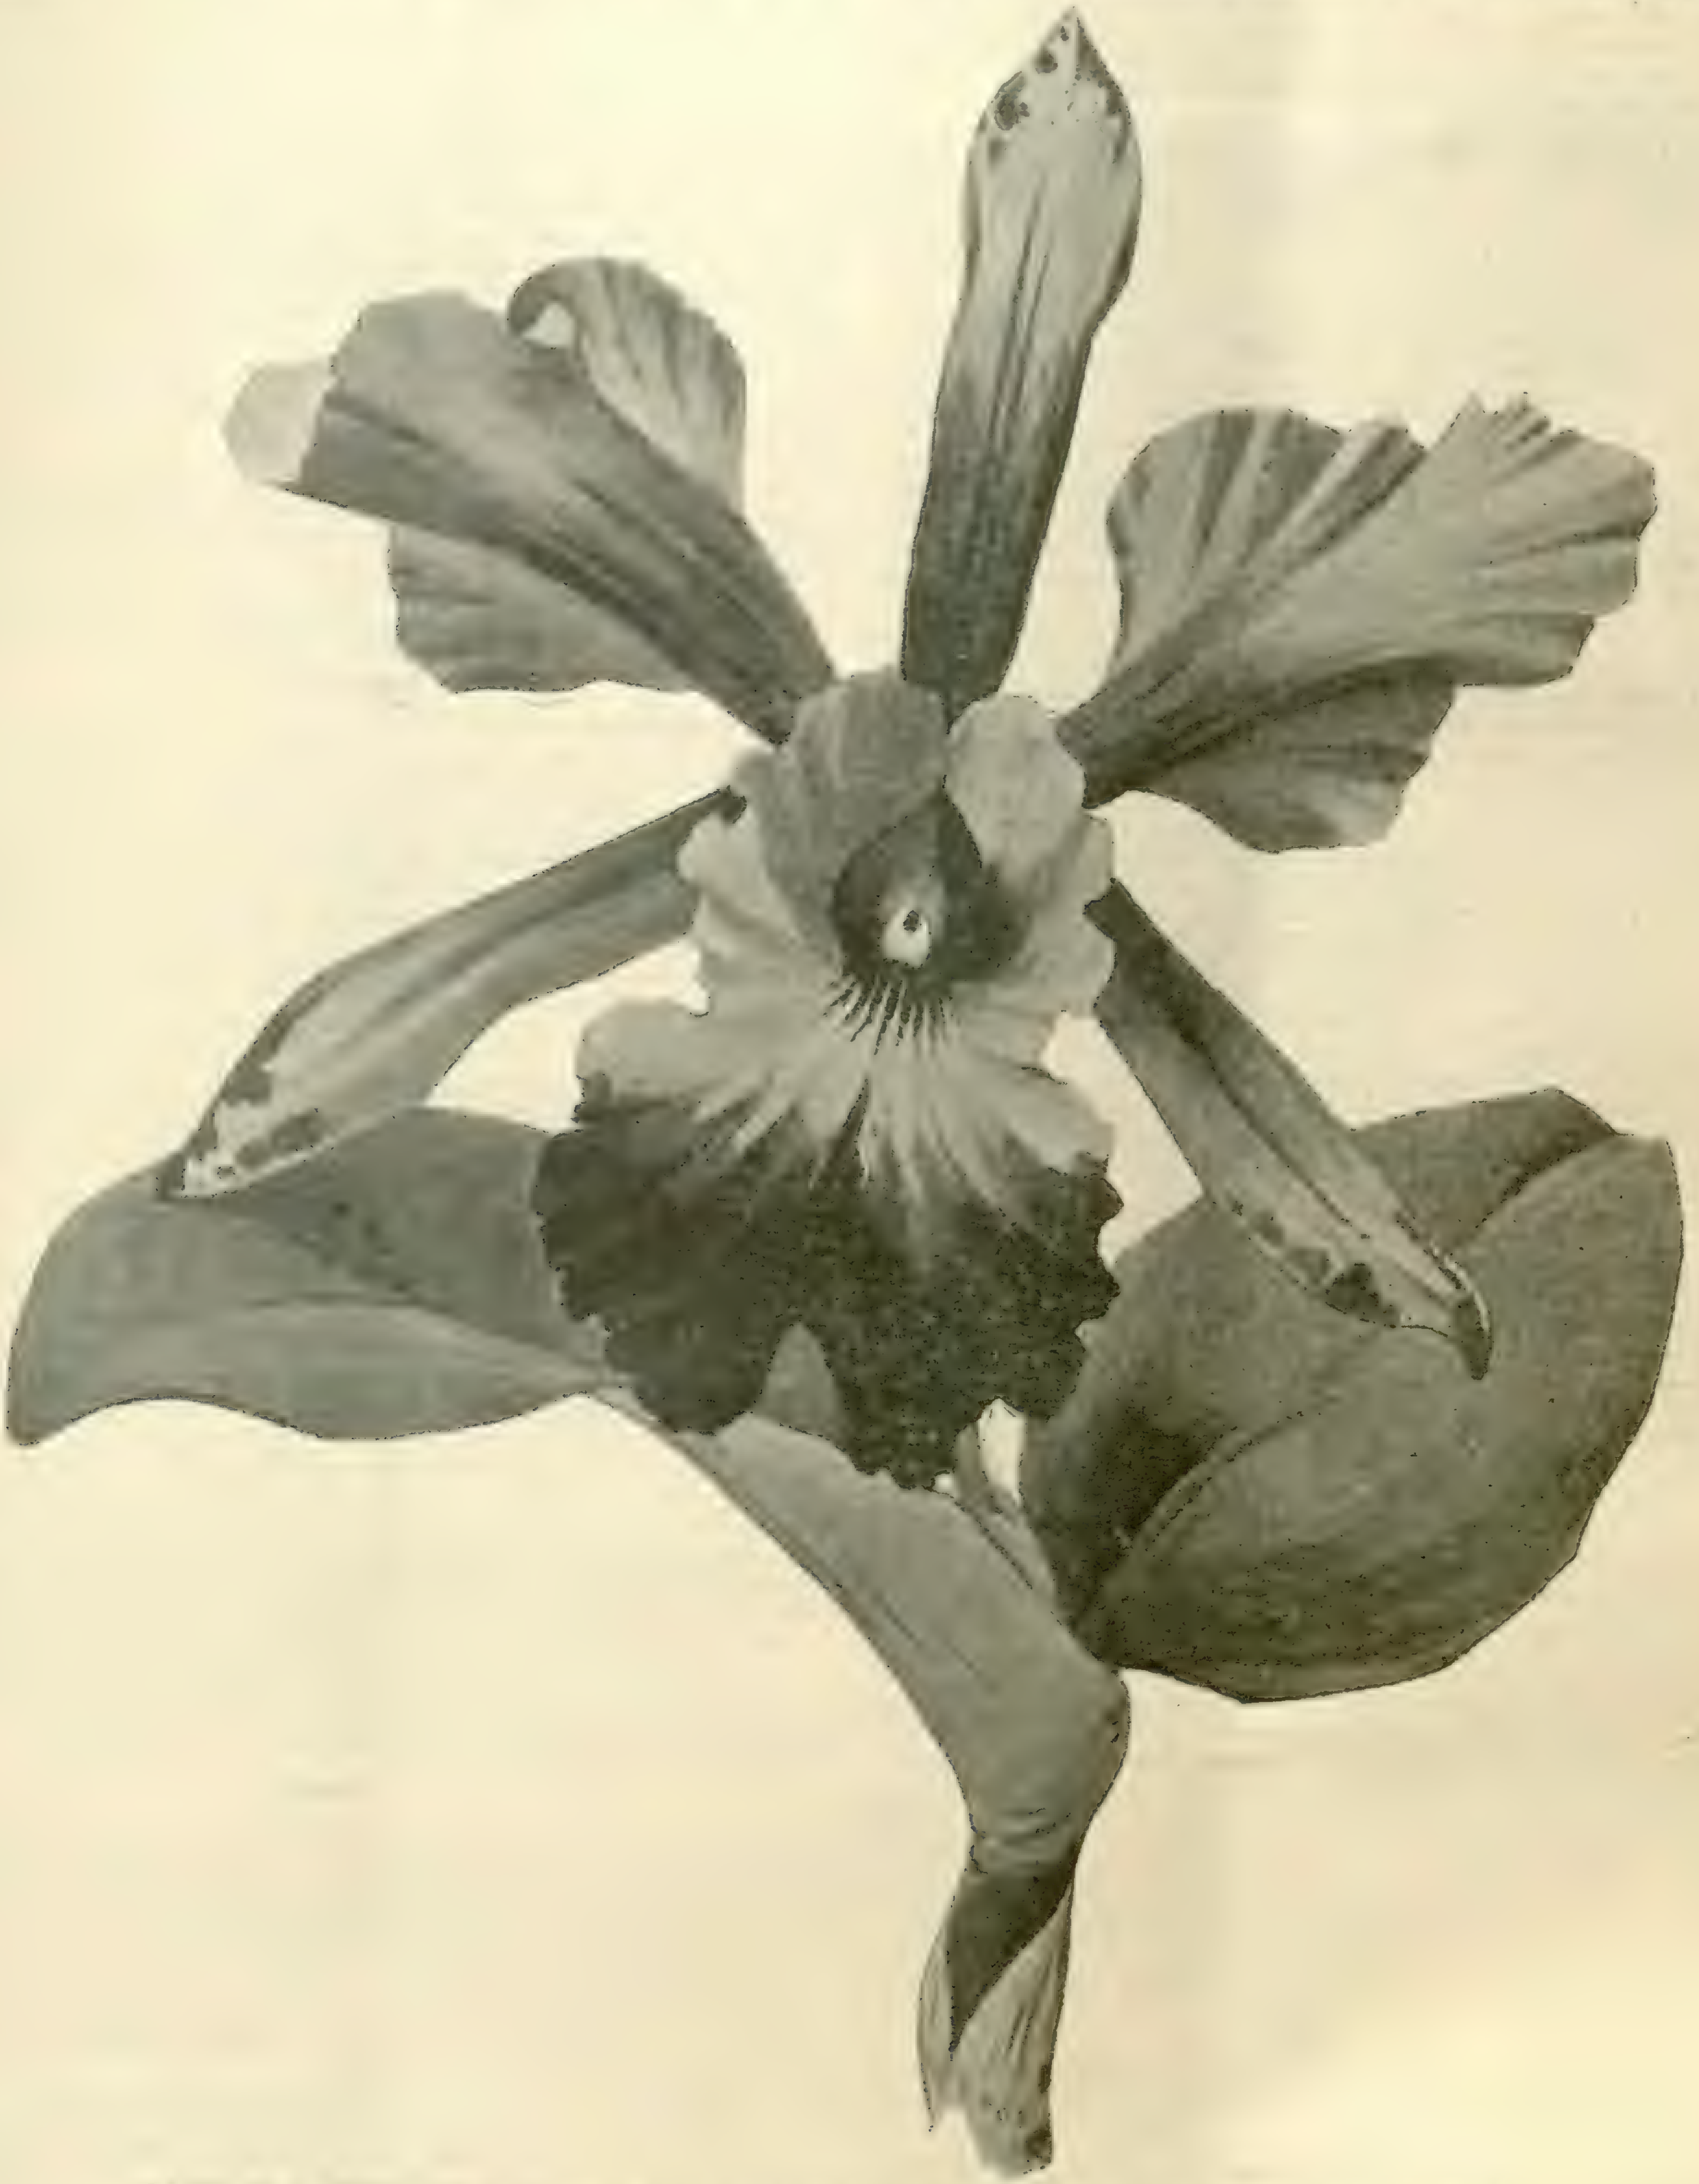
Orchids were the great feature, though scarcely so abundant as usual. Sir Trevor Lawrence's able orchid grower, Mr. W. H. White, arranged a very fine lot of orchids in the position usually occupied by Baron Schröder's collection. It was a large display and contained fine forms of such beautiful orchids as Cattleya Mendeli, C. Mossiæ, Lælia purpurata, Miltonia vexillaria, Cymbidium Lowianum, Oncidium ampliatum majus, and Odontoglossum crispum. Among rare subjects were Schomburgkia tibicinus, with eight fine blooms; Cypripedium Olenus Burford var., with two huge purple spotted flowers on one scape; Cattleya Skinneri alba, a pretty plant with half a dozen flowers; Cattleya Parthenia, with two charming flowers; the curious Colax jugosa, carrying fine pretty bluish-lipped flowers; Odontoglossum luteo-purpureum radiatum, Epiphronitis Veitchi, Renanthera Imschootiana, with blood-red flowers, the curious Dendrobium O'Brienianum striatum, with depending spikes; Macodes petola, Dendrobium Parishi albens, Cattleya Wagneri, a handsome plant; Masdevallia Shuttryana, Saccolabium miniatum, a scarlet-flowered species; the "Blue Dendrobium," D. Victoria Reginæ, Bulbophyllum saltatorium, the delicately coloured Aganisia cærulea, and Maxillaria grandiflora. There were fine large and freely-flowered specimens of Cypripedium superbienis, C. grande, C. barbatum, C. Eleanor, C. Lawrencianum, and C. Swannianum superbum. Masdevallias, epidendrums, and other orchids in variety, assisted to make up an excellent exhibit with the aid of a suitable backing and groundwork of palms and ferns.

A very pretty exhibit of orchids was staged by Mr. W. H. Young, orchid grower to Sir Frederick Wigan, Clare Lawn, East Sheen; this display had a frontage of about fifteen feet, and was a bold exhibit, in which were numerous splendid examples of Cymbidium Lowianum and several large plants of first-rate forms of the popular Lælia purpurata; conspicuous and rare orchids set out among a host of miltonias, odontoglots, masdevallias, and cattleyas, were Cattleya intermedia Parthenia with four chaste blooms; C. Skinneri alba, with about two dozen flowers, Aerides crispum Warneri, the tiny and quaint Eria extinctoria, Disa Kewensis, Odontoglossum polyxanthum grandiflorum, O. Ruckerianum and a famous light form of O. crispum, Aerides Fieldingi, and Lælia purpurata Russelliana. This group also contained Dendrobium Victoria Reginæ, the [illegible] Cypripidium callosum Sanderæ, and C. Kerchoveanum, var. W. H. Young, a cross between C. Curtisi and C. barbatum; the front of the group consisted of drooping spikes of the fragrant Odontoglossum citrosmum. Mr. G. Wythes, gardener to Earl Percy, Syon House, Brentford, staged a handsome lot of orchids, his group containing a much larger variety than on former occasions; in the centre were large specimens of Cymbidium Lowianum, Dendrobium Pierardi, Cœlogyne Dayana, Odontoglossum Edwardi, and O. Reichenheimei; these and several freely-flowered Thunia Marshalliana were flanked by small groups of Cattleya Mendeli and C. Mossiæ, and higher up by specimens of Cypripedium barbatum, Dendrobium thyrsiflorum, Vanda trees, and Oncidium Marshallianum; ferns and palms were used with great effect here, and the front fringe of panicum was an excellent idea. Mr. M. S. Cooke, Kingston Hill, Surrey, showed a small group of orchids, consisting chiefly of forms of Odontoglossum crispum, [illegible] vexillaria, and Cattleya Mendelli; among the numerous examples of these we noted good specimens of Cypripedium Carteri, Cattleya Schillerianum, Lælia grandis tenebrosa, Odontoglossum polyxanthum, and Cochlioda sanguinea.

A brilliant collection of orchids was that from Mr. J. Cypher, Queen's Road, Cheltenham. It was an extensive exhibit of freely-flowered plants admirably arranged. Lælia purpurata was grandly represented, the form named L. p. atropurpurea being extremely handsome and distinct; L. p. Russelliana was also evident; Cattleya Skinneri gave fine bits of colour, as also did the long spikes of Dendrobium Phalænopsis and Cattleya citrina; Masdevallia Schlimi, M. tovarensis, Cypripedium Exul, Cattleya Acklandiæ, C. Schilleriana, Cypripedium Rothschildeanum, Cattleya Lawrenceana, Oncidium Krameri, and O. Marshallianum were other superb and interesting orchids that attracted considerable attention; Odontoglossum nebulosum and Thunia alba were also very good.

Messrs. F. Sander and Co., St. Albans, had a grand display of orchids and new plants, occupying the whole end of the centre of the large marquee. On one side there was a beautiful collection of odontoglossums, mostly forms of O. crispum, but all excellent, either for good form, colour, or spotting, the spikes robust, and flowers most substantial; O. luteo-purpureum, O. Ruckerianum, O. Halli in variety, and D. Harryana were present in quantity, and their dark flowers contrasted finely with those of O. crispum. Here also were fine forms and plants of Lælia purpurata, Cypripedium conco-bellatulum, Cattleya Mendeli in variety, and the exquisite Zygopetalum Perrenondi. On the opposite side cattleyas were most in evidence with C. Wagneri, very conspicuous, and carrying four beautiful flowers; a great mass of Oncidium ampliatum majus, and a large example of Cœlogyne Dayana, with a number of drooping racemes, occupied posts of honour with Masdevallia Veitchi grandiflora, Cypripedium bellatulum, C. callosum Sanderæ, Lycaste locusta (Sander's var.), Cypripedium Mastersianum with about three dozen flowers, C. macrochilum giganteum, and C. Doncasterianum inversum. Cattleya Skinneri alba and Sobralia macrantha alba were albinos of special note in this large display. In a tasteful group arranged by Mr. A. Hislop, gardener to H. S. Leon, Esq., Bletchley Park, Bletchley, there was a small set of grandly-flowered Vanda teres, with a lovely white sepaled form of Lælia purpurata, and a three-flowered plant of the brilliant Cattleya speciosissima; some lovely forms of Odontoglossum crispum were tastefully disposed among Cattleya Skinneri, C. Schroderæ, and C. Mendeli; a few cypripedes, Oncidium concolor, Epidendrum radicans, and Vanda tricolor were also present in good form.

A glorious group of orchids came from Messrs. Charlesworth and Co., Heaton, Bradford, and not a little of the beauty of the exhibit was due to the liberal use of maidenhair fern among the plants and a backing of fairly dense palms. Three groups of golden oncidiums, O. ompliatus majus and O. Marshallianum, were staged along the top, and had the pretty effect of chains of gold; around these were grand masses of charming forms of Odontoglossum crispum and O. Pescatorei,



CATTLEYA FERNAND DEVIS, F.C.C. TEMPLE SHOW. (Flowers pale rose and rich amethyst.)

and small groups of Lælia purpurata in splendid form. Cattleya Skinneri and Miltonia vexillaria were not only represented by charming varieties richly coloured, but by goodly specimens. Phaius Cooksoni, Masdevallia Veitchi grandiflora, Cattleya Mendeli, Odontoglossum luteo-purpureum, and Dendrobium Dearei contributed to the brightness and interest of the exhibit, but, more than all else, the new hybrids arrested attention. The chief of these were Cattleya Fernand Devis, a beautiful and bold hybrid raised by crossing Cattleya Acklandiæ and C. gigas; it has broad blush sepals and petals, and a spreading carmine-purple apex to the lip. Lælio-Cattleya radiata has been obtained by crossing L. purpurata and Cattleya dolosa, has much of the appearance of the former, but has a more compact flower. L.-c. Admiral Dewey is a lovely hybrid between Cattleya Warneri formosa and Lælia elegans Mastersi; it has bold lilac segments and a glorious labellum that ends in a rich crimson-purple apex; this carried four fine flowers, each about seven inches across. Cattleya Lord Masham (C. Loddigesi and C. superba) is distinct, and so is the brilliant Lælia cinna-brosa, a pretty hybrid between L. cinnabarina and L. tenebrosa.

Forms of Vanda tricolor were conspicuous in the collection of orchids staged by Messrs. B. S. Williams and Son, Holloway; they formed a fine screen against the background of palms, and served to heighten the effect of Cymbidium Lowianum, Lælia purpurata, Oncidium concolor, O. Marshallianum, Odontoglossum crispum in great variety, Miltonia vexillaria in abundance, Lælio-cattleya Latona, Anguloa Clowesi, the interesting L.-c. intermedio-flava, Cattleya Mendeli, rich forms, calanthes, and cypripedes. A small group of scarlet odontoglossum was the contribution of Mr. W. Stevens, gardener to W. W. Thompson, Esq , Walton Grange, Stone, Staffs.; O. excellens, var. Letty Lind, with branching spikes of light flowers; O. crispum Lily, rosy with crimson dots; O. crispum, capartianum, with brownish red blotches in the centre of each segment; O. crispum Dorothy, pretty with light blotches on the sepals; O. tripudians, O. crispum Thompsonianum, large, with deep crimson blotches, and O. c. fastuosum, an exquisitely-formed unspotted variety was the most beautiful sorts sent. Mr. J. O. Clarke, gardener to Ludwig Mond, Esq., 20, Avenue Boad, Regent's Park, arranged a small group of orchids, showing some pretty light forms of Miltonia vexillaria, good Cymbidium Lowianum vars., the fragrant Odontoglossum citrosmum, and several choice forms of cattleya and Mendeli

A wonderfully choice selection of orchids was tastefully arrayed by Messrs. Hugh Low and Co., Bush Hill Park, Enfield; the cattleyas were a beautiful lot, and naturally almost entirely forms of C. Mendeli and C. Mossiæ; besides these there were an abundance of spikes of the best forms of Odontoglossum crispum and Lælia purpurata. Especially rare and choice orchids in this handsome group were Lælio-cattleya elegans Lowiæ, with a crimson-purple apex to the lip; Odontoglossum crispum Dieudonné, a sweetly pretty form with intense spots; O.-c. In Memoriam W. E. Gladstone, with reddish-brown blotches; Cattleya Wagneri, C. Mossiæ Reineckiana, very beautiful; Cypripedium Gertrude Hollington, C. Rothschildeanum, Bulbophyllum Claptonense, Miltonia Bleuiana, and Cirrhopetalum Colletti. The Messrs. Low and Co. show no falling off in their orchids either in the matter of cultivation or excellence of variety. In the No. 4 tent Messrs. W. L. Lewis and Co. made an extensive display of beautiful orchids; it was a grand collection of Lælia purpurata, Cattleya Mendeli, Odontoglossum crispum, Oncidium ampliatum majus, and other popular orchids. Cypripedium Evenor Southgate var. was a conspicuous plant, with two flowers; Cattleya Schilleriana, a beautiful form of C. intermedia, Oncidium spilopterum, Cypripedium grande atratum, C. Gertrude Hollington, Southgate var., Phalænopsis amabilis, and a huge flowered variety of Cattleya Mendeli named Amelia were the most notable choice forms, not omitting a three flowered scape of Cypripedium Rothschildeanum.

A wonderfully pretty and elegant collection of odontoglossums came from Messrs. Linden and Co., Brussels; the strength of spikes, broad and substantial blooms, together with robust foliage, rendered this a most interesting exhibit. In addition to this was the wonderful diversity of variety in colour and spotting. O. crispum zebrinum, finely spotted; O. c. deliciosum, with big, reddish blotches; O. c. umbellum, curiously coloured; O. c. decorum, pure white, with a few large and intense spots; O. Pescatorei Alicise, with violet-purple spots; O Wilckeanum illustre; O. W. rufum, with brown markings; O. W. excellens, O. W. spectabile, and O. polyxanthum expansum were among the leading forms. A great beauty not to be omitted is O. venustum, a natural hybrid between O. crispum and O. Hunnewellianum, was a centre of interest by reason of its good form and free red-spotting all over the waved segments. There were several hundred grand spikes of odontoglossums, and a small group of Cypripedium Lawrenceanum grandiflorum in addition, making a splendid exhibit, to come from such a distance. A small lot of rare and beautiful orchids was contributed by Mr. Jules Hye-Leysen, 117, Conpure, Ghent; Miltonia Bleueana rosea gigantea was a grand orchid with immense blooms; Odontoglossum luteo-purpureum, var. Vuylstekianum, with yellow flowers; O. sceptrum, a fine form; O. cordato-crispum, Cypripedium Leysenianum, and Lælio-cattleya Hippolyta were all in good form and greatly admired.

Mons. A. Madoux, Anderghem, sent a few orchids, but these were staged too near a mass of begonias to be effective. Odontoglossum Charlesianum, a hybrid crispum form, prettily and heavily spotted, was a great feature, and this was surrounded by some excellent forms of Cattleya Mossiæ, C. Mendeli, Odontoglossum crispum, and a good specimen of Lælia Latona superba, besides a specimen of Dendrobium Victoria Reginæ. Messrs. J. Backhouse and Son, York, showed a few orchids arranged with some stove plants; Lælia purpurata, Miltonia vexillaria, odontoglossum crispum, O. polyxanthum, and Cypripedium Rothschildeanum were conspicuously good, staged amid ferns, miconias, Asparagus Sprengeri, &c.

Roses.

Roses constituted one of the most important and attractive features of the exhibition, and proved of much interest to the general body of exhibitors. Messrs. William Paul and Son, Waltham Cross, Herts, exhibited a magnificent group not less remarkable for the taste evinced in the arrangement than for the ample development of the leafage and the high quality of the blooms. Standards and pyramids were remarkably good, and judiciously interspersed amongst the bush specimens added materially to the general effect. Especially noteworthy were the examples of Aurora, an exceedingly beautiful hybrid tea with large finely-formed flowers of a glowing pink hue; Star of Waltham, Crimson Queen, Madame Lacharme, Mrs. John Laing, Medea, Corinna, Duke of York, one of the most beautiful of the China roses, Perle d'Or, Sylphe, Clio, Beaute Inconstante, Crimson Rambler (especially effective in a standard form), Maman Cochet. Cut roses were admirably shown by the firm, both in boxes and baskets; the basket filled with Clio, Augustine Guinnoiseau, Duke of York, and Crimson Queen, all of which have been raised at Waltham Cross, were especially beautiful.

The end of the large tent was occupied by a fine bank of roses from Mr. Charles Turner, Slough. The group consisted chiefly of dwarf bush specimens, all of which were well flowered and distinguished by an amplitude of foliage. Especially deserving of mention were the specimens of La France, Celine Forestier, Crimson Rambler, Camille Bernardin, Francisca Kruger, Madame Abel Chantenay, Juno, an old but beautiful variety which has long been grown with great success at Slough, Souvenir de Madame E. Verdier, Marie Baumann, Madame Lacharme, The Bride, Madame Victor Verdier, Madame de Watteville.

Messrs. Paul and Son occupied one of the lower corners of the big tent with a group of standard and dwarf specimens of surprising beauty. Of the many fine examples, special mention must be made of those of Captain Hayward, Madame de Watteville, Ulrich Brunner, Madame A. Chantenay, Rev. Alan Cheales, a comparatively new hybrid perpetual, especially good in standard form, as was so strikingly exemplified in the collection, and Crimson Rambler. Messrs. Paul and Son also exhibited two beautiful varieties raised from Crimson Rambler, namely, Psyche, a charming blush-coloured rose, of which a description has been already given in these pages, and Diana, a very distinct variety, with white rosette-like flowers, which are produced in large clusters, as in the case of its parent.

A small but attractive collection of roses was shown by Messrs. Frank Cant and Co., Colchester, in the tent adjoining the large marquee. All the plants were well grown and admirably flowered, but the most noteworthy were the standards of Niphetos, Kaiserin Augusta, Victoria, Souvenir de S. A. Prince, Madame Falcot, and Crimson Rambler. Messrs. F. Cant and Co. also had several examples of Thalia, popularly known both in Europe and America as the White Rambler, Mr. W. Rumsey contributed a group of roses in pots, which, arranged at one end of the tent adjoining the marquee, was very attractive. As in other collections, standards were used with good effect in association with bush-trained specimens, and afforded another object lesson on their usefulness in the conservatory. Some of the best standards were those of Mrs. Rumsey, a beautiful hybrid perpetual introduced by the exhibitor a few years since. Mr. Rumsey also exhibited several hundred cut blooms all more or less good, Niphetos and Maréchal Niel being especially good.

Mr. George Mount, Canterbury, exhibited a superb collection of cut blooms, a considerable proportion of which were staged with long stems, and presented a highly attractive appearance. The varieties represented in the collection included Mrs. W. J. Grant, Mrs. John Laing, Caroline Testout, Niphetos, Marie Van Houtte, General Jacqueminot, La France, Ulrich Brunner, Catherine Mermet (represented by some dozens of superbly developed blooms), Fisher Holmes, Baroness Rothschild, and Mrs. Sharman Crawford.

Caladiums.

For gorgeous colouring, bold leafage, and excellent cultivation the groups of caladiums arranged were scarcely to be surpassed. Messrs. J. Veitch and Sons, Chelsea, were to the front with a very fine group of large size. The specimens were marvels of high culture, both as regards size, colour, and general development. The shades of cream, green, crimson, scarlet, golden green, and rose were wonderful for their effectiveness and delicacy, and for the manner in which they harmonise when the varieties are associated; this was a very rich bank of colour. The varieties were all of the best, and at the back was a huge example of Madame John Box, and though it excelled all others in size, it was not better grown than the dwarf Mikado, or yellow and rose Princess of Teck; Prince Adolphe de Rothschild, Louis Van Houtte, Williamsi, a wonderful combination of scarlet, rose, and cream; Rose Laing, Madame E. Pynaert, crimson; Martha Laforge, creamy green; Duchesse de Mortemart, transparent white and dull green; Princess Royal, small foliage, golden green and rose: John Luther, crimson scarlet; Sir Julian Goldsmid, light green, shaded and veined scarlet; and Cascapava, creamy, with intense crimson-scarlet veins, were among the most attractive varieties. None of the plants were crowded, but it was possible to see the full extent of each specimen over the groundwork of maidenhair fern.

Messrs. J. Peed and Sons, Roupell Park Nurseries, Norwood, S.E., put up a grand lot of caladiums, arranging the specimens over a groundwork of maidenhair fern. There were superb specimens of Excellent, of which we give an illustration, Princess Royal, Candidum, Icaris, bronze and scarlet; Henry Dixon, creamy, with transparent spots; John Peed, Sir W. Broadbent, scarlet veins over a light green ground; Mrs. J. Peed, Princess of Teck, Ibis Rose, Golden Queen, Reine de Denmark, the beautiful Raymond Lemoinier, W. E. Gladstone, crimson, new; and Charlotte Hoffman, creamy, new, were among the most attractive varieties in a splendid group; the two latter are varieties raised at Norwood. Caladium argyrites and C. minus erubescens made an agreeable edging to the whole. Messrs. J. Laing and Sons, Forest Hill, were also extensive exhibitors of caladiums, putting up a handsome group, in which the forward and smaller plants were somewhat crowded. The plants were splendidly grown and the colours well brought out; the brilliant rosy-crimson and green variety, John Laing, occupied a central position, while large specimens of Triomphe de Comte, Altaire, Flammant Rose, and Baroo de Mamore were arranged along the back in front of the graceful palms. In the foreground were beautiful plants of Guaratuguator, rich crimson, new; Raymond Lemoinier; Sir Julian Goldsmid, Madame Imbert Koechlin, Rose Laing, Lillie Burke, Miracema, transparent pink; Ladas, rosy-scarlet; Mons. Comte, whitish, with scarlet veins; the two popular dwarf caladiums formed an edging together with panicum.

Clematis.

Messrs. Richard Smith and Co., Worcester, once again brought their superbly grown clematis, arranged as usual on balloon trellises, and covered with huge flowers of great substance and beauty. About two dozen of these large specimens, each measuring about four feet high by two and a half to three and a half feet through. Mrs. George Jackman is the best white; Princess of Wales is pale blue; Marie Lefebvre, paler blue, with dark centres to the segments; Madame Edouard Andre, deep rosy-crimson; Countess of Lovelace, double blue; Enchantress, double white; La France, bright purplish-blue; Purpurea elegans, deep purple; and Lawsoniana, lavender were all superb varieties well worth cultivating.

A charming group of clematis came from Messrs. G. Jackson and Son, Woking. This exhibit was very fresh and interesting, as all the varieties were coccinea hybrids; most of the specimens were arranged on balloon trellises, but several were trained as pillars, and some over rustic arches. In every case the flowers are tubular, and a selection of varieties would include Countess of Onslow, bright rosy-red; Duchess of York, blush white; Duchess of Albany, silvery-rose; Grace Darling, rich rose, a more starry form than most; Sir Trevor Lawrence, deep crimson, the newest form; and Admiration, pink, with the segments margined with purplish-rose. A few spiræas and some ferns gave this group a most cool appearance.

Hardy Trees and Shrubs.

A most brilliant effect was produced with hardy-flowering plants by Messrs. J. Veitch and Sons, Chelsea, who had a large display in the big marquee. Some choice rhododendrons made up the centre, a light form named Sappho being very prominent flanked by Lord Eversley, deep rose, and Prometheus, a rich red form;

A MORNING MIXTURE.

Diluculo surgere saluberrimum est.

I AM going to deliberately devote a paragraph to that hoary and time-worn topic—the weather. And why I am going to do it is this: Whenever in the past I have made an incidental reference to it, whatever its nature during the week or two that elapses between the mixing and sending out of the morning dose, a change has contrived to take place, so that the reference is invariably inappropriate. Well, I want a change to take place now, and I give the clerk of the weather a chance of confounding me by basing my remarks on an assumption that it is pouring with rain everywhere. If he trips me up, I shall have made one more sacrifice on the altar of my Queen, my country, and my neighbours' seed beds, which (the seed beds) are at present in a genial condition of paste.

Successful gardening is not the science which some people would endeavour to make out: it is the science of taking opportunities. A man who has got into the habit of promptly seizing chances is a man who could become a good gardener, whether he be at present a Cabinet Minister, a Yankee admiral, or a professional window cleaner. But, inversely, the man calling himself a gardener, who has not mastered the simple art indicated, is as little likely to be a successful horticulturalist as he would be to become famous at the India Office, or in charge of the Cuban squadron. Disguise it how you will, there are no terrific secrets in gardening, but there are certain elements making for success, and the nearer you get to them the better good work goes on. There is usually a specimen of the genus hobbledehoy in my garden, and during the last twenty years a fair string of them (they are known to local horticultural wits as Peter's pigeons, I believe) has passed through. All these young men have one lesson impressed upon them—never to let a chance slip. If the conditions for sowing a successional row of peas are favourable to-day, then to-day, and at no other time, has that row of peas to be sown.

I tolerate, sometimes with amusement and sometimes with respect, those venerable maxims which we are being solemnly assured at our lectures and in our papers are vital to horticultural progress. We all know those maxims. One of them is, never water in dribblets. I have shown up the absurdity of this from a practical point of view before, and now class it as amongst the simply laughable. Another is, keep light soil close, so as to conserve the moisture; it is docketted with the dribblets. A third is, keep the hoe moving in dry weather. Excellent! I am a thorough believer in it, though it is a little humorous to perceive that some of our estimable advisers have got so much into the way of quoting it that that they do so as cheerfully now we haven't any dry weather as when the ground is parched. But whatever the maxim be—whether it be one of those which we keep on using because everybody else does, or one of the list that common sense and experience teach us the value of—I am prepared to back in practical importance the one named above—seize your chances.

The early morning's walk through the garden shows many things in which we can later in the day take occasion by the hand. There is evidence coming in from every quarter about the prospects of a good fruit year. Every man who has his garden has the evidence before his eyes. There has been abundant blossoming, and pictures of beauty the trees have been; but we want more than present beauty, and that is just what many will not get. Old trees, neglected middle-aged trees, even young trees, there are in abundance, which are utterly incapable of swelling off their crop in perfection. They will begin to swell it, and they will succeed to a certain point, but then their energies will fail them, and fruit which ought to have grown to noble proportions will be small, wrinkled, pitted, and fungus-stricken. In the heavy masses of spurs at the present time an experienced eye will have no difficulty in detecting, first, the fruits which Nature will throw off in her own good time; second, the fruits which she may not get rid of, but which under no conceivable circumstances can make good specimens: third, the really promising. I go into no elaborate disquisition on fruit thinning, I simply revert to my maxim—seize your chances.

In another direction, too, we may take off our hats to coy Occasion, and gallantly kiss the hem of her fluttering robe. The thoughtful man perceives that unless troublesome frosts and blighting winds lighten the trees by robbing the cultivator, they (the trees) have heavy work before them. Now, it is at all times more difficult to find jobs for the hands on a wet day than a dry one, but there is one task which is pre-eminently a wet day operation, and that is the application of liquid manure. It sounds incredible, but over and over again I have seen the man who is loudest in his reiteration of the washed-out phrase "never give dribblets," choosing a period when the sun is fiercely hot, and the ground frantically dry, to apply his sewage. If this good man were to indulge in a little less reiteration and a great deal more thinking, he would learn to handle both the dribblets and the sewage better. My present theme is the latter, and I say with regard to it—take advantage of the present wetness of the soil and put it on. If the reader tells me that he cannot do so, for the same reason that a writer could not say anything about Lapland snakes, then I beg respectfully to invite him to imitate my own proceedings, which are—to put a pound of superphosphate and half a pound of guano (not the other way about, if you please) into a ten-gallon tub of water, to stir well, and to apply through a can at the rate of a gallon and a half to the square yard.

When the aforesaid thoughtful cultivator is looking over his fruit spurs he is quite likely to observe some curling of the leaves, and if he opens them out he is pretty certain to find within a creamy caterpillar, about half an inch long. A dreadful nuisance is this caterpillar, especially if you get a lot of him. I cannot truthfully say that getting rid of him is a wet weather job. Try it, and you will find the reverse. But there is one consolation, like the majority of grubs and caterpillars, including that vicious pest the onion fly, continued heavy rain tends to keep him down. Should the clerk of the weather trip me up by ordaining a dry spell about the time these notes appear, the caterpillar must be attacked. No! I am not so sure that it will be Paris green. I am beginning to fight shy of that appetising dish. If I could always be sure of getting an even quality, and if I could be equally certain that the sprayist faithfully carried out his instructions by keeping it rigorously mixed, I should look no farther. But the various editions of Peter's pigeons rather prefer to leave the mixture to its own devices, so that part of it does no harm whatever to the caterpillars, and the other part scorches the tree, for the reason that the particles settle down. I am therefore falling back on my stock emulsion of soft soap and paraffin. It does not poison the caterpillar like Paris green, but it worries and thins him in its own convincing way.

I see a writer refers to what he calls a long-standing delusion amongst gardeners that peach blister is caused by cold winds in spring, and proceeds to demolish the "delusion" by describing the real enemy in all its dread latinity. I was not aware that gardeners in general did labour under the delusion. I thought it was a generally understood thing that the wind stopped short at predisposition, and that the culmination rested with a fungus. This question was thrashed out many years ago in a horticultural journal. I don't remember quite how long it is since, perhaps twenty years, but both our Editor and myself were not the "stout parties" then that we are now. Both warriors—for there were two of them—were doughty champions, and the fight was a rare one. But although it is perfectly true that the wind does not do everything, it is the real culprit after all. The wind pinches the tender young foliage, and down comes the fungus.

LICUALA JEANENCEYI F.C.C. TEMPLE SHOW.

I have had a good illustration of the course of events just lately. A jutting end of one of the lean-to catches the sharp end of the nor'-easters just at that particular point where our present "pigeon" thought it expedient to open a ventilator; why, no one knows, certainly not himself. In an area corresponding to a nicety with the flow of the current, we have blister, and a bad attack too. Of course, being there it would spread, wind or no wind, if we let it, but within an hour of the mischief being observed the wretched *locum tenens* of the absent chief had had his wigging, and been started on a brew of liver of sulphur, a quarter of a pound to ten gallons of water.

I have just been reading "Memories of Ghent," by Servator. So Peter did go there after all, and what is more, took his inch of lead pencil with him!

LUX.

THE BEST GUIDE to the garden for the whole year is the "Gardening Year Book," containing practical articles on the cultivation of Flowers, Fruit, Vegetables, &c. Price 1s. "Gardeners' Magazine" Office, 4, Ave Maria Lane, London.—[ADVT.]

MELONS IN POTS.

THE culture of melons is frequently ably treated on in the pages of the GARDENERS' MAGAZINE in its calendar notes, but as it is impossible to go into details in the same, a brief note on pot culture may not be out of place. Many have failures with melons owing to the rich root-run afforded, or to which the roots gain access. One may, however, with advantage employ pots, and thus curb the roots, and by so doing induce early fruiting, and prevent gross leafage. In the first place, those who need early melons will find pot culture the best, as here earliness is ensured, and though it is not well to overload the plants, there is no difficutly in taking three nice-sized fruits, and even four, from a plant in a large pot. There is another mode of culture well worth noting, and this is what may be termed the cordon-system. This consists of growing in smaller pots, 10 inches being ample. The pots are plunged to the rims; this allows of liberal top-dressing after the fruits are set, and the perfecting of fine fruits. By cordons it will be understood a single growth is secured, and the plants are from fifteen to eighteen inches apart in the bed at the time the pots are plunged; this may appear close, but it should be remembered that with cordon growth there is close stopping and the melon does remarkably well under this system. Naturally only a limited number of fruits must be taken; from a large variety two fruits are ample, three from a medium, and four from a small sort. On the other hand, if earliness is the cardinal point, I should not hesitate to allow one or two fruits on a plant here and there, as it is important to obtain the first set so as to give all the plants the same treatment, for with fruits at different sizes or ages there is a difficulty in finishing them.

With melons grown in houses the plant is allowed to run to three or four feet and then stopped, and the fruits secured at the earliest period possible. Of course, shoots not needed for fruiting are stopped closer. By this mode of culture the roof space is quickly covered, and fruits are obtained in a shorter space of time than if the plants are allowed to make more growth. More than the requisite number of fruits are set, so as to be on the safe side, and only the best retained. There must be strict attention to stopping, as if the growths run wild there is an end of the cordon system, and the plants fail. With fruiting shoots a little licence may be allowed, but I stop at the second joint beyond the fruits at the start, and allow more joints for future stoppings, as it is an easy matter to tie up the growths so that they do not interfere with the other plants in bearing. For small houses this mode of culture is advised, as it soon furnishes fruit, and, if desired, many varieties may be tried. On the latter point, it is doubtful advice to recommend mere variety, and I do not do so save merely for the sake of trial.

There are other advantages in this system, for gross growers fruit more freely, there is less anxiety as to setting, and the crop is obtained in less time and with less fear of canker than usual. When in pots the plants can be treated better as regards foods; a much firmer, shorter growth is thus secured, and early fruiting induced. The crop, though smaller probably than on plants with more freedom, is more reliable.

I have dwelt at greater length on cordon culture than I intended, but the system is not unlike that for melons in larger pots. Large pots may be employed; many use inverted seakale pots, and this allows of rooting through into the soil, but this matters little so long as the pots are sunk and liberal top-dressings given. I rely more upon the latter than deep root action. For very early fruiting I find sixteen-inch pots large enough; indeed I have frequently used twelve-inch pots with advantage; much depends upon variety and feeding. For pot culture one may use a richer soil than is often advised for melons as growth must be quick, and several crops may easily be taken in the same house by having sets of plants to follow each other. With early fruiters much better results are secured by the use of bottom heat, and, of course, if the pots are too near the hot-water pipes there will be few bottom roots, and in this case there will be more need to encourage surface roots. We feed our plants freely; the pots are not quite filled at planting, and new soil is given as growth is made, but near the stems care is needed to place porous materials. This method is for early fruits, but for later crops larger pots filled at planting time are adopted, and a liberal top-dressing of bonemeal and loam given later.

I am not in favour of starving melons by the use of poor soil; it is far better to obtain early setting and sturdy growth by giving less root-run. In frames or beds of manure here we always plunge large pots, and fill these with the rooting materials in preference to the chance work of having to wait a much longer time for the fruit, for restricted root-action is conducive to early setting. So far I have never seen evil result by a free use of good soil, provided it is given so that the fruits have the benefit of it, and this, I think, will be best insured by liberal top-dressing; there are other means, such as liquid manures, once the fruits are set, but the evil to be avoided is feeding before it is needed, as there should be enough food in the soil, even in pots, to build up plants large enough to produce abundance of flowers. There are a few difficulties with melons in pots, one being that more moisture is needed at the season the fruits are swelling than is usually given; more foods are also necessary, but there is a gain in the end, as one can feed at the right moment and omit moisture when the fruits are maturing, thus securing better flavour.

Syon House Gardens. G. WYTHES.

Hardiness of Tea Rose Safrano.—We were able to cut some very nice blooms of the above rose both from the open and against a very much exposed east wall, on January 4 of this year, which says a great deal for the hardiness of the variety, as we registered 9 degrees of frost during December, and there were plenty of buds to open on January 4. It would be very interesting if some of your correspondents would give their experience of the amount of frost rose buds can withstand and open satisfactorily afterwards. Several of the hybrid perpetuals gave us blooms in January, so also did Gloire de Dijon and Homere from the open garden.—R. TURNBULL, *Beachley, Chepstow.*

POTTING CHRYSANTHEMUMS.

A VERY important stage in the year's work amongst chrysanthemums is reached when the plants are sufficiently advanced to require their last potting. Generally speaking, this final potting time is during the last week in May, but there may be, and in most collections doubtless usually are, a number of plants which will require potting a few days earlier or later just according to their condition. No fixed date need be given, the time for the work to be done is always governed by the weather and the state of the plants themselves. It is most unwise to leave plants in small pots when they really need shifting into larger ones; and on the other hand, it is equally bad practice to give more root room before the six-inch pots are thoroughly well occupied with roots. As it is almost impossible to have the whole batch of plants ready for potting at one time, even supposing it were desirable to do so, there is a week or two occupied, more or less, in putting the plants into their flowering pots. The labour involved in this final potting and subsequent arrangement in their summer quarters, is perhaps the heaviest item in the whole season's work, and though it must not be regarded as the *summum bonum*, any more than any other detail may, it certainly contributes largely to ultimate success. There are many details in connection with the work on which advice will bear repetition to those interested, and to none more than to those who take up the cultivation of chrysanthemums as a recreation for their spare time.

One needs ever to be looking ahead, and to make due preparation before the work requires to be done. Soils, manure, pots, stakes, &c., should be to hand early in the month, so that no unnecessary delay is caused for want of these at the proper time. The loam for this shift must be the best procurable, containing plenty of grass-root fibres, and should have been dug a few months previous to using. Chop or pull the turves into pieces as small as chicken's eggs, and in like proportions, the following quantities will compose an excellent potting soil: Three parts loam, half part each leafsoil, decayed horse manure, old mortar rubble, and ashes from garden refuse fires, with a sprinkling of finely ground bones. Of this latter use more or less according to the quality of the loam. It is a mistake to add a large quantity of artificial manures, as this only renders the soil unhealthy for the new roots, and is much better given at a later period. The manure from old mushroom beds is first-rate for lightening heavy soils, and may be used a little more freely than that which is less decomposed. The bone meal should be of best quality, and a few half-inch bones may be sprinkled over the drainage for all the strong growing varieties. Soot we do not use in the soil, but later in the season it is given freely in the water.

For the greater number we prefer ten-inch pots, but for late-struck plants, and for those naturally not over robust, smaller sizes are best, as it is worse to give too large a pot which does not become well occupied with roots than one too small. Mutual Friend, Australie, Baron Tait, Lady Byron, Therésè Rey, Reine d'Angleterre, and others not more strong growing, do best in nine-inch size, whilst Hairy Wonder, and such moderate growers, will do well in a slightly less pot. Any varieties, too, which are especially liable to damping of the blooms, must not have the largest size pot; over strong growth must not be encouraged, as it predisposes the plants to this weakness, Drainage must be carefully and systematically laid in the pots, as a free outlet for the quantities of water which chrysanthemums need is most important; a light dusting of soot may be sprinkled over the drainage to prevent worms readily finding their way into the soil. The bones used either in the soil or over the drainage must not be raw ones, as these are very apt to cause an unwholesome condition of the soil, into which the roots will not readily penetrate. Frequently mistakes of this kind have been made, especially in putting too many amongst the drainage, where their decomposition has been the cause of a serious injury to the roots. Dissolved bones are the best. Before potting be sure the plants are in a moist condition, though we do not like repotting a plant immediately it has been watered. Place some of the most fibrous soil over the drainage to prevent the fine mould washing down into it, and take care that the new soil is neither dry nor wet, as either condition is not suitable for good potting. Place the plant so that half an inch of soil may cover the surface of the ball, and do not fill the pots too full; about an inch and a half space should be left for watering and subsequent topdressing. Pot evenly and firmly throughout, so that water will soak regularly through. No water need be given for a few days after potting, but if the weather is bright and dry frequent syringings will do much to help the plants recover the check of repotting. They may stand close together for a week, and then, about the middle of June, be arranged in their summer position.

I have not seen any further traces of the leaf rust, and though I would urge all cultivators to keep a sharp look out for this, and to burn any traces they may find, I do not anticipate much trouble in dealing with the fungus causing the disease. Supposing the variety which infests carnations to be the same as that on chrysanthemums, I may point out that the probabilities are that the spores remain fertile for some months, because on an imported carnation plant we found spots last autumn, and these were carefully removed, and the plant constantly watched ever since. No new fungus marks developed until recently, when we have found a little spot or two.

W. H. LE[illegible]

Trent Park Gardens.

A RACE FOR LIFE is taking place in our midst every day, and too often, alas, the [illegible] ends in death. People, as a rule, are apt to look upon some slight ailment which may [illegible] them with contempt, and they thus ignore the simple remedies which would speedily [illegible] to health. When too late they see their error, and bitterly bewail the folly which brings [illegible] premature grave. Holloway's Pills, if taken in regular doses according to directions, [illegible] purify the blood. Disease is thus prevented from weakening the system, and the [illegible] sound constitution is enjoyed. At this season, when fevers, dysentery, and stomach [illegible] common, this wonderful medicine is specially useful.—[ADVT.]

VEGETABLES FOR EXHIBITION.

SEAKALE.

SEAKALE (*Crambe maritima*) forms one of the most important crops cultivated in the kitchen garden, and it is to be regretted that this vegetable is not more widely grown among amateurs and cottagers. Unquestionably, well blanched it is most delicious, and liked by nearly everyone when properly cooked. It is not at all fastidious as to soil, as almost any kind will grow it to perfection. Perhaps the blanching process is the most troublesome, but this little difficulty is easily overcome. Seakale is also easily propagated either by root cuttings or seed, but I much prefer the first-named system, and, after a start has once been properly and systematically made, very little trouble will be found in increasing or maintaining a constant supply. In forming a permanent bed—that is, a place where seakale is intended to remain and be forced annually—an open, sunny position should be chosen; in fact, this will apply to all modes of cultivation. The ground should be heavily manured (farmyard manure being preferable), and well trenched to the depth of from two feet six inches to three feet during autumn, but the planting should be deferred till early in March. The ground should be well forked over, and the rows staked out; plenty of room should always be allowed both between the rows and from plant to plant. I advise a distance of four feet between the rows, and two feet six inches between the plants, as this will allow space for working, and also for the sun and air to assist in the building and ripening up the crowns—an important point towards success. One-year-old crowns should be planted in threes, triangular fashion, about six inches apart. The crowns should be just buried, after which some finely sifted cinder ashes should be placed over and about them. This is a good preventive of the ravages of slugs, which in some seasons are a great annoyance and do much mischief. These crowns should not be forced the first season, but allowed to grow at their own sweet will. The flower head, which will be sure to appear, should be cut out before the flowers open, while the crops must be hoed and kept free from weeds. In autumn, as soon as the leaves have died away, forcing may be commenced, generally speaking, about the first or second week in November. Carefully remove all rubbish and any of the decayed leaves, point over the ground, and build up cones of ashes over the crowns. Seakale pots should be placed over these and covered with some sweet fermenting material, good leaves being far preferable to any other. Use only just sufficient to create a gentle heat, as an excess is very detrimental to the flavour of the produce when cooked; a safe temperature is from 50 to 55 degrees at all times. Air must be quite excluded, and for later supplies as the season advances, less material will be required, and for the very latest cuttings simply cover up the crowns with a good depth of ashes, and over this build some soil, ridge shape, which should be well patted with the spade. The cracking of the soil denotes when the seakale is fit for cutting, and some of the very finest and best flavoured seakale is produced in this way. As soon as the crop is cut the leaves and pots should be removed, once more covering the roots with ashes; the ground should be then forked over and left neat and tidy for the summer. It is surprising what a length of time a plantation will last in this way, in fact, if properly attended to, it is something like wine—age improves it. This is the old method of forcing seakale, and, I think, without a doubt, still the best when quality and flavour are considered. But in these go-ahead times it is not fast enough for many, and especially for market gardeners.

CALADIUM EXCELLENT, TEMPLE SHOW.

When large quantities are required, a more rapid mode of production must be employed, and annual plantations made. This is most easily accomplished. In lifting the crowns for forcing, all the small roots should be trimmed off with the knife, cut in lengths of six inches, and tied in bundles of twenty-five; any time during the winter months will suffice for this work. The bundles should be stood on end thickly together in boxes, placing a little fine soil about them. They may be placed under the greenhouse stage, or even in cold frames, when they will quickly form eyes. Early in April they should be planted out on well prepared ground, in the same way as previously advised, at a distance of eighteen inches between the rows and one foot from set to set. Plant with a dibber, placing a few ashes over each crown, and should the weather be dry, give a thorough watering in. Several shoots will generally break away, and after these have made a fair start, they should be reduced to one, of course leaving the strongest. Frequent hoeings during spring and summer will be necessary, and in dry seasons the crop will be much improved by frequent drenchings of farmyard liquid manure, well diluted. Good forcing crowns are produced annually by hundreds of thousands by this mode of culture. As soon as the foliage has died away in the autumn, the roots may be lifted and forcing commenced. In many large establishments seakale is in request every day during winter, and when plenty of ground and labour are at command, little difficulty will be experienced in producing it. I know of no better place for bringing this forward than the mushroom house, providing the light and cold air are excluded, but if a suitable temperature can be found, it may be forced almost anywhere.

Seakale is easily raised from seed, but, as before stated, I much prefer root cuttings. Nevertheless, some may think differently. The ground should be prepared in the same way as advised, and the seed sown the first week in April in drills about one inch and a half in depth. The seeds should be put in regularly six inches apart, removing every other seedling when large enough, thus finally leaving them one foot asunder and eighteen inches from row to row. They require two seasons' growth before fit for forcing.

From the middle of November till the end of April seakale forms an important and telling dish, but it must be presented in the very best possible condition or little notice will be taken of it by expert judges. It should be thoroughly blanched, stout, not showing the flower heads, and from nine to ten inches long. Twelve heads will make a good dish, and it should be stood in an upright position on a carpet of parsley. It should not be cut till the last moment, and then the air must be kept from it as much as possible; do not expose it on the exhibition table before necessary. I am only acquainted with two kinds of seakale, the old one which has purple tips when forced, and the newer sort, named Lily White, which, to my mind, is an improvement both in appearance and quality, though not so hardy as the older form.

Aldenham House Gardens. E. BECKETT.

THE WATER GARDEN.

Plants for the Waterside.

FOR bold effects by the waterside, perhaps nothing can compare with Gunnera manicata, of which plants twenty-five feet in diameter, with leaves over nine feet across, may not unfrequently be seen in Cornwall and other counties. Gunnera scabra, though not so large, is also most effective. The tall Arundo donax requires a similar position; that is to say, one where its roots can find abundance of moisture, and where the situation is sheltered against rough winds. Bamboos can hardly be considered here, although they do not object to be within easy distance of water. They would certainly make a fine background at some distance from the waterside proper, and the same might be said of Polygonum Sieboldi and P. cuspidatum, which are bold and handsome, but have a habit of becoming wild and so smothering better things. Rheum palmatum and other rhubarbs like the Siberian Rheum undulatum, or the Himalayan Rheum Emodi, are also most effective, and the same may be said of Gynerium argenteum, Arundo conspicua, Elymus glaucophyllus and other ornamental grasses or large ferns like Osmunda regalis.

For groups of colour the following bold flowering plants may be recommended as being easy to grow, and flourishing remarkably well where their roots can feel the moisture. Lythrum Salicaria var roseum superbum, with long spikes of bright rosy purple flowers; Inula helenium and Telekia speciossissima, both having large yellow flowers and bold leaves; Senecio japonicus also has large yellow flowers four inches across on a stem four feet high, and leaves beautifully cut and deeply lobed. It grows well in a swamp, but refuses to grow in a dry position. The blue Himalayan poppy (*Meconopsis Wallichi*) and the yellow Gentiana lutea are both bold and most effective plants for a shady position by the waterside; while spiræas, like the huge Spiræa gigantea, S. venusta, S. lobata, or the handsome chelones, such as Chelone barbata, C. glabra, and C. Lyoni will succeed in either shady or sunny positions. Lilium pardalinum and Lilium giganteum may also be mentioned as effective tall flowers for the waterside.

Medium-sized Plants.

Under this head I will deal with plants varying from one to three feet in height that are suitable for natural or artificial swamps or bogbeds, or the water-soaked banks of ponds and streamlets. The plants here mentioned are equally suitable for the banks of open water or for ponds and streams connected with a rock garden, the only difference in arrangement being that in the case of water-gardens on a large scale the individual groups of plants should be larger.

In a sunny position few things can rival the iris. Both the Iris germanica, with its hundreds of variations, and the handsome Japanese Iris Kæmpferi love the waterside. But in planting them it is of no use to put in a plant here and there; to be seen at their best they should be planted in large irregular colonies, just as we would find our native yellow iris. The same might be said of the spiræas; S. palmata, with its large feathery plumes of pink flowers, is a handsome plant, but it is infinitely more effective when massed than when isolated. Spiræa palmata alba, with white flowers, S. astilboides, S. japonica, or even the double meadow sweet S. filipendula fl. pl., or its near relative Astilbe rivularis, also should be arranged in groups. The double marsh marigold (*Caltha palustris fl. pl.*) becomes a bold and handsome plant when its roots can find abundant moisture, and not less attractive are the white flowering Caltha leptosepala, from California, and Caltha purpurescens, the latter having orange flowers and purplish stems. Another class of flower which grow more vigorous near the waterside than elsewhere are the handsome Globe Flowers, or Trollius, of which Trollius europæus, T. napellifolius, and caucasicus are yellow, while T. asiaticus has an orange shade, and T. europæus albidus is creamy white. The day-lilies, or hemerocallis, succeed best in light soil some little distance away from the wettest ground, but they have a decided love for a fair amount of moisture. Hemerocallis Thunbergi, H. flava, H. fulva, H. distycha, and H. japonica are among the best; all have yellow or orange coloured flowers.

The well-known Funkia Sieboldi and the pure white sweet-scented F. grandiflora alba develop into noble specimens in the proximity of water, and are almost as effective with their bold leaves as with their handsome flowers. The last named is more tender than the former, and requires a little shelter. In Cornwall and South Devon it forms magnificent clumps, requiring no protection there. Myosotidium nobile, which belongs to the order Boragineæ, and resembles a huge forget-me-not in its lovely blue flowers, and a funkia in its large leaves, comes from the Chatham Islands, and is one of the rare plants seldom seen doing well. It is described as loving a shady position, but having repeatedly planted it in the shade with little success, and having since seen magnificently developed specimens in the full sun both at Enys and in the gardens of Mr. Poveys Rogers, at Burncoose, near Redruth, I am inclined to think that light soil, warmth and moisture are more essential to its well-being than shade. The different American cowslips or dodecatheons, also succeed remarkably well in a moist and sunny position, and will sometimes develop flower spikes nearly two feet in length. Perhaps the strongest and most robust is Dodecatheon Jeffreyanum, but D. splendidum, D. Meadia, D. M. album, and D. integrifolium, though smaller, are nevertheless most attractive and suitable for either the bog or the margin of water. Helonias bullata is perhaps more curious than pretty; it grows twelve to eighteen inches high, and has an oval spike of small purplish-rose flowers. The leaves are oblong lanceolate. This requires partial shade. There are quite a large number of rushes, grasses, or their allies which might form an excellent fringe by the waterside; of these I will only mention Carex pendula, Carex riparia variegata, Cyperus longus, Juncus effusus spiralis, and Scirpus Tabernæmontani zebrinus (*syn. Juncus zebrinus*) as being among the most suitable.

Exeter.

F. W. MEYER.

TAMWORTH PANSY AND VIOLA SHOW.

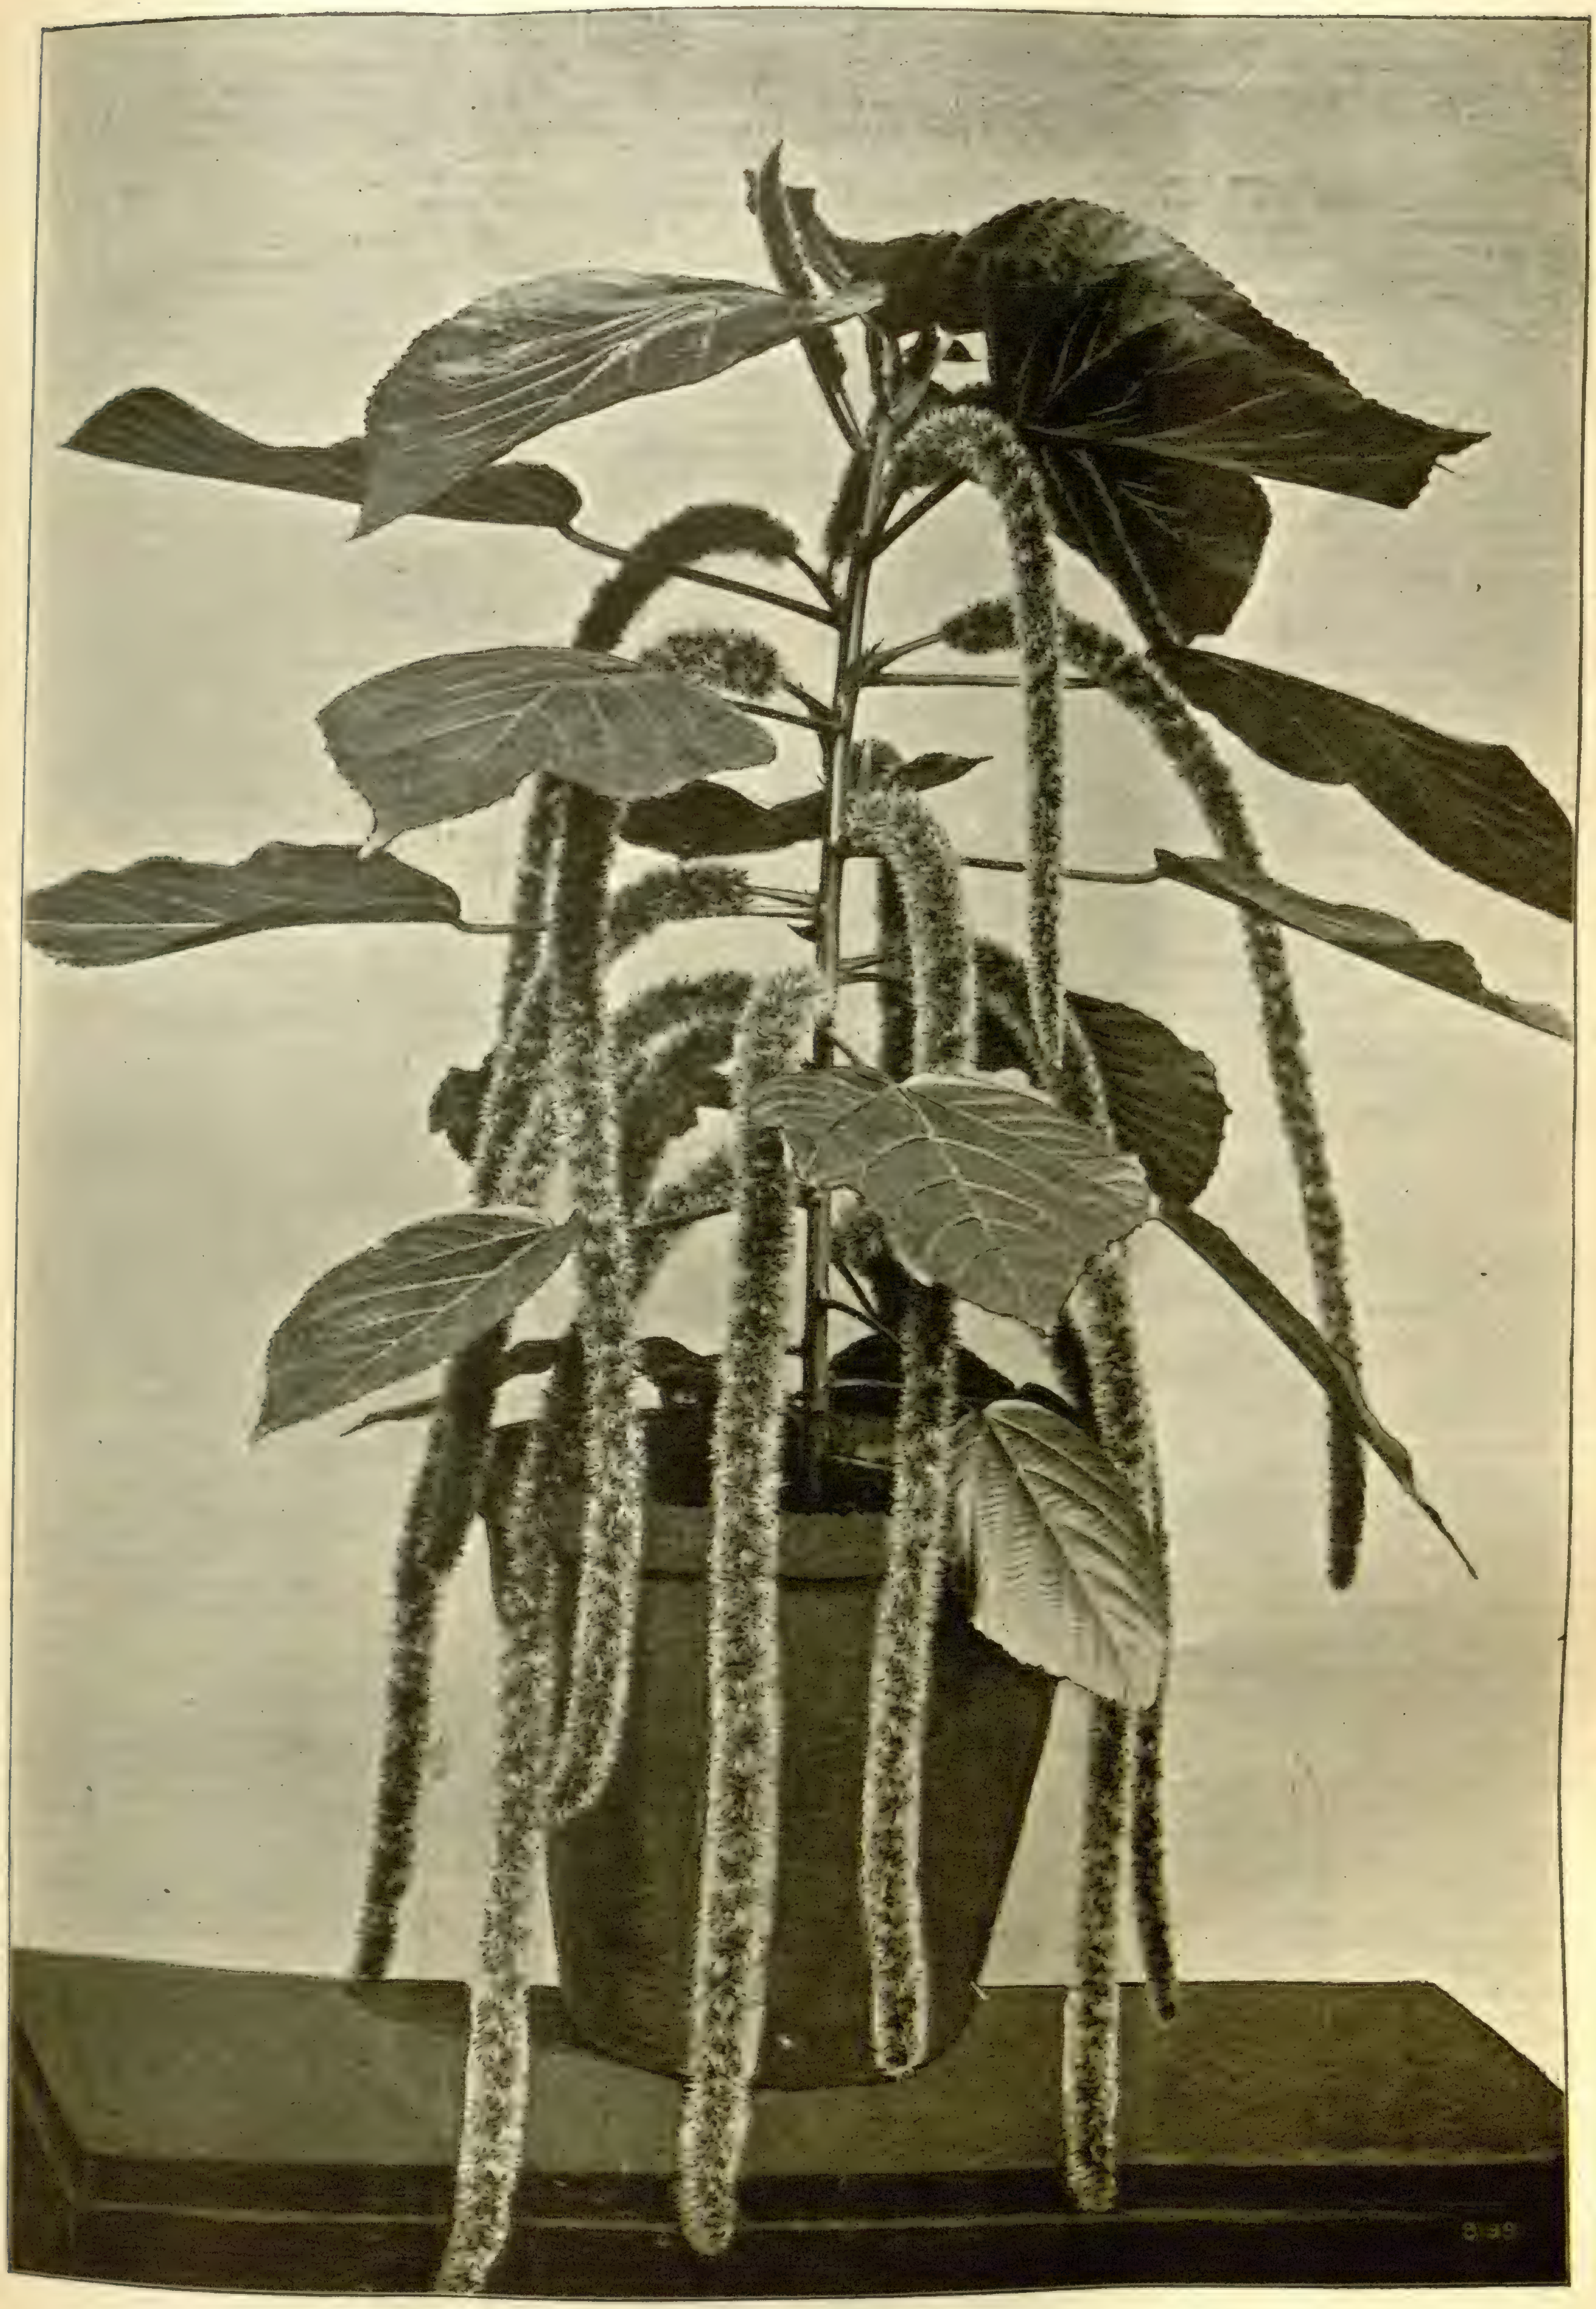
THE exhibition of pansies and violas originated and continued by Mr. William Sydenham, of Bolehall Grounds, Tamworth, was held in the garden of the gentleman on Saturday last. Considering the weather experiences of late, and more particularly so that of a few days previous to the show, it is almost remarkable that so meritorious a display was produced. The exhibition would have been still better but for the fact that the inclement weather of late had in many instances damaged the flowers almost beyond recognition, and there is little doubt that the fortunate prize winners were those whose gardens were situated in favourable quarters. By far the larger display was made with the blooms of the viola, and although there are many ardent admirers of the fancy pansy in the midlands and the north, there is evidence that a keener interest is being taken in the many pleasing and interesting types of the viola.

There were altogether some forty classes in which entries were forthcoming, and one feature, and a particularly pleasing one, was the beautiful array of decorative exhibits. The centre and one side of the tent was devoted to table decorations, wreaths, and other designs, in order that the decorative value of the viola and pansy should be demonstrated. This was undoubtedly a most successful enterprise, as in each instance the rivalry was keen and the decorative effect of true artistic merit. These classess were exclusively confined to the use of pansy and viola blooms, together with their own foliage and with that of the fern of a varied character. For a table decoration the four exhibits were decidedly good and very pretty, the first prize falling to Mrs. Lovatt, Newport, Somerset, [illegible] with a sharp contrast of indigo blue flowers, and those of yellow and white. These were arranged with viola foliage and maidenhair fern, and made a light and elegant arrangement. Mr. D. B. Crane, Highgate, London, N., was an uncomfortably close second with a light and tasteful combination of rich yellow and creamy white flowers; a choice assortment of ferns gave a pretty finish. Mr. J. M. Johnston, Tamworth, was a good third, he using Selaginella K[illegible] chiefly with the blooms of the fancy pansy. The competition with a wreath was very good, the first prize being awarded to Miss. Johnston, Tamworth, with white, pink and pale blue violas arranged with great taste. The wreath was a most lovely exhibit, better in fact than we could imagine was possible with these flowers. Mr. Johnston was second with rich purple flowers with maidenhair fern and Caladium argyrites as a contrast. Mr. J. Smellie, Busby, near Glasgow, was a good third with a light arrangement of light blue on a white ground. The Lyre securing for Mr. Johnston first prize was good, with strings of yellow violas, and framework of fancy pansies. An exceedingly fine exhibit of a huge heart in the class for a decorative exhibit of any other design than those specified secured for Miss E. Sydenham, daughter of the host, the coveted position of first prize winner. This was a most elegant and artistic piece of work, a creamy-white viola on a lavender-blue base, making a very beautiful contrast. This was also put together in a light and easy manner. A hand-basket from Mr. Johnson, rather heavily arranged, was awarded second position, and a neat little cross was placed third. The latter came from Mr. Smellie.

In competition for the prizes for twelve varieties of rayless violas, six blooms in each spray, Mr. W. Maxwell, Glasgow, was first with Dorothy, A. J. Rowberry, Pembroke, Sylvia, Blue Gown, Sweet Lavender in good form. Mrs. Lovatt was a good first for six varieties of the same type of flower, Lucy Franklin, Border Witch, Dorothy, and Sweet Lavender being among her best. Mr. J. Maxwell, another Glasgow grower, was second, A. J. Rowberry and Dorothy being well represented. The brothers J. and M. Maxwell were first and second respectively for three spray rayless violas. For twelve varieties self-rayed violas, Mr. W. Maxwell was first with Lemon Queen, Lizzie Paul, Jenny, Archie Grant, Duchess of York, and Niphetos, in good form; Mrs. Lovatt being placed first for six varieties of the same form, having White Flag, [illegible] Niphetos, and Duchess of Sutherland in fairly good condition; closely followed by Mr. J. Maxwell. The brothers Maxwell also secured the two prizes for three varieties of the self-rayed flowers. For twelve varieties, six blooms each, of any forms or colour, Mr. J. Maxwell was again first, showing, amongst others, Duchess of York, Goldfinch, Duchess of Fife, Bluecloud, Lig Barron, and Lizzie Paul; second prize was well secured by Mr. Leonard Brown, The Cottage, Seven Arches, Brentwood, for blooms of which showed what southern growers can do, but which, like others, gave evidence of the heavy rains of late. Specially good in his stand were Stephen, White Empress, Pembroke. Mrs. C. F. Gordon, A. J.)Rowberry, and a pretty pale-tinted seedling. Mr. Johnston had a grand lot, but these were arranged with fine effect with maidenhair fern, which was understood to be contrary to the rule; an extra prize was, however, given. Six sprays of this type went first to Mr. W. Maxwell, who had some exceptionally good blooms of varieties already mentioned; Mr. Johnston following him very closely. The brothers Maxwell were awarded first and second prizes for three sprays, each staging splendid flowers. A variety named White Empress secured premier honours as the best rayed white, although this was also seen quite rayless in other stands. Blanche, a pretty white rayless variety, secured leading position as the best rayless white, this being followed by Niphetos, a variety rather whiter. Archie Grant, staged by the Messrs. Maxwell, was the selected rayed blue variety. Dorothy and Britannia, from the same source, being those selected as the best rayless blues. Some neat blooms of A. J. Rowberry were placed first as the best rayless yellow; second prize going to Pembroke, a good yellow of the same type. Mrs. Lovatt, with Stephen, easily won first prize for the rayed yellow; Lizzie Paul following in point of merit for second position. This was put up by Mr. M. Maxwell. Mrs. C. F. Gordon was selected as the best rayed variety of the fancy violas, and was well shown by Mr. W. Maxwell; Goldfinch, from Mr. J. Maxwell, taking second honours.

There were a capital lot of fancy pansies, but in no single instance were they named, an omission which should be remedied on a future occasion. The leading prize winners were Messrs. J. and M. Maxwell, who seemed quite in [illegible] their blooms being beautifully fresh and clean, and the colours well defined. In these classes the competition was very good, but there was no comparison in the display they made alongside the freer-growing violas in so many interesting forms and colours.

Mr. Robert Sydenham, Birmingham, had a nice lot of table decorations and designs in which the carnation was arranged in the pretty silvered rustic tubes and [illegible] Mr. William Sydenham staged a grand exhibit of violas in sprays, those most conspicuous being Councillor W. Waters, Mary Stuart, Stephen, Mrs. [illegible] Bellamy, The Mearns, Blanche, Sweet Lavender, Lucy Franklin, Lemon Queen and Lizzie Paul. A pretty little rock plant of miniature dimensions, and [illegible] Tom Thumb, received a first class certificate, the flowers being a rich yellow with dark pencillings. Numerous designs, such as Prince of Wales feathers V.R., &c., were effectively arranged with chaste and delicate violas, and [illegible] striking exhibit with the sprays already referred to.



ACALYPHA SANDERI, F.C.C. TEMPLE SHOW. (Flowers vinous crimson.)

Work for the Week.

COOL ORCHIDS.

The species of oncidium suitable for cool treatment are mostly well worth the attention of the orchid cultivator; the chief cause of failure with these plants is permitting the flower spikes to remain on the plants until all the flowers fade, a pardonable mistake, perhaps, but one that is fraught with danger. Oncidium Marshallianum, O. concolor, O. cucullatum, O. macranthum, and O. phalænopsis are making a nice show in the cool house at the present time, and when the large branching spikes of Oncidium Marshallianum have fully opened their flowers it is a wise plan to cut them off and place them in water, for if allowed to remain on the specimen for any length of time, they will naturally exhaust the plant. Oncidium cheirophorum, O. Forbesi, O. crispum, O. varicosum, and its fine variety Rogersi, with any others that are starting to grow, may now have new material afforded them; the usual peat and sphagnum compost cannot be beaten if placed over good drainage; O. crispum and O. Forbesi require a few degrees more warmth than the others, and may be usually afforded these at the warmest end of the odontoglossum house. A very pretty orchid now in flower in the cool house is Ada aurantiaca; this, with its beautiful orange coloured flowers is very effective when arranged with odontoglossums of the crispum section, as each shows the other off to considerable advantage. As the plants pass out of bloom they may be repotted in a compost of equal parts of peat and sphagnum moss. Pots of a suitable size should be used, allowing plenty of drainage, so that the plants may receive abundance of water during the summer months without the compost becoming sour. The Ada thrives well in company with Odontoglossum crispum during the summer months, but it requires a warmer temperature during winter, for, if kept too cool, the leaves turn a sickly tint, and the under surface becomes badly spotted. Less water will be needed during the winter months, but the soil should never be allowed to become thoroughly dry. Epidendrum vitellinum is another beautiful cool orchid in flower at the present time, and one that lasts a long time in perfection. The plants when in full growth enjoy copious supplies of water at the root until its growths are completed, but, during winter, should be kept rather dry, or the leaves spot badly.

No time should be lost in repotting any plants of Lycaste Skinneri and its variety alba that have finished flowering, as they are now starting to grow freely. Well-drained pots should be used, large enough for the development of two seasons' growth, using a compost of fibrous peat and loam in equal parts, and a little fresh sphagnum moss mixed with broken crocks and charcoal. Great care is necessary in the watering of these newly-potted plants, for, if over-dosed with water, the young growths are apt to rot off, and disease in the bulbs ensue; even when in full growth water should be carefully afforded them. The foliage of these lycastes is frequently attacked by red spider, which must be kept in check by an occasional sponging of the leaves with soft water, while slight sprayings overhead on bright days will help to keep these pests in check. Green and black fly and thrips sometimes put in an appearance, and an occasional fumigation will be necessary to keep them down. Disas may now be placed in a cold frame in a cool and shady spot. The plants should be well syringed night and morning, whenever the weather permits, and never be allowed to become dry at the roots. The airing of the frame should be carefully attended to until the plants become accustomed to their new abode, then, in warm, rainy weather, the lights may be entirely removed. Carefully examine the plants occasionally for red spider and aphis, which sometimes attacks them.—E. Shill, *New Hall Hey Gardens.*

STOVE PLANTS.

The gardenia is one of the most choice among stove-flowering plants, and where flowers are required in quantity the season through, the most successful method is to plant them out. In an old pocket book of mine I have noted the daily cutting from a row of gardenias planted out in a three feet wide border, the length of a forty feet house, at one establishment where I lived as journeyman. We commenced cutting on February 22, and finished November 14, the total being upwards of 3,000 blooms. As I never saw a more healthy hedge of gardenias, or larger individual flowers, the best thing I can do is to detail the treatment they received. The border was thoroughly drained, and as the house had formerly been a pine stove, there was plenty of bottom heat, the gardenias were given the front three feet of the bed. Over the drainage fibrous turves were laid, grass side down, and over this to a depth of eighteen inches was placed a compost of three parts rough fibrous loam, one part leaf-soil, and one part each of lime rubble and charcoal. The gardenias were planted two feet apart, and in two years, by means of stakes placed on either side, the row at two feet from the centre was trained to form a hedge four feet through, and no pruning was necessary after they had filled their allotted space, as all the flowers being cut with long stems prevented the plants reaching too great a height. Stimulants were afforded freely in the form of artificial fertilisers, liquid manure water, and soot water. Mealy bug was kept thoroughly under by syringing the plants every Friday evening with paraffin and soapy water. No shading was given even during the hottest weather, but air was freely admitted during the middle of hot days; three syringings were given daily, at six a.m., closing time (half-past two), and again at five p.m., while the duty man had to thoroughly damp the house at nine p.m. The flowers were cut every morning before breakfast, and placed in water in a cool fruit-room. In places where pot culture has to be relied upon, as the plants go out of flower, gradually harden them off until they will stand in a cold frame, giving very little water. After standing here two or three weeks cut them well back, and remove them to a warm house where a humid atmosphere is maintained, and where they will soon push into growth; any requiring it can then be repotted.

As plants of Clerodendron Balfouri come into flower, syringing must be discontinued; in fact, they would be better removed to the conservatory, and stood in a position free from cold draughts. Allamandas on balloon trellises, that are coming into flower, and have had their shoots trained up strings, should now be tied into position; to prevent the snapping of shoots during the operation allow the plant to become rather dry, as then the shoots will be found more pliable. Tabernæmontana coronaria fl. pl. is now flowering freely, and must be fed; it is a very free bloomer, with flowers sweetly scented, and so it is worthy of extended cultivation; cuttings of the young shoots are easily rooted in sandy soil by plunging the pots in the propagating case and maintaining a moist heat around them. Propagating cases should always be made in divisions, so that those cuttings requiring a drier atmosphere with more air can be kept separate from those requiring a close moist atmosphere. Plants of Hibiscus, that are coming into flower, will require abundance of water, with stimulants occasionally; greenfly is a great pest with these, and must be kept under by a free use of the syringe. As Fransisceas go out of flower, they should receive a slight pruning, and any repotting necessary may be done when growth commences again; these plants like plenty of water at the root, and a free use of the syringe overhead. The present is a good time to put in a batch of cuttings of Fittonia argyroneura and F. Pearcei, the plants to be retained in two and a-half and three-inch pots for dinner-table decoration during the late autumn, F. argyroneura is perhaps the best for this purpose, and when dotted over a table the cushions of silvery-veined leaves have a very nice effect.

Less fire heat will be necessary to keep up the requisite temperature now, especially if the houses are shut up early in the afternoon, so as to bottle up the sunheat. Examine the plants before closing the houses, to see that none are suffering from the want of water. A young man, whose heart is in his work, will know which among his charges are likely to require water more than once a day, and will give the necessary attention. Afford stimulants to Urceolinums until such time as the leaves begin to show signs of ripening, when feeding must be stopped, and less water given. Use the syringe freely on all bright days, keep the evaporating troughs filled, and damp walls and floors frequently during the day.—J. Tunnington, *Ripley Castle Gardens.*

KITCHEN GARDEN.

So far there has been no necessity to use the watering-pot to promote the growth of asparagus this season, for the welcome showers that visited us about the middle of the month thoroughly moistened the soil to a considerable depth, there having fallen in this neighbourhohd about one and a half inches in the course of a week. Asparagus has consequently been plentiful, but as such heavy crops somewhat exhaust the soil, it is well to give the beds a dressing of artificial manure, to be washed into the ground at once, before the plants become exhausted. It is far better to feed the plants now when in active growth than in the winter when dormant. Broad beans will now be in flower, and where there is the least signs of aphis, the plants should be stopped and the points carried away and destroyed. The fly can only subsist on the young growths; therefore, if these be removed there is no fear of injury. Owing to the recent heavy rains, the plants have grown somewhat taller than usual, and are on that account liable to be broken down by high winds; in such cases pinching should be done a little harder than usual, to enable the plants to retain their perpendicular position. Another sowing may be made for a late crop, and the situation chosen ought to be a moist one, as late sown beans, especially on light dry soils, are most difficult to grow in hot seasons. French and runner beans should also be sown for succession, choosing a sheltered situation for the latter, to prevent their being blown about by rough weather in the autumn. With the exception of the check that the early ones received toward the end of March and early in April, the season has been favourable to the growth of the pea crop, which as a rule looks well. Where there are signs of any blanks, through the plants not making the progress anticipated, make small sowing of an early kind to fill up the gaps. Pay special care to the staking of those already far enough advanced, and where the plants are too thick they should be thinned to allow the others more room. Successive sowings should be made of some good late varieties, such as Autocrat, Late Queen, and Michaelmas, any of which will be sure to give satisfaction.

The planting of such things as Brussels sprouts, cauliflower, borecole, and broccoli, will now be general, and should be pushed forward whenever the weather is favourable. Lettuce from the early sowings will now be in use; to maintain a constant supply of fine tender hearts, the plants must be put out when small, allowing ample room for them to develop. Tomato plants that have been brought forward under glass may now be planted out in warm situations, but in cold districts, and where the soil is heavy, it is seldom they pay for the trouble, as the frost cuts them down before the fruit is ripe. Where frames or pits that have been occupied with potatos or French beans can be utilised, these will be found useful for growing tomatos in, as the growths can be trained close to the glass, and in this way far more fruit can be gathered from a dozen plants than from the double number grown in the open, unless the weather should be exceptionally favourable to them. When planted on stiff soil, a quanity of light material should be worked in to keep it open, so that water may pass through freely; for too soppy a growth is not conducive to a free set of fruit. Capsicums and chilies may now be planted on a warm border or in a sheltered situation. The ground on which these are intended to be grown cannot be too rich, for the freer the growth the better the results. They should be planted in rows, and about a foot or fifteen inches apart each way. In cold districts it is better to grow them in pots and place them where protection can be afforded by means of spare lights, when the weather is unfavourable. Both chicory and dandelion may now be sown to produce roots for lifting in the winter. The former on good ground will require thinning to a distance of a foot apart in the rows, while nine inches should be allowed to the latter. Many herbs are required for winter use, therefore it is well to make special preparations at this time of the year. If the young shoots of mint be taken off and rooted in pans or boxes, they will be found far more serviceable than roots lifted from the open ground and potted up as wanted. It is a good plan to have the boxes six inches deep and about a foot wide, and of a convenient length to admit of being easily carried about. Cuttings root more freely in a cold frame where shade can be afforded them, after which they should be exposed to the full sunlight. Tarragon, thyme, and other herbs may be rooted in the same way. Make small sowings of radishes, mustard and cress, and chervil, to keep up a constant supply. The former will do better if sown on a north border.—H. C. Prinsep, *Buxted Park Gardens.*

FRUITS UNDER GLASS.

Early peaches will now be ripe, and require careful attention as to gathering if they are to be placed before the consumer in the best possible condition. The old, but unfortunately not yet obsolete, method of suspending nets under the trees into which the fruits are allowed to drop is a bad one, for in addition to the injury which may occur to the delicate skins and flesh, is the fact that a dropped fruit has already lost, or soon will lose, a great deal of its piquancy, and there is no need to let them be on the trees so long. The best way is to examine the trees every morning before the heat of the day, removing carefully all fruits that will yield to gentle pressure and placing them in carefully-padded boxes, which should then be removed to a dry and cool fruit-room. The fruits of some varieties do not part readily from the tree, even when ripe, and for these it is necessary either to use a pad of cotton wool to prevent actual contact with the hand when gathering or to carefully snip through the stem of each fruit with a thin and sharp pair of scissors, holding a pad of the wool in the other hand to receive the fruit. In case it is necessary to pack for sending away this should be done as the fruit is picked and so save one handling. Single layers of fruit in shallow boxes is the best method of packing, and the boxes should be carefully lined up with wood wool or moss to a point which will only just allow for the depth of the fruit, and a single layer of cotton wool over all. Squares of tissue paper should be in readiness and each fruit placed in one of these, so that the base of the fruit occupies the centre of the paper, the sides being drawn up round but not twisted in any way, then the contents can be easily seen and removed by lifting the papers without disturbing the fruits. Small pads of wood wool or moss placed in the angles between the fruits as the work of packing proceeds will prevent rubbing, and is all that is needed, provided the bottom of the box has been properly padded. Cord the boxes instead of nailing down the lids.

Successional peaches should have their growths thinly and regularly placed on the wires, and, as the fruits approach the colouring stage, they should be exposed to light, and with the apex of the fruit upwards ; also pay due attention to watering, giving liquid manure water if desirable, and maintain the soil in a fairly moist condition throughout, as a good supply of water, provided it is not sufficient to sodden the soil, makes all the difference between good and mediocre fruits. In late, cold houses the fruits will soon be ready for final thinning, that is, in places where the fruit is not liable to drop during the stoning period or to injure from any other cause. In my own case I have to leave a surplus for the time being, not because they drop, but owing to a peculiar form of mildew which attacks the fruits in June when they are becoming quite big and most of such fruits have to be removed, as, although sulphur will kill the mildew, a blemish is left on the fruit which detracts from its appearance, so sufficient are left on for the present to allow for the removal of those attacked. This mildew is not the ordinary form of mildew which attacks the peach shoots, but is confined to the fruits alone, and is due, I believe, to a faulty and very draughty structure which has an insufficiency of ventilation in very hot weather, consequently the occupants are exposed to great extremes of temperature.

In mid-season vineries the bunches will have finished stoning, and should have a final examination, cutting out all seedless and surplus berries. At this thinning it is necessary to recognise the question of the size of berry to which each variety swells and thin accordingly, so that the berries may be sufficiently close to render the bunches firm, but not close enough to prevent proper swelling. Young beginners have a tendency to under-estimate the ultimate size of berry, and leave the bunches so thick that the berries become jammed together, by which not only is size lost, but the fruit falls a prey to damping soon after it ripens. After this date it will be possible to ventilate from the side or front lights without much fear of mildew, except when the wind is easterly and cold ; but the advisability of doing so is not apparent in all cases, and will depend greatly on the structure in which the vines are growing. The only general rule that can be laid down for observance is that sharp draughts should never be created. My own opinion is that as regards the vines themselves, independent of other occupants of the houses, no such ventilation is necessary. The present is a capital time in which to plant out young vines that have been retarded for the purpose. It will be found that such vines will overtake those which have been planted earlier, and, as the weather will probably be warm and genial, a good cane is sooner made, and without so much liability to insect pests, as if planted when much fire-heat has to be used. It is also a good time now to inarch vines in mid-season houses, where the wood is beginning to harden, for at this stage a union is easy, and made without danger of injury to the young vine. A long slice taken off from the sides of stock and scion at a point where they can be easily brought to meet, and then binding the two together so that the cut surfaces join is all that is necessary, taking care, however, that the pieces removed are not thick enough to reach the pith at any point.—J. C. TALLACK, *Livermere Park Gardens.*

HYDRANGEA JAPONICA MARIESI, TEMPLE SHOW. (Flowers rose-pink, suffused blue.)

Vegetables in Season.—Looking at a vegetable stall in the Kingston Market a day or two since, I could but be struck with the variety of produce offered for sale, and generally excellent too, at a time of year that is usually regarded as the baldest of the seasons. Thus there were in abundance small well-hearted cabbages, good white broccoli, solid curled kale, spinach, asparagus, sea kale, tomatos, old and new potatos, beets, radishes, lettuces, French beans, mustard and cress, and some other things. Of course, not all of home growth, but still showing in a notable way how abundant were ordinary garden vegetables. No doubt we owe much to the genial nature of the winter through which all vegetables passed unharmed. It is a rare thing to see such a wealth of broccoli heads so late, and shows that new varieties can be of no service if they are not much later in turning in than are the Late Queens, Models, and other good sorts already so plentiful. Really, we have much to be thankful for this spring. —A. D.

HOUSE DECORATION.

THE growth of house decoration, as regards both plants and flowers, during the last twenty-five years has been something marvellous. Twenty-five years ago, even in the mansions of the wealthy, very little was then done in the way of adornment beyond a very limited number of plants, and a still more limited quantity of cut flowers. In fact, at that period it was almost looked upon as sacrilege to cut flowers. In this matter there has been a wonderful revolution, for most people nowadays seem to think flowers are only grown to be cut, and so popular have they become for personal adornment that even the street urchin will be found "swelling" his buttonhole. To meet this rapidly-increasing demand for plants and flowers enormous ranges of glasshouses have been erected all over the country, but chiefly in the vicinity of large fashionable towns. Foreign markets, too, have sprung up to aid in supplying the demand, and the better facilities for transport and delivery, combined with experience in methods of packing, have enabled vendors in this country to place before their customers hyacinths, tulips, narcissi, and many other flowers almost as fresh as when cut. Of course, the home grown article is always best when it is possible to obtain it, but this is not in sufficient quantitities at command at all times, for an extensive grower remarked the other day to me that they were waiting for the flowers to open to cut them.

Although many of the flowers seen in our markets are of foreign growth, plants are nearly all of home production, as evinced by the huge nursery establishments devoted to their culture. For example, the nursery firm of Messrs. Dickson (Limited), Chester, have a field of glass for the purpose of meeting the requirements of their extensive business in the three kingdoms, with private customers, and the public demands at home. The subjects which seem to be in greatest favour for house and indoor window adornment are palms, and of these the Messrs. Dickson grow millions. In the various ranges of glasshouses they utilize for palms the most fastidious can be satisfied, for plants, from cotyledon to the size of twelve feet in height, can be selected. This public taste for green plants with bold or elegant foliage, either for the cottager or the lord, in adding life and beauty to their homes, speaks well for the discriminating powers of both, as no class of plants looks better or lasts longer in a healthy state than palms. This last remark, however, refers only to well grown plants—plants with abundance of sturdy, healthy foliage—such as are seen at Chester, and not those drawn and bleached by excessive heat and want of light. Among the more select palms that I saw in Messrs. Dickson's nurseries were Acanthophœnix crinita, a lovely subject for dinner-table decoration in a young state ; and Pritchardia pacifica. Of these there were a representative lot, not but that Acanthophœnix crinita is likely to become of general use in private gardens when better known. The older and better known sorts were in their thousands, of which I noted Areca Baueri, lutescens, monostachya, sapida, and Verschaffelti, Calamus ciliaris, Caryota urens, Chamærops fortuni and humilis, Cocos plumosa and Weddelliana, Dypsis madagascariensis, Geonoma gracilis, Kentias in variety, Latania borbonica and rubra, Phœnix reclinata, rupicola, sylvestris, and tenuis, Rhapis flabelliformis, Sabal nubraculifera, Seaforthia elegans and robusta, Thrinax elegans, and Verschaffeltia splendens.

Even among these generally well known species a selection may be made of those that are most suitable, both as regards powers of endurance and effectiveness, for the cottage window and the castle. Therefore, I would include in the twelve best suited for all Areca lutescens and lapida, Chamærops humilis, Cocos Weddelliana, Corypha australis, Kentia australis, Belmoreana, and Fosteriana, Latania borbonica, Phœnix reclinata and sylvestris, and Seaforthia elegans. The amateur will find Chamærops humilis, Corypha australis, Phœnix reclinata, and Latania borbonica the ones which will do best with him. Cocos Weddelliana is such a graceful plant that many fall in love with it at sight, but unless it can be given a stove temperature and only used for house decoration for short periods occasionally, it will become a short lived subject. It is one of the more tender palms, and also one requiring skill to grow it successfully. CESTRIAN.

ANSWERS TO CORRESPONDENTS

Editorial communications should be addressed to the Editor of the Gardeners' Magazine, 148 and 149, Aldersgate Street, E.C.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, &c., for reproduction in the Gardeners' Magazine. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the Gardeners' Magazine, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning change of dates

Pansies.—J. Y., Desborough: We do not recognise the particular strain from which the flower sent was obtained. It is a fancy variety, and very pretty by reason of its wire edge, but it would not successfully compete with the well-known varieties you mention. Fancy varieties would certainly be the most effective—other things being equal—in a class for twelve blooms of any variety or form of pansy.

Border Carnations.—J. Y., Desborough: Any carnation is a border variety that is quite hardy, has a robust habit, flowers freely, and requires the minimum of support. The flowers must be bold and the colour effective. Not a few of the best exhibition carnations make fine border varieties. Of course, for exhibition purposes, border varieties have to be cut from the border where they have been grown unprotected.

Repairs to House.—J. G., Liverpool: In the absence of any written agreement to do so the landlord is not bound to execute repairs. If the trustees do not repair the structure you will not be justified in withholding the rent; you might, however, put the matter to them in a reasonable manner, explaining the verbal agreement of the deceased landlord; then, if they still object to execute the necessary repairs, you could give notice to quit. Rent would have to be paid up to the end of tenancy, but meanwhile, unless to your advantage to do so, you need not do any repairing, having entered into no agreement to do any.

Heating Apparatus.—A. R. R., Orpington: The boiler should be set level, and it will be advisable to have a competent workman to do the work, otherwise a poor job may be made of it. The flow pipes should rise about an inch in every thirty feet, and there should be a corresponding fall in the return pipe. Different forms of boilers give different powers of heating; consequently, it will be best to inquire of the boilermaker what the capacity of his design is, the depth at which the boiler should be set, and the amount of rise and fall in the pipes necessary to insure a good circulation.

To Prepare Quassia.—A. L. M., Halstead: The best and most economical method of preparing a quassia insecticide out of the quassia chips obtainable from horticultural sundriesmen is to soak the chips in cold water for twenty-four hours, and then gently simmer the whole for ten or twelve hours. From eight to ten pounds weight of good quassia wood should be sufficient for one hundred gallons, and to this should be added about five pounds of soft soap. Some of the soap should be used in the water when the chips are stewing, as it helps to extract the bitter principal. If the amount of chips mentioned are used, as much water as can conveniently be managed will do to soak and simmer them in, adding the water to make up the hundred gallons, and the remainder of the soap, dissolved, after straining the mixture from the chips. Quassia is a useful preventive of insect attacks, and has a most cleansing effect upon foliage; but there are other mixtures more effective and easily produced for use as remedies when an attack of aphis has been made.

Cooking Californian Prunes.—G. W., Canterbury: As a rule the great mistake made in the preparation of dried Californian prunes for table is the small amount of time allowed the fruit to soak in water. It requires about two and a-half pounds of these prunes to make one pound of the dried product, and these fruits are exposed to sunshine for about a week during the drying process. When we consider the time necessary to extract the water from the fresh fruit ere it is ready for packing it is manifestly unfair to expect the dried fruit to properly plump up in the two or three hours during which they are usually soaked. Try the following method for stewing Californian prunes: To one pound of fruit, thoroughly washed in several waters and drained, add three pints of cold water, and allow them to soak for from twenty-four to thirty-six hours. Eventually place the prunes in a porcelain-lined stew-pan and allow them to simmer gently for a little less than an hour in the water in which they were soaked. Keep the stewpan covered closely during cooking, and if any sugar is needed add this a few minutes before the fruits are properly cooked, and allow the whole to boil for a minute. Turn it out into a dish and keep covered until cool. The result will be about four pounds of excellent fruit.

Nitrogenous Manures.—W. F. H.: In the cultivation of hardy fruits as in the case of other crops, it is a mistake to supply an excess of nitrogen, even though potash and phosphates are present in sufficient quantities. If more nitrogen be present in the soil than the crop needs, the tendency will be to produce wood and leaves instead of fruits and seeds. In the case of fruit trees an excess of nitrogen will cause them to continue growing too late in the season to admit of the maturation of the wood and the production of properly developed flower buds. For the majority of soils the proportion of one part of nitrogen to one part of phosphoric acid, and three parts of potash will be the most suitable. You should also remember that as nitrogen is the most costly element, and the most liable to loss, it should, whether in the form of nitrate of soda or sulphate of ammonia, be applied with care, and as far as practicable, in exact accordance with the requirements of the trees or plants. There has been considerable discussion of late in America as to whether liberal applications of phosphates and potash would be beneficial where nitrogenous manures had been used too liberally, but as yet nothing approaching an agreement has been reached. There, however, appears to be a preponderance of opinion, and, as we believe, rightly so, that orchard trees are benefited by applying phosphates and potash when an excess of nitrogen has been used, as these minerals help to produce a more perfectly developed wood. A soil that is rich in mineral matters will have its fertility greatly increased by a moderate dressing of sulphate of ammonia or nitrate of soda. Nitrate of soda does not exhaust the land in the manner commonly supposed, but if the supply of mineral constituents is limited, a continuous application of nitrate of soda or other form of nitrogen will by promoting a rapid growth enable the crop to use up the minerals and thereby impoverish the soil. The exhaustion is not caused by the nitrate of soda, but from the fact that the crop has used up the available supplies of plant food. In the case of the majority of garden crops, it is advisable to apply quick acting nitrogenous manures at intervals throughout the period on growth; but with fruit trees the best results are obtained by giving sufficient in one or two dressings early in the season to promote active growth, as when this is done the trees take it up in a comparatively short time, leaving the remainder of the season for the maturation of the wood. It is essential to avoid supplying the trees with nitrogen in excess of their requirements, and especially late in the season.

Mildew on Strawberries.—E. S., Hailsham: It is quite evident that the strawberries have been subjected to atmospheric conditions much too moist and close for their successful fruiting. They have also been staged too closely together, and evidently not allowed sufficient light to strengthen the foliage and perfect the berries. If there is the slightest sign of mildew upon strawberry foliage ere the plants are taken in for forcing, the leafage should be dipped in a sulphur mixture that will stay the fungus. Then, also, if the pest appears after housing, further dippings may be given until the spikes come forward, after that it will be necessary to apply flowers of sulphur or liver of sulphur through a distributor to the parts affected. With stout, well ripened crowns and clean foliage to start with, there should be no difficulty in forcing strawberries for providing fruit at this date, but with so many other subjects in the same house, there is too much moisture at the times of setting and ripening.

Lime for Clayey Soil.—T. E. R., Hull: Lime has a wonderful effect upon heavy clay soils and exerts a mechanical, as well as chemical, action. Lime renders clay soil friable by mixing with the particles and preventing the condition known as "puddling." It also keeps the soil friable in dry weather, for whereas the clay shrinks and hardens in the absence of moisture, the lime does not shink. If you require direct evidence of the mechanical power of lime knead up a ball of pure clay with water and allow it to dry, then, with similar clay, add a little lime and make a ball as before, also setting it to dry. When dry the ball of pure clay will be as hard as a brick, while the ball of clay and lime will crumble readily to powder. Then by its chemical action lime disintegrates the minerals in the soil and sets free the potash for use to the crops. It also exerts a wonderful action upon decomposing vegetable matter, causing the otherwise inert nitrogen to become available as plant foot. All soils containing abundance of organic matter are rendered more fertile by an application of lime, or rather, the fertility is rendered more available to the plants. Again, lime neutralises acidity, and consequently makes a sour soil sweet and healthy. Poorly drained lands are assisted by lime dressings. Lime also promotes the natural formation of nitrates, and is consequently of great vulue on peaty soils.

Names of Plants.—Under this heading we can only undertake to name species and specific varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp moss or leaves as packing material to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that the numbers be legible and firmly attached to the specimens. We cannot promise to name more than six specimens at one time from any one correspondent.

J. M., Merstham: 1, send again; 2, Piptanthus nepalensis; 3, variety of Pernettya mucronata; 4, Berberis vulgaris var.; 5, Berberis Darwini; 6, Amelanchier botryapium.

A. B., Fawley: 1, Psoralea arborea; 2, Spiræa prunifolia flore plena; 3, Dielytra spectabilis; 4, Anthriscus cerefolium; 5, an anthemis, send when in flower.

MARKETS.

Covent Garden.

Vegetables are both abundant and cheap, while the quality is all that can be desired. Broccoli are especially good and sell well. The turn of warm weather has increased the demand for salading, as also of green-stuffs generally. Potato trade moderate. Cut flower trade brisk.

Fruit.—Tasmanian apples, 10s. 6d. to 16s. per case; bananas, 5s. to 10s. per bunch; oranges, 15s. to 18s. per case; Jaffa, 10s. to 12s. per box; English grapes, 2s. to 4s.; Belgian, 1s. to 1s. 9d. per lb.; lemons, 6s. to 15s. per case; English tomatos, 6d. to 9d. per lb.; Canary, 10d. to 1s. 4d. per tray, 2s. 6d. to 3s. 6d. per case; strawberries, 2s. 6d. to 3s. 6d. per basket; gooseberries, 2s. to 3s. per basket; cherries, 1s. to 1s. 3d. per box; green figs, 3s. 6d. to 5s.; peaches, 6s. to 12s. per dozen; pineapples, 1s. 6d. to 4s. per pine.

Flowers.—Arums, 3s. to 4s.; carnations, 1s. to 3s.; eucharis, 3s. to 4s.; gardenias, 1s. to 3s.; Lilium Harrisi, 3s. to 4s.; tea roses, 6d. to 1s.; pink roses, 3s. to 6s.; red roses, 2s. to 4s.; cattleyas, 6s. to 9s.; Odontoglossum crispum, 1s. 6d. to 4s.; and tuberoses, 1s. to 1s. 6d. per dozen blooms; Adiantum cuneatum, 4s. to 8s.; marguerites, 2s. to 4s.; narciss, various, 1s. to 3s.; daffodils, 1s. 6d. to 4s.; tulips, 3s. to 6s.; mignonette, 2s. to 4s.; pelargoniums (scarlet), 4s. to 6s.; wallflowers, 2s. to 3s.; polyanthuses and cowslips, 1s. to 1s. 6d.; primroses, 9d. to 1s.; bluebells, 6d. to 8d.; and violets, 9d. to 3s. 6d. per dozen bunches; azaleas, 6d. to 9d.; stephanotis, 4s. to 6s.; lily of the valley, 6d. to 1s.; and pelargoniums, 4d. to 6d. per dozen sprays; bouvardias, 6d. to 8d.; white lilac, 3s. to 4s. per bunch.

Vegetables.—English asparagus, 1s. to 3s. 6d.; Spanish, 9d. to 1s.; French, 1s. 3d. to 2s. per bundle; spring cabbages, 6d. to 9d.; cauliflowers, 1s. to 2s.; endive, 1s. 4d. to 1s. 8d.; cabbage lettuce, 6d. to 9d.; cos lettuce, 1s. 6d. to 2s.; cucumbers, 2s. to 4s. 6d. per dozen; carrots, 3s. to 5s.; turnips, 4s. to 6s.; mint, 3s. to 4s.; parsley, 1s. 6d. to 1s. 9d.; spring onions, 1s. 6d. to 2s. 6d. per dozen bunches; Egyptian onions, 5s. to 6s. 6d. per cwt.; beetroots, 2s. to 3s. per tally; green peas, 2s. 6d. to 3s. 6d. per pad; French beans, 3d. to 4d. per lb.; mushrooms, 6s. to 8s. per 12 lb.; rhubarb, 1s. 6d to 2s. 6d. per dozen bundles; Canary potatos, 9s. to 12s.; Malta round, 8s. to 10s.; Algiers, 14s. to 16s. per cwt.; French, 2d. to 2½d. per lb.

Borough Potato Market.

The demand for new potatos is increasing, as also is the supply. Prices remain unaltered for both new and old. Dunbars, 130s. to 140s.; Scotch Magnums and Hebrons, 110s. to 120s.; Bruce, Main-crop, Sutton's Regents, Reading Giants, and Saxons, 100s. to 110s. per ton; Belgians and Germans, 4s. 9d. to 5s. 3d. per bag. New—Maltese rounds, 9s. to 10s.; Teneriffe kidneys, 12s. to 13s.; Jerseys, 1[illegible]s. to [illegible] per cwt.; Lisbon rounds, 5s. 6d. to 5s. 9d. per box.

(*Continued from page* 340.)

[illegible] prunus and acers with coloured foliage, assisted the bamboos to make a [illegible] background, while on either side of the central mound were large plants of [illegible] varieties of Azalea mollis and A. sinensis. A light scarlet form of Azalea [illegible] named Mikado much was *en evidence*, as were the hydrangeas, notably H. japonica rosea and the large-bracted form named Mariesi, figured herewith. In the foreground were baskets of Philadelphus coronarius Boule d'Argent, white; Ceanothus Veitchianus, clothed in small spikes of blue flowers; Vitis heterophylla variegata, very elegant; Philadelphus Lemoinei; Azalea glauca stricta, very free and with white honeysuckle-like flowers; Andromeda speciosa cassinefolia, with drooping white flowers; and the brilliant yellow Azalea Anthony Koster. Standing up amid all these and many other choice subjects were standards of Cytisus scoparius Andreanus, C. s. præcox, Rosa Wichuriana Manda's Triumph, standard wistarias, and a number of bold spikes of the bold Eremurus himalaicus.

A pretty bank of hardy rhododendrons came from Messrs. J. Waterer and Sons, Bagshot, Surrey; this was set up in the big marquee, and contained some remarkably beautiful varieties; the standards of Cynthia, rich pink; Kate Waterer, rose and buff; Madame Carvalho, white; John Waterer, scarlet; Countess of Normanton, blush and rose; Baroness de Rothschild, scarlet and pink; and Gloriosum, pale blush, were remarkable for their bold trusses and fine blooms. Dwarfer plants of equal beauty were Duchess of Connaught, Countess of Ilchester, pink, margined with scarlet; Pink Pearl, and Fastuosum with a bluish-purple tint. Messrs. J. Cheal and Sons, Crawley, put up a pretty exhibit in one of the large beds on the grass near the entrance; this consisted of several specimens of rhododendron Fred. Waterer, Azalea amœna splendens, lilacs in variety, Mollis azaleas, brilliantly-coloured Japanese maples, elegant conifers, including Cupressus Lawsonianus filifera glauca, Cornus Spathi, golden yews, coloured beeches, and many other choice ornamental trees and shrubs, notable for their fine foliage or their handsome flowers.

In addition to their large, crescent-shaped groups, Messrs. Fisher, Son, and Sibray had a star-shaped group of their charming maples and ivies. In the larger display there was a background of golden oaks, Cornus siberica elegantissima, a mass of silver and gold foliage, and before these were arranged a collection of at least thirty distinct varieties of Japanese maples, including all the well-known and popular palmatum and dissectum forms, and also a fine lot of A. palmatum [illegible]. Larix leptolepsis is a tree that has a great future before it, being hardier and yet a more vigorous grower than the Tyrolean larch; as an ornamental plant it is also likely to be in demand. Another fine subject is the purple peach, a free grower, and with fine red-purple leafage. Other effective plants, bush ivies, Ulmus Wreedi aurea, and the large-leaved Quercus macrophylla; Q. concordia, the Golden Oak; Betula purpurea, the purple birch; and Weigelia Looymannsi aurea, the latter worth growing alone for its bright foliage. Messrs. Fisher, Son, and Sibray excelled their effort of the previous year, and set themselves a task for the future. Messrs. J. Waterer and Sons, Bagshot, Surrey, were large exhibitors of the deservedly-popular and extremely-elegant Japanese maples, showing pleasing specimens of all the principal varieties already [illegible] with reference to other displays; particularly notable were the specimens of Acer palmatum argenteum, A. p. ornatum, A. p. involutum, a small, [illegible] divided green form; and A. dissectum purpureum, a cascade of finely-[illegible] red-purple foliage.

Japanese maples were well shown by Messrs. W. Fromow and Son, Sutton Court Nursery, Chiswick, who arranged a choice set of well-grown plants with pure white liliums. The most interesting maples were Acer palmatum sanguineum, A. dissectum reticulatum, A. d. purpureum, A. palmatum marmoratum, A. dissectum variegatum, and A. palmatum aureum. Aralia pentaphylla variegata made a charming edging to a group of charming and handsome foliaged plants. An attractive lot of mollis and sinensis azaleas, shown by Messrs. R. and G. Cuthbert, Southgate, made a fine gleam of rich colour at the Temple end of the No. 4 tent. The mollis forms were of especially high quality, and every plant was a compact bush smothered in brilliant flowers. Alphonse Lavallee, salmon scarlet; Comte de Quincy, pale yellow; Anthony Koster, rich yellow; General Vetter, orange tinted; Baron Pycke, rich red, were among the most attractive. There were also very fine bushes of rustica forms, all remarkable for their floriferous habit and general effectiveness. The Messrs. Cuthbert had a fine selection of good hardy azaleas.

One of the groups out of doors was arranged by Mr. John Russell, Richmond Nurseries, Richmond, Surrey. In this there were a number of elegant Acer [illegible], and tall standard Japanese maples, chiefly red and purple foliaged forms of the dissectum and palmatum sections. The ivies were very bright, especially Russell's Silver, a charming form; Lees' Silver, Palmatum aureum, and Arborea Silver Queen, particularly handsome. Euonymus latifolius albus formed an attractive marginal band to this interesting group. From Messrs. Little and Ballantyne, Carlisle, came a basket of small plants of Golden King Holly, a [illegible] form and a sport from the Hodgson Holly, the foliage is broad and the [illegible] are turned under the leaf save in the young foliage. The older leaves have [illegible] marking on a creamy ground, but the new leafage is bright golden [illegible] and pale green; a good holly and one that has proved perfectly hardy at [illegible], and a vigorous grower. A group of bamboos and hardy rhododendrons was arranged in a star-shaped bed out of doors, and created much interest. The rhododendrons were Fortunei hybrids, and everyone a mass of brilliant flowers. The bamboos both tall and dwarf were remarkable for their grace, and as these are now becoming popular, the group commanded a good deal of attention.

Stove Plants.

Messrs. F. Sander and Co., St. Albans, had a group of new plants that attracted a vast amount of attention; this occupied the extreme end of the central [illegible] of the large marquee, and consisted chiefly of the new, curious, and handsome [illegible] Sanderi, carrying an abundance of its long depending crimson tassels, [illegible] in previous issues and figured in the present; Dracæna Van der Billi, [illegible] leaved and elegant form with white margined foliage; Licuala Jeanenceyi, [illegible] Sanderi, Anthurium Novelty, with scarlet leafage; Acalypha God-[illegible], with creamy-green margin to the neat foliage; the now fairly well known [illegible] Godseffiana, and the erect D. Sanderiana made up a group of great [illegible] and interest; one other plant of great beauty was that most elegant of date [illegible], Phœnix Rœbelini. A number of anthuriums gave colour to this exhibit.

A small group of the curious and attractive anthuriums came from M. de Smet [illegible], Mont St. Amond, Ghent; all were seedlings from or variations of Anthurium Scherzerianum, and a remarkable feature was the large percentage of [illegible]-spathed scapes. Some notable varieties were Baron Schröder, with a [illegible] and intense scarlet spathe; De Smet Duvivier, with crimson spathe; [illegible] Montefior Levis, scarlet spotted, on a white ground; Rotundiflorum, [illegible] round spathe; and Prince Albert, a fixed twin-spathed, or even triple-[illegible] form of a rich crimson colour. This little group of anthuriums attracted [illegible] of the curious, and was recognised as a most novel display.

In tent No. 4 Messrs. J. Veitch and Sons, Chelsea, arranged a handsome group of crotons on the ground: the specimens were of fair size, clean, well furnished, and brightly coloured; leading varieties were Queen Victoria, the broad-leaved Readi Warreni, with graceful twisted leafage, Eugene Chantrier and Albert Truffant, both with large and bright foliage; Aigburth Gem, Hawkeri, Golden King, Sunbeam, Sunshine, Sinitzianum, and Prince of Wales. An effective group was arranged by Mr. W. Iceton, Granard Nurseries, Putney Park Lane, S.W., and was greatly admired. Kentias, raphis, and cocos, palms, bamboos, and Araucaria excelsa made a bold and graceful background and centre, with clumps of pure white liliums disposed among the greenery. Crotons, gaily coloured; caladiums with broad handsome foliage, heaths, lily of the valley, Otaheite oranges, crassulas, and Azalea mollis were tastefully disposed in the foreground, with raised plants of Dracæna Doucetti and D. Sanderiana. A new and graceful dracæna from Messrs. Dickson, Chester, will no doubt soon be sought after as a table plant, for it is light and graceful. It is named D. Kippsi, and has narrow, curved leaves of a deep purple green, margined, lined, and streaked with deep red. Messrs. J. Laing and Son, Forest Hill, sent two new dracænas, named Rose Laing and Distinction, the former is very handsome, and has been previously described in these columns.

Tuberous Begonias.

The splendid bank of tuberous begonias arranged in the third tent by Mr. T. S. Ware, Tottenham, consisted almost entirely of double forms, and these were of a very high standard of excellence throughout. In form and colour the varieties left nothing to be desired, while the habit of the plants, so dwarf and stocky, was the subject of considerable comment. Fringed and picotee-edged sorts have been much developed during the year, and there appeared to be a greater predominance of the camellia flowered forms than usual. A few good doubles that attracted our attention during a rapid inspection were Mrs. Dumbar Wood, deep yellow; Brilliant, orange scarlet; Golden Queen of England; Samuel Pope, cream, with pink margins; Princess of Wales, creamy pink; Advancement, a curiosity in pink and cream and scarlet; Mrs. S. Pope, pure white; Reynolds Sharp, scarlet; and Beauty of Bexley, salmon.

Tuberous begonias were finely staged by Messrs. J. Laing and Sons, Forest Hill, who set up a long bank of remarkably well-grown stuff, staging the varieties in little groups so as to produce an undulating whole. Single sorts were prominently good, and among these Mrs. J. Pierpont Morgan, yellow; Mrs. Davis, apricot; Earl of Aberdeen, crimson; Countess of Aberdeen, white; General Lockhart, salmon, with flowers six and a quarter inches across; and Marchioness of Salisbury, yellow, were exceptionally fine. Duke of Fife, Mrs. Griffiths, fringed and waved, white; Lady Tweedmouth, carmine; Lady Gifford, salmon-pink; and Lady Charles Beresford, rich red, were a few notable and handsome double varieties out of a large collection of fine forms.

A grand bank of begonias from Mr. J. R. Box, West Wickham, was evidence that this exhibitor is in the front rank of raisers and cultivators of the tuberous begonias, The single varieties were remarkable for the size, form, and brilliance of their flowers; and the double sorts, notable for their stocky habit, and full, elegant, and substantial blooms. Miss Leanard, cream; Zelinda, orange; Hogarth, orange scarlet; and Eureka, yellow, were especially good double varieties; while of the named single sorts, Proserpine, deep rose; Beloma, white, Magnitude, rose; and Canary, yellow, were the most prominent and handsome. A fine lot of tuberous begonias was staged by Mr. H. J. Jones in No. 4 tent, and made a most effective attractive bank near one of the entrances. The great variety of shades of colour represented in this collection was a great feature for Mr. Jones had all shades of crimson, scarlet, orange, yellow, cream, white. pink, salmon, and rose, as well as combinations of several colours. Both single and double begonias were brought from the Ryecroft Nurseries, and on many there was an exquisite fringing that added to the general beauty of form and colour: Star, pink; Mrs. Beckett, salmon; Delight, rose; Primrose Queen May Manser, rose and scarlet; Dr. Shaw, orange scarlet; Ryecroft, salmon buff; Beacon, a lovely crimson; and Novelty, a curious shade of apricot-orange, were the pick of the singles.

Cacti.

The display of phyllocacti by Messrs. James Veitch and Sons, Chelsea, was certainly the most novel exhibit at the Temple Show, and no other excited more interest or drew forth more admiration from the visitors. A wonderful improvement has been made in these during the past few years, and now we may have plants in forty-eight sized pots carrying three of four huge flowers in various stages of expansion, each flower lasting in perfection for three or four days. The colours are as numerous as one could well wish; there are pure white flowers, cream, pink, rose, red, scarlet, orange tinted, pale crimson, salmon, and some with purple shading. The blooms are about seven inches across, and composed of several rows of broad segments around a central tuft of elegant stamens. The foliaceous stems are themselves not devoid of beauty, and certainly the group of plants shown in flower presented no incongruity of flower and leaf, but rather a most brilliant and charming effect that approached gorgeousness, and would have been excessively bright but for the lighter colours and delicate shades associated with the richer forms. Altogether Messrs. Veitch staged between four and five hundred plants in their group, and are to be congratulated upon their fine display.

Mr. G. J. Pritchard, Godwin Road, Forest Gate, exhibited a somewhat large and very interesting collection of cacti, a novel exhibit in which the specimens of Echinocactus aureus, E. Grayssoni, a melocactus, Cereus flagelliformis, C. geometrizans, Pilacereus senilis, Mamillaria Kleimschmidti, Opuntia microdasy, and O. maxima attracted most attention.

Gloxinias.

A brilliant lot of gloxinias was submitted by Messrs. J. Veitch and Sons, who showed splendidly-flowered plants, representing a grand display of beautiful varieties and plants of the very best habit and growth. Achille, white and red; Mars, scarlet; Virginale, white; Triton, purple and crimson; Seraph, scarlet and pink; Cordelia, rose-spotted on white; Aveline, pale pink and cream; Monarch, rich red; Galatia, blush; and Eclatant, scarlet and white, attracted our attention most. Gloxinias in variety were arranged in a bed of ferns by Messrs. J. Laing and Sons, Forest Hill; for the depth of colour, fine shape, and robust growth, the Forest Hill strain is well known. A new form in which crimson and purple were peculiarly associated in the body of the flower, and with the broad white margins to the segments, spotted with purple, was a most distinct advance in a new direction, and promises us a new shade of colour—interesting combinations. The Messrs. Cannell and Sons, of Swanley, displayed their excellent strain of gloxinias in an admirable way, by arranging a moderate number of well-grown and freely-flowered plants in a bed of maidenhair fern. This allowed one to fully comprehend the decorative capacity of each plant, and revealed that not only were the flowers of fine colour or exquisite shape and mottling, but that the plants possessed a first rate habit. White Queen, Princess of Wales, Prince of Wales

Maude, and Mrs. Marshall were especially good forms. Messrs. J. Peed and Sons, Roupell Park Nurseries, Norwood, had a choice display of gloxinias, their collection containing a large percentage of charming and beautifully spotted forms. Majestic, Exquisite, pink spotted; Duchess of York, Princess of Wales, Queen of My Heart, and Mrs. W. Weaver, a lovely pink, were the pick of these, while Royal Purple, Empress of India, Mr. G. W. Sawday, Aigburth Crimson, Beacon, Petunia, and Jasper were particularly handsome selfs or shaded forms; the latter was a grand flower, and very rich. A small group of erect-flowered gloxinias in considerable variety was staged by Messrs. A. Young and Co., Stevenage, at the end of their large group.

Pelargoniums.

Mr. J. Pope, Royston, Herts, sent a new seedling show pelargonium named Agnes Alma. This is semi-double, of large size, and of a rich scarlet hue, shaded with brown and pink. Mr. A. Tulett, Crocker Hill, Swanley, arranged a bank of bright, scarlet-flowered pelargoniums, the variety being a richly-coloured sport from F. V. Raspail, and named A. Tulett. Mr. Charles Turner, Royal Nurseries, Slough, contributed some finely-grown and freely-flowered show and fancy pelargoniums, using them to flank his large rose exhibit. Popular sorts, such as Edward Perkins, Lady Isabel, St. Blaise, Magpie, Iona, The Shah, Joe, Mystery, Maid of Honour, and Prince Leopold were most in evidence, and the way in which they were admired showed that the love for such plants has not much diminished. Messrs. A. Young and Co., Stevenage, made a brilliant display with their new semi-double salmon-coloured zonal pelargonium, King of Denmark.

Calceolarias.

Messrs. J. James and Son, Farnham Royal, well sustained their reputation for excellent strain of calceolarias, for their group of these highly decorative plants was admired by all visitors to the show. Every specimen was a model of good culture and dwarf compact habit, while the huge trusses of big blooms were remarkably fine. Both selfs and spotted forms were arranged, and it is a difficult matter to decide which are the most elegant, and opinion among the visitors seemed equally divided upon the subject, though all were agreed that the general quality of the strain was A 1. Very gorgeous were the handsome calceolarias exhibited by Messrs. H. Cannell and Sons, Swanley; these occupied a prominent position in No. 4 tent, and formed a centre of attraction. The colours were good, the flowers were full-sized, and the plants of fine vigorous habit, though at the same time compact and handsome. The intense scarlet and crimson forms from Swanley attracted our attention the most, but the others were no less beautiful. Messrs. J. Carter and Co., High Holborn, had a huge exhibit occupying the whole of the centre of the tent. There were masses of gorgeous calceolarias, mounds of chaste liliums, graceful spiræas, bright streptocarpuses, showy petunias, fragrant mignonette, glowing begonias, dwarf cut sweet peas, irises, anemones in variety, and parrot tulips. In addition to beauty in flowers and plants this firm also catered for other tastes, staging splendid Duke of York tomatos, Stratagem peas, climbing French beans, Model cucumbers, and other choice vegetables and salading; the Duke of York tomatos in pots were thoroughly well cultivated, and looked well with their big racemes of fruit.

Carnations.

A novel and attractive disposition of carnations, azaleas, crimson Rambler roses, spiræas, yellow richardias, and Browallia elata was made by Messrs. W. Cutbush and Son, Highgate, N., and Barnet, Herts. This firm occupied a corner in the big marquee, and put up one of the most tasteful displays in the show. There were valleys of malmaison carnations, slopes of golden and creamy azaleas, mounds of the blue Browallia elatior, and hills of brilliant border and show carnations, and mountains of Rambler roses, spiræas, bamboos, and palms. Liliums were dotted here and there, with a few Calla Elliottiana, the golden arum. Mrs. Andre Campbell, Waterwitch, Uriah Pike, The Gift, Cardinal Wolsely, La Villette, Souvenir de la Malmaison, Princess May, and G. B. Bryant were a few of the best carnations we noted in this large and excellent collection.

A grand lot of pink-flowered Souvenir de la Malmaison carnations occupied the end of the central staging in the large marquee, and these came from Ascott, Leighton Buzzard, where Mr. J. Jennings is the able gardener to Leopold de Rothschild, Esq. The flowers were of large size and finely coloured; they were chiefly in 16-sized pots, and carried on an average eight blooms and buds apiece; a very fine lot. A charming lot of carnations were set up by Mr. Charles Turner, Slough; they were admirably flowered, and consisted largely of seedlings and yellow-ground fancy forms; Knight Errant, rich scarlet; Queen of Fancies, yellow and rose; Ernest, yellow; Delos, scarlet; Buttercup, yellow; Desdemona, pink; and Little John, rich scarlet, were the most notable named forms.

Messrs. Dicksons, Chester, staged a number of plants of their new yellow tree carnation Duchess Consuelo, a form that has been shown under the name of Admiration, and given an award of merit as such on a previous occasion. This is a tall and robust grower carrying enormous rich yellow flowers.

Mr. Perkins, Regent Street, Leamington, put up a group of especially well grown carnations; this display consisting of ten large specimens of a fine yellow form named Primrose Queen, very free, of large size and great substance; a beautiful and free carnation.

Silver Cups.

Silver cups were awarded as follows: to Messrs. Jackman, for clematis and herbaceous plants; Messrs. R. Smith, for clematis; Messrs. Barr and Son, for herbaceous plants; Messrs. Cutbush, for foliage plants, palms, and carnations; Sir Frederick Wigan, Bart., for orchids; Messrs. Charlesworth and Co., for orchids; Messrs. Hugh Low and Co., for orchids; Messrs. Sanders, for orchids and new plants; H. S. Leon, Esq., for orchids; Earl Percy, for orchids; Messrs. Linden and Co., for orchids; Mr. J. Cypher, for orchids; Mr. J. R. Box, for begonias; Messrs. Paul and Son, for roses, &c; Mr. C. Turner, for roses, pelargoniums, and carnations; Mr. Beckett, gardener to Lord Aldenham, for vegetables; Sir J. Pease, Bart., for fruit; Messrs. J. Rivers and Son, for pot fruit trees; Messrs. Sutton and Son, for vegetables; Messrs. J. Carter and Co., for vegetables and flowering plants; and to Messrs. H. Cannell and Son, for cannas, gloxinias, calceolaria, begonia, &c.

Medals Awarded,

Golds medals were awarded to Sir Trevor Lawrence, Bart., or orchids; to Messrs. W. Paul and Son, for roses; to Mr. George Mount, for roses; to Messrs. James Veitch and Son, for caladiums, crotons, cacti, gloxinias, &c.; and to Mr. Hudson, gardener to Leopold de Rothschild, Esq., for pot fruit trees.

Silver-gilt Knightian medals to Messrs. George Bunyard and Co., for apples, &c.; Mr. Empson, gardener to Mrs. Wingfield, for vegetables; and to Mr. S. Mortimer, for cucumbers and tomatos.

Silver-gilt floral medals to Mr. T. S. Ware, for herbaceous plants; Messrs. Perkins, for bouquets, &c.; Messrs. H. B. May, for ferns; Messrs. B. S. Williams, for orchids and decorations; Messrs. Lewis and Co., for orchids; W. Thompson, Esq., for orchids; Jules Hye Lyeson, Esq., for orchids; Leopold de Rothschild, Esq., for carnations; Messrs. W. Blachin and Son, for Leschenaultia, &c.; Messrs. James, for calceolarias; Messrs. Fisher, Son and Sibray, for hardy foliage plants; Messrs. Kelway and Son, for pæonies, &c.; Messrs. J. Laing, for gloxinias, streptocarpus, &c.; Messrs. J. Peed and Sons, for caladiums, &c.; and to Messrs. J. Waterer and Co., for rhododendrons; and Messrs. Cheal and Sons, for shrubs.

Silver-gilt Banksian medals to Ludwig Mond, Esq., for orchids; Mr. H. J. Jones, for begonias; F. Cant and Co., for roses; Messrs. W. Rumsey, for roses; Messrs. Backhouse, for alpines, &c.; Messrs. R. Wallace, for hardy plants, &c.; Mr. George Edom, for tulips; Mr. J. Pritchard, for cacti; Mr. M. V. Seale, for decorations; Messrs. J. Hill and Son, for ferns; Messrs. W. and J. Birkenhead, for ferns; Malcolm S. Cooke, Esq., for orchids; and to Mons. L. de Smet Duvivier, for anthuriums.

Silver Knightian medals to Horticultural College, Swanley, for vegetables; Mr. G. Featherby, for fruit; and to Mr. Hayes, gardener to the Marquis of Northampton, for vegetables.

Silver Flora medals to Messrs. I. House and Son, for violas; Messrs. A. Young, for gloxinias, &c.; Mr. A. Perry, for herbaceous plants; Mr. Moyes Stevens, for bouquets, &c.; Mr. W. Sydenham, for violas, &c.; Mr. L. A. Calcutt, for decorations; Mr. J. Prewett, for decorations; Messrs Jones and Sons, for decorations; Mr. John Russell, for azaleas, &c.; Mr. M. Prichard, for herbaceous plants; Messrs. F. Miller and Co., for mignonette, &c.; Mr. R. Cuthbert, for azaleas; Messrs. Fromow and Son, for maples; Mr. W. Iceton, for foliage plants; Jadoo Company (Limited), for plants; and to Messrs. Cripps and Son, for maples.

Silver Banksian medals to Mr. Koster, for azaleas; Mr. A. Tullett, for zonals; Mr. E. G. Reid, for rhododendrons; Mr. F. Chapman, for asparagus; Lord Foley, for strawberries; Mr. A. Henderson, for fruit and vegetables; Mr. Godfrey, for asparagus; and to Mr. Lawrence, for asparagus.

New Orchids.

The Orchid Committee awarded first-class certificates to Messrs. Hugh Low and Co., Enfield, for Cattleya Mendeli Oakes Ames and Dendrobium Dalhouseanum salmonea; to Messrs. Linden and Co., Brussels, for Odontoglossum Rodyanum and O. venustum; to Mr. Charles Vuylsteke, Loochristi, for Odontoglossum crispum-Harryanum; to Messrs. Charlesworth, Bradford, for Lælio-Cattleya Admiral Dewey and Cattleya Fernand Devis.

Awards of merit to W. P. Burkinshaw, Esq., Hull, for Cattleya Mendeli Amelia; to M. Jules Hye Leyson, 117, Coupure, Gand, for Miltonia Bleuana rosea gigantea; to Messrs. Hugh Low, Enfield, for Cattleya Mendeli Mrs. E. V. Low; to Messrs. Linden and Co., Brussels, for Odontoglossum crispum zebrinum O. decorum, and O. Pescatorei bellatulum; to Messrs. Charlesworth and Co., for Lælio-Cattleya intermedia Flava; to Mons. A. Madoux, Anderghen, for Odontoglossum Charlesianum; and to Messrs. J. Backhouse and Son, York, for Miltonia vexillaria Empress Victoria Augusta.

New Plants and Flowers.

First-class certificates were awarded by the Floral Committee to Phlebodium glaucum Mayi, from Mr. H. B. May, Edmonton; to Acalypha Sanderi and Licuala Jeanenceyi, from Messrs. F. Sander and Co., St. Albans; and to Lilium rubellum, from Messrs. R. Wallace, Colchester.

Awards of merit were made to Holly Golden King, from Messrs. Little and Ballantyne, Carlisle; to Auricula Snowdrop, from Mr. R. Dean, Ealing; to Begonia Mrs. Dunbar Wood, from Mr. T. S. Ware, Tottenham; to Phyllocactus Epirus and P. Agatha, from Messrs. J. Veitch and Sons, Chelsea; to Caladium Ami Schwartz and C. Ibsenianni, from Messrs. F. Sander and Co.; to Eremurus robustus Elwesianus, from Mr. T. S. Ware and Mr. Prichard; to Caladium Guaratinguetor, from Messrs. J. Laing and Sons; to H.T. Rose Aurora, from Messrs. W. Paul and Son, Waltham Cross; to Tree Pæonies Julius Cæsar, Jean de Reszka, and Henry Irving, from Messrs. Kelway and Son, Langport; and to Anthurium Scherzerianum Senateur Montefiore Levis, from Mr. L. de Smet-Duvivier, Grand Belgique.

The space available will not admit of our doing full justice to the whole of the contributions to this great gathering in the current issue, and we shall consequently deal with the remaining sections and describe the new plants in our next.

WEST'S
PATENT
IVORINE
PLANT LABELS
NAME TO BE WRITTEN ON WITH ORDINARY LEAD PENCIL OR PEN AND INK.

THE "IVORINE" WRITING DISC

Being made of a specially prepared substance, having the properties of real ivory, is imperishable, and does not corrode or eat away, like wood and metal labels; and being ivory white, when written upon it shows to perfection. And also, as the writing is on the Ivorine itself it is permanent, hough washable, and dces not become unreadable, as is the case with all painted labels, as the paint gets old. It is for all purposes, and will last a century, either in a greenhouse cr out in a garden, and t only is it always ready for use, and may be written on both ies, but the name when written in pencil may be easily rubbed ff, and so used as many times as desired.

PRACTICAL LANDSCAPE GARDENING and ESTATE DEVELOPMENT CO.

This Company undertakes to advise as to the laying out of gardens, the general improvement of landed property, and the development of building estates; to provide plans and estimates, and, for a fixed sum, to carry out all work incidental to the making of the smallest Villa garden as well as to the designing and execution of the most extended estate improvements.

It has a staff of experienced foremen, and all necessary plant.

No charge whatever is made for plans, which, however, remain the property of the Company unless the work is carried out by it.

All communications to be addressed to—

THREE INSERTIONS FOR THE PRICE OF TWO!

BARR and SONS have on their Register several competent HEAD GARDENERS. They will be pleased to furnish full particulars on application.—12 and 13, King Street, Covent Garden, London.

FOREMAN or Journeyman. First in good establishment; three years in gardens here and two Kedleston; first class references as to character and ability; age 22.—F. SADLER, Allestree, Derby.

GARDENER (Head or good Single-handed), with help, well up in management of fruit trees, seakale, tomatos, mushrooms, cucumbers, kitchen garden, pleasure grounds, flowers, land, stock, poultry if required; 15 years' excellent character present place; leaving through employer's death; married; middle age.—J. SANSOM, Barcate Cottage, Faringdon, Berks.

FOREMAN, Inside; age 29.—Mr. Osborne, Grove Gardens, Teddington, Middlesex, can thoroughly recommend his Foreman. Well up in Plant Growing, Early and Late Forcing, Fruit, Melons, Cucumbers, Orchids, &c. Near London preferred.

GARDENER (Head), where two or three are kept; age 33; married, no family.—Rev. G HENSLOW, Drayton House, Ealing, W., will be pleased to RECOMMEND E. Pest as above; 17 years' experience; Inside and Out.

GARDENER (Head or good Single-handed); 13 years' experience inside and out; capable and trustworthy; single.—A. M., 11, Bertram Cottages, Hartfield Road, Wimbledon.

GARDENER (Head Working or good Single-handed); age 28; single; thoroughly experienced in kitchen, fruit, and flower garden, lawns, &c., little glass; thirteen years' good character; abstainer.—PRITCHARD, Low Farm, Wellesbourne, Warwick.

GARDENER (Head Working); where two or three are kept; 16 years' experience; age 30. Mr. W. A. Miller will be very pleased to RECOMMEND his foreman as above.—S. PEET, Underley Gardens, Kirkby Lonsdale.

GARDENER (Head Working), age 30; thoroughly practical in the general routine of gardening; experience gained in first-class establishments; 3½ years Foreman in present place; can be well recommended.—W. CONWAY, Minley Manor Gardens, Farnboro', Hants.

GARDENER (Head or good single-handed); 12 years' experience in all branches; age 24; single; excellent characters from past and present situations.—Apply J. W., Covers Road, Claygate, Surrey.

GARDENER (Head) where three or four are kept; life experience in all branches; age 40; married, two children; good references.—Address J. DENTON, Up Down Hill, Windlesham, Surrey.

GARDENER (Good Single Handed, or with help); 15 years' experience on vines, tomatos, chrysanthemums, &c.; kitchen and flower garden; married; age 31; one child; good character; abstainer.—W. MARTIN, 5, Langroyd Road, Upper Tooting, S.W.

GARDENER (Good Single-handed, or with help); life experience both inside and out; three years in last place; age 29.—W. P., 48, Lewisham Road, S.E.

GARDENER (Single-handed or under); 8 years' good character; married when suited.—F. BALL, Long Cross, Chertsey.

GARDENER (Under or Second); 8 years' experience; 4½ years' good character; abstainer; age 20; single.—WHITE, 56, Branksome Road, Acre Lane, Brixton, S.W.

GARDENER (Under); age 20; four years' experience, Inside and Out. Inside preferred. Well recommended.—E. WOTTON, Greenham, near Wellington, Somerset.

JOURNEYMAN (First).—C. Goldsmith, 32, Danvers Road, Tonbridge (late Leonardslee, Horsham), is open to an ENGAGEMENT as such; thorough knowledge of fruit houses; life experience; age 25; abstainer.

JOURNEYMAN; Age 20; SEEKS SITUATION; Inside; seven years' experience; three years present place; good character.—H. MULLINS, Rushmore Gardens, Salisbury, Wilts.

To Nurserymen and Gentlemen's Gardeners.

PAINTER and GLAZIER.—Understands greenhouses, handy at repairs, wants estate work; or a small job not objected to; own tools; any district; references; disengaged Tuesday next.—G., 62, Gloucester Road, Croydon.

RICHARD SMITH and CO., beg to announce that they are constantly receiving application from Gardeners seeking Situations, and that they will be able to supply any Lady or Gentleman with particulars, &c.—St. John's Nurseries, Worcester.

TO HEAD GARDENERS.—Young Man age 25, SEEKS SITUATION in kitchen garden and pleasure grounds; 8 years' good experience; good reference.—Apply J. EDMONDS, Heath View, Worplesdon, Guildford, Surrey.

UNDER-GARDENER SEEKS SITUATION as Second, or with Foreman under glass; age 22; four and a half years' inside and out; best references.—State wages, &c., to A. MAYNARD, Roseneath, Muswell Hill Road, Highgate, N.

WANTED SITUATION as GARDENER Single Handed; six years in present situation, leaving through death; age 29; married; one child; abstainer; highest references.—G. S., Stables, Homefield, Bickley, Kent.

YOUNG MAN SEEKS SITUATION in Garden; 9 years' experience; Inside and Out; well recommended.—A. WHITE, Littlebourne, near Dover.

YOUNG MAN, aged 20, SEEKS SITUATION as Under Gardener, inside and out; four years' experience; good references.—W.D., The Limes, Church Street, Bishop Stortford, Herts.

YOUNG MAN, having about £40, WISHES to JOIN with another in NURSERY, &c.; had some experience.—Particulars of ROWED, Jun., Kingsfield, Woking.

YOUNG LAD, 19 years, SEEKS SITUATION as Improver; three years' excellent character; inside preferred.—T. X., 32, Queen Street, Wolverton Road, Stony Stratford.

Situations Vacant.

Advertisements under this heading are charged 2s. 6d. for Four lines (32 words), and 6d. per line of eight words after.

WANTED, a willing MAN as Jobbing Gardener, to go out by himself to work; temperance man preferred; £1 or 21s. per week; overtime paid; state age; constant place.—G. WHEELER, Brook Green Nursery, Hammersmith.

WANTED.—OUTDOOR FOREMAN for Bedding Begonias, Carnations, General Herbaceous Stuff. Also several General Nursery hands; permanent situations for good men.—H. J. JONES, Ryecroft Nursery, Lewisham.

WANTED, a young MAN, for Small Nursery, principally glass. Must understand growing Chrysanthemums for exhibition; permanent situation for a suitable man.—Apply J. W. SIMMONS, Duester, Spratt Hall Road, Wanstead, Essex.

FOLLOWS & BATE, LIMITED,
GORTON,
MANCHESTER.

FOR WEEDY LAWNS,
TENNIS COURTS, &c.,
USE THE

PATENT
"WIKEHAM"
WEED ERADICATOR.

An instrument for applying Weed Killer to Lawns, Flower Beds, &c., for destroying weeds without injury to the surrounding grass or flowers. It is so arranged that by simply stabbing the point into the plant, enough liquid is introduced into the sap to destroy it.

When not in use the point is protected by a cover which can be screwed on or off as desired, and in this way may be safely carried about like an ordinary walking stick. It cannot become clogged with earth, and has been acknowledged by all who have used it to be the simplest and best invention that could be brought out for the purpose.

Price 8/- each. Postage, 4d.

"CLIMAX" WEED KILLER

Will keep your Drives, Paths, Promenades, and Stonework bright and free from all vegetation for a whole season, by ONE APPLICATION.

HAS NO SMELL. Can be applied with any ordinary watering can.

It SAVES 100 per cent. in the COST of LABOUR.

NOTE.—It is double the strength of other preparations, 1 gallon makes **51** gallons for use.

MIDDLETON, MANCHESTER.

Fir Tree Oil INSECTICIDE

For destroying Insects on Plants. Used by every Orchid Grower of any note all over the world.

The CHEAPEST and BEST.

Half pints 1/6, pints 2/6, quarts 4/6, half gallons 7/6, gallons 12/6, 5 gallon drums 10/6 per gallon Carriage Paid.

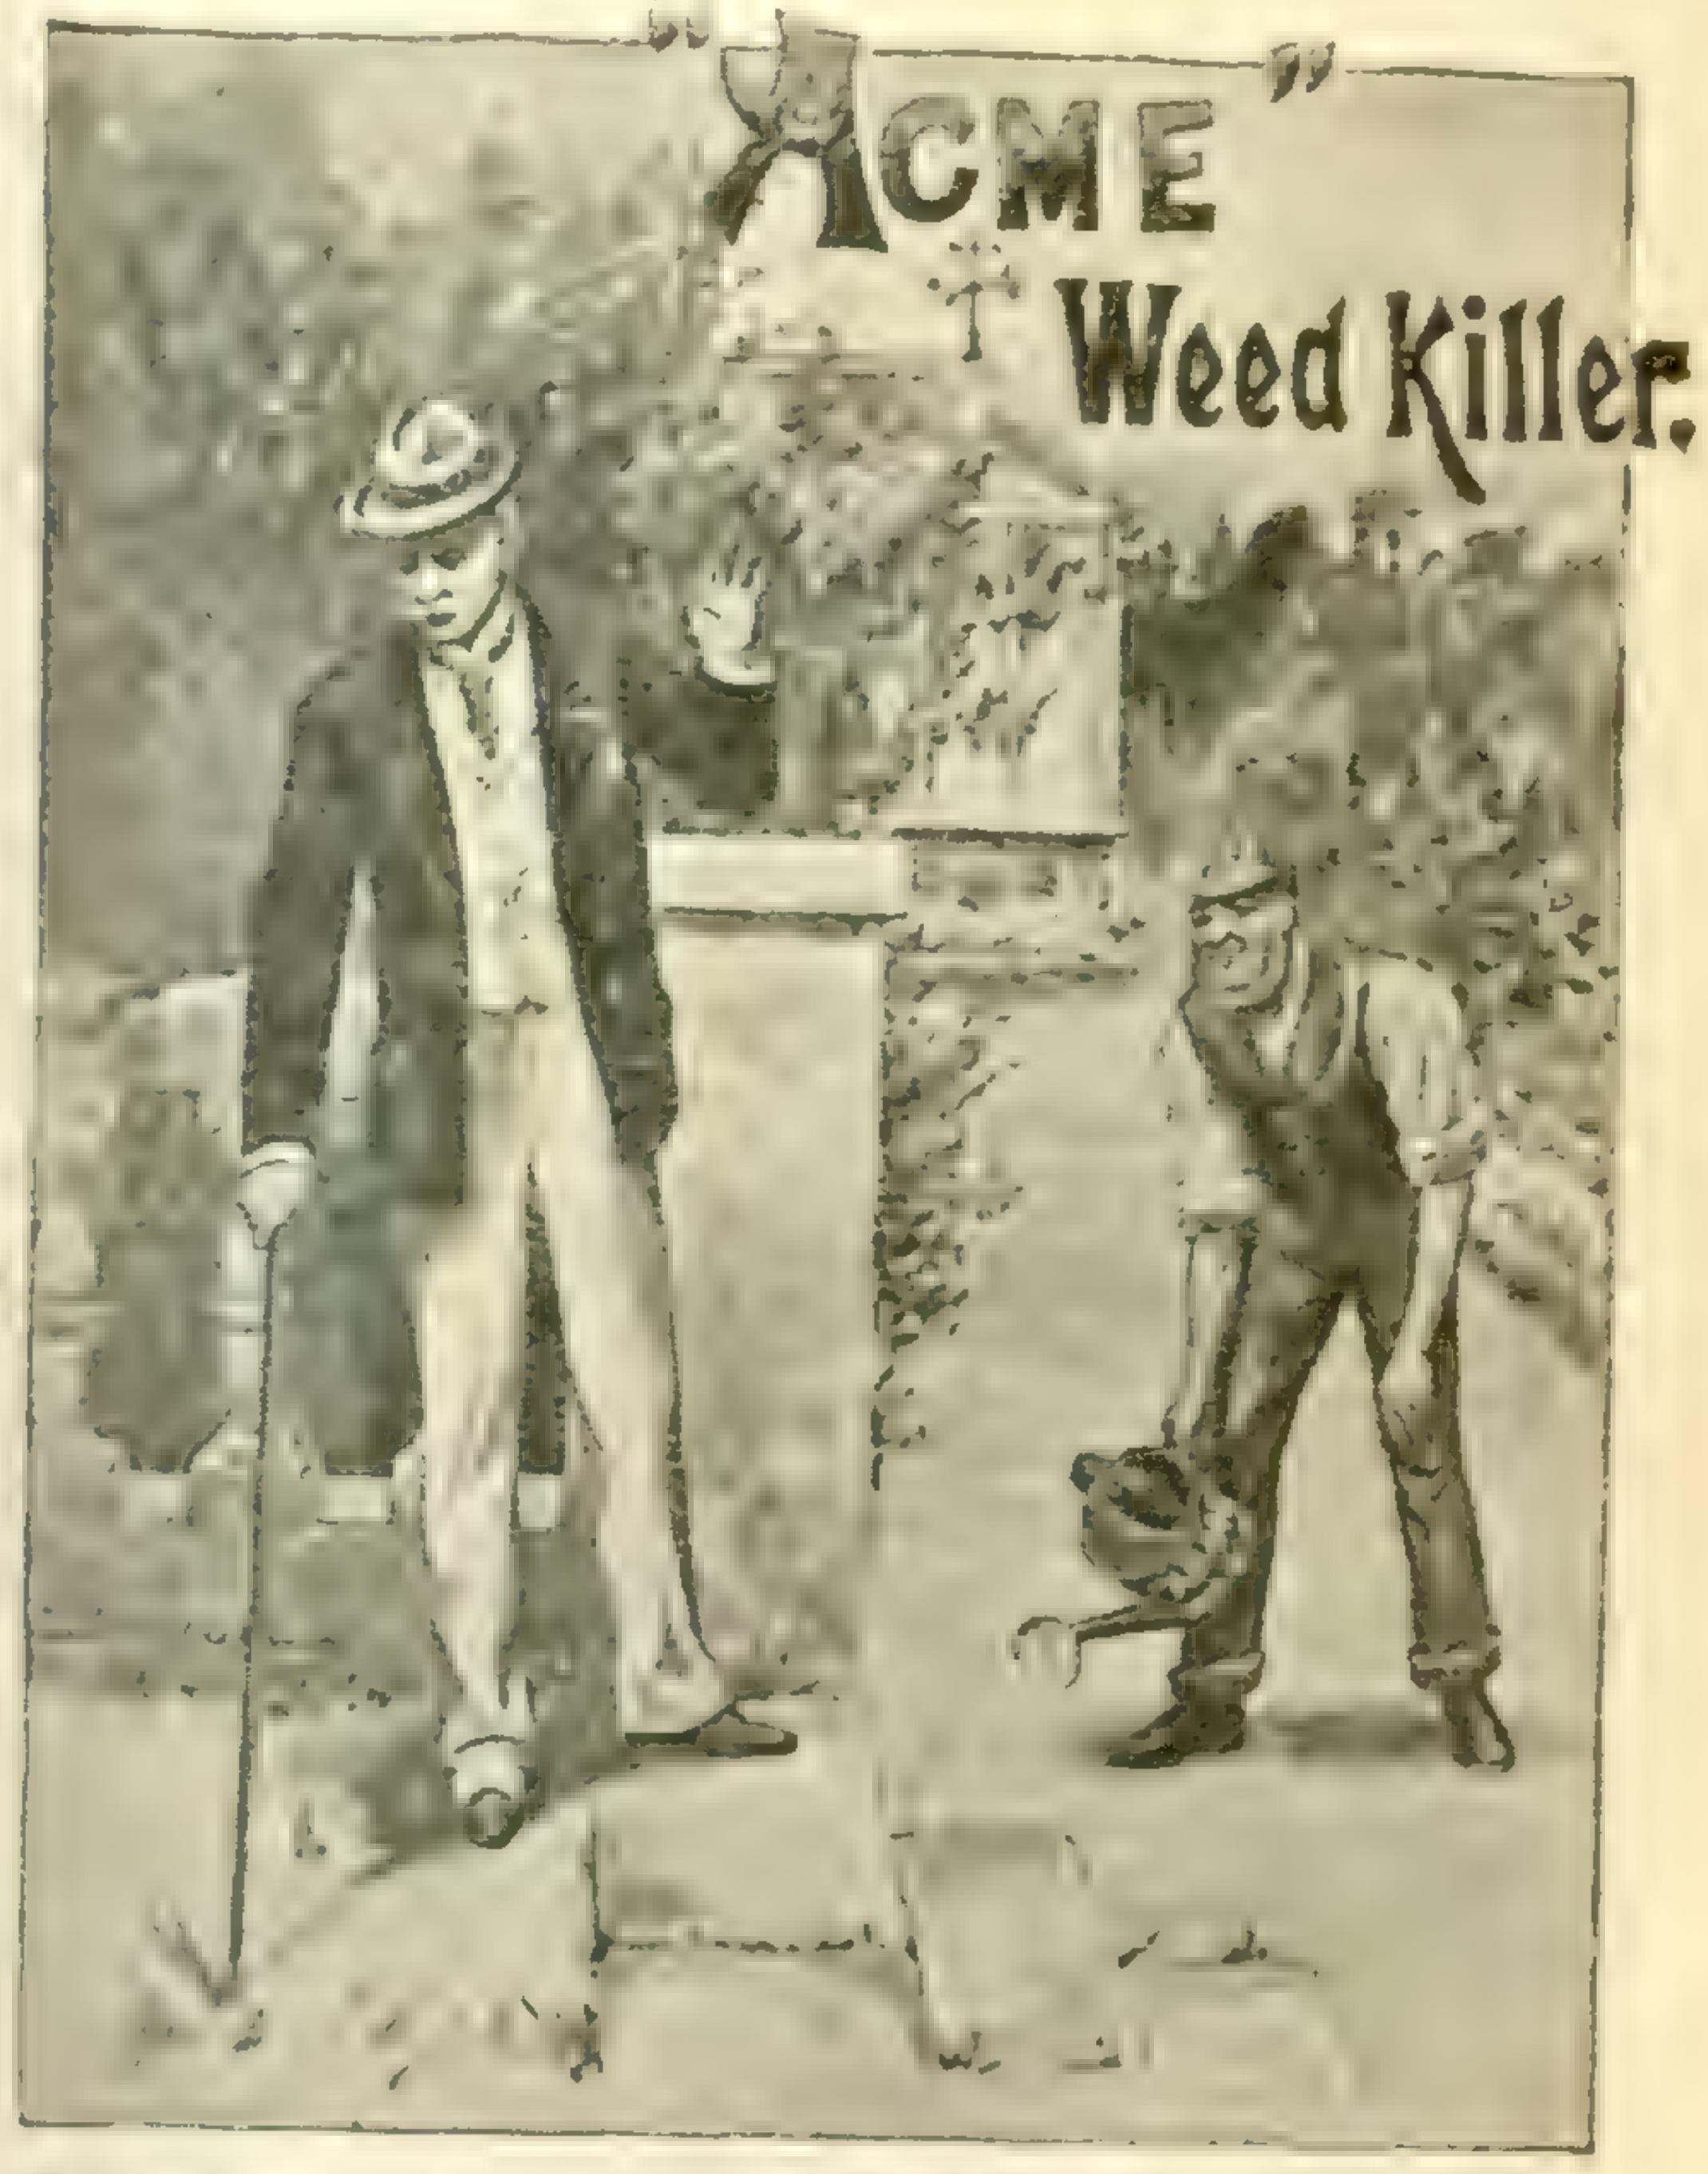
E. G. HUGHES, VICTORIA STREET, MANCHESTER.
Sold by all Seedsmen. *Pamphlets free on application*

EPPS'S COCOAINE.

COCOA-NIB EXTRACT.

The choicest roasted nibs (broken-up beans) of the natural Cocoa on being subjected to powerful hydraulic pressure, give forth their excess of oil, leaving for use a finely-flavoured powder—"Cocoaine," a product which, when prepared with boiling water, has the consistence of tea, of which it is now, with many, beneficially taking the place. Its active principle being a gentle nerve stimulant, supplies the needed energy without unduly exciting the system. Sold only in labelled Tins. If unable to obtain it of your tradesman, a tin will be sent post free for 9 stamps.

JAMES EPPS AND CO., LTD.
Homœopathic Chemists, London.



"Weeds, weeds, everywhere. I wonder if that new gardener can suggest anything."

"Yes, Sir, I'm just using the 'Acme' Weed Killer. The best thing in the world for killing weeds."

Used in the Crystal Palace Grounds,
The Royal Horticultural Society's Gardens,
AND IN THE
Principal Gardens of the United Kingdom.

NEW ROSES

AURORA

(Hybrid Tea), flowers rich bright salmon pink in centre, shading paler towards the outside, large, full, and imbricated, handsome buds. Extra fragrant, and produced continuously in great profusion. Award of Merit at the Temple Flower Show, May 25, 1898. Good plants now ready, **10s. 6d.** each.

M. ADA CARMODY

(Tea Scented), ivory white, beautifully tinted and edged with various shades of pink, centre tinged with yellow; large and full, with fine long buds; growth moderate. **10s. 6d.** each.

EMPRESS ALEXANDRA OF RUSSIA

(Tea Scented), outdoor flowers rich lake-red, shaded with orange and fiery crimson; under glass the colours are paler, rosy buff and salmon. Award of Merit R.H.S. **3s. 6d.** and **5s** each.

WALTHAM STANDARD

Hybrid Perpetual), brilliant carmine, shaded with scarlet and violet, shape and petal of **A. K. Williams.** **3s. 6d.** each.

ENCHANTRESS

(Tea Scented), creamy white tinted with buff, of extraordinary freedom in blooming, and one of the most lovely and effective new roses. Award of Merit and Silver Banksian Medal. **2s. 6d.** each; **24s.** per dozen.

QUEEN MAB

(China), a charming decorative and button-hole rose, producing large quantities of finely formed buds; colour soft rosy-apricot, shaded with orange, and tinted with rose. Award and Certificate of Merit. **2s.** and **2s. 6d.** each; **18s.** per dozen.

A selection of the best new **ENGLISH** and **CONTINENTAL ROSES** of 1897 and 1898, **24s.** and **42s.** per dozen.

Priced Descriptive Catalogue post free on application.

E. V. MATTHEWS, 33, St. John's Road, Ryde.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at One Shilling per line, the minimum charge being Five Shillings. Advertisement Office, 148 and 149, Aldersgate Street, London, E.C.

LOST.—At the TEMPLE SHOW, the ORCHIDS EXHIBITED by M. JULES HYE, of GHENT, BELGIUM, disappeared from the tent on the evening of the last day of the Show.

Any person giving such information to Messrs. JAS. VEITCH and SONS, LIMITED, Chelsea, as will lead to their recovery will be handsomely REWARDED.

NOTICE TO ADVERTISERS.

Owing to the continued increase in circulation, the "Gardeners' Magazine" now goes to press on Wednesday. No advertisement can be guaranteed insertion, or altered, unless received before Four p.m. on that day.

NOTES OF THE WEEK.

DISCOMFORTS OF FLOWER SHOWS.

FLOWER shows on a large scale have been held in the United Kingdom for nearly seventy years, and during this long period they have, as the result of changes in public taste, varied materially in their distinguishing characteristics. Specimen hard-wooded plants from the Cape and Australia, which constituted the chief attractions of the earlier exhibitions, were followed by plants remarkable for the beauty of their leafage; these had to make way, to a considerable extent, for soft-wooded plants; and now the chief features of these gatherings are orchids, hardy plants, and mixed collections. Throughout the seven decades there has been a continuous change in the predominating features, but in methods of procedure there has been so little deviation from the lines originally laid down that some justification might be found for those who regard the laws governing horticultural gatherings as analagous to those of the Medes and Persians. Flower shows possess at the present time attractions and discomforts about equal to those which characterised summer exhibitions held half-a-century ago, and few problems associated with horticulture appear more perplexing than the continuance of the practices which obtained favour with the past generation of flower show managers. Improvements in matters of detail have in a few instances been made; but there is unmistakable evidence on all sides during the summer season of a want of appreciation of the comfort of visitors, and the most conclusive proofs of the truth of this assertion are to be found in stuffy tents, insufficient seating accommodation, and indifferent or extravagantly-priced refreshments. To those in a robust state of health a walk through several tents crowded with visitors, without a single aperture excepting the opening at each end, may not be attended with any serious consequences; but in the case of ladies with constitutions other than strong, the stifling atmosphere imposes a severe strain upon them, and may affect their health for several days. In the same way, while men engaged in outdoor operations and constantly walking about are not appreciably fatigued by standing about chatting to their friends, the majority of ladies find it very trying to stand for any length of time. Such matters as these should be known to all who assume the responsibilities of carrying out the details of a horticultural exhibition, and there should be no occasion for complaint either of a stifling atmosphere or of an insufficient number of chairs. Ventilation is not less necessary in tents than in rooms, and yet it is a quite common occurrence to find the most careful precautions taken to prevent any change of the atmosphere within them. No tents should be regarded as suitable for use at a flower show that is not provided with ventilators near the apex, and these should be supplemented by openings for the admission of air at the sides. Care is, of course, necessary in regulating the ventilation of tents, and this important detail should be placed under the charge of some one who is equal to the task of admitting sufficient air to maintain a pure atmosphere without exposing plants or visitors to cold draughts or the tents to the risk of injury from gales of wind. Generally speaking, chairs should be provided in larger numbers than appears to be considered necessary by committees, and in many instances some reform should be effected in the supply of refreshments, both in the matter of quality and price. To state the case briefly, some endeavour should be made to remove the discomforts of flower shows, for it is only by making these functions enjoyable as well as interesting that they will continue to receive the support of the general public.

ORCHIDS.

THE grand exhibition of orchids at the Temple, though mainly striking on account of the splendour of the flowers, had a deep stratum of underlying interest in the curious correlation of abundant bloom with apparently a minimum of root nourishment. With most other plants good soil and abundant feeding at the roots appear to be absolutely essential to a free production of blossom, but here we find an apparently dry bit of corkback, or a bundle of sticks wired together round a handful of moss, and therefrom will be depending rich, solid-looking waxen blooms of Cattleya citrina or other species, obviously in the very perfection of health, though all they possess as feeders are a few thick fleshy cords, which hardly answer to the popular idea of roots at all. Then, again, with most plants we look for a fair share of foliage to serve as aerial feeders of the flowers, but here, again, we are confronted with a lot of dry-looking pseudo-bulbs, with here and there a coarse leathery-looking leaf sticking out of them, and from this unpromising-looking mass rises a rampant spray of scores of delicate floral butterflies, as great a contrast as butterflies proper to the uncouth-looking chrysalis from which they emerge. Another point which strikes the outsider is the marvellous diversity of the tribe, ranging from huge spreading yard-long sprays of Cymbidium Loweanum down to tiny dots of plants which almost require a microscope to determine if they be orchids at all, though their names are long enough to read without any aid whatever, save that of a pronouncing dictionary and a pliable tongue. Some flowers, as in the dendrobiums, hang in dense bunches like etherialised laburnum blooms, while others, like the masdevallias, present as striking a contrast as can be conceived within one family of plants by their solitary and brilliant spiky-looking inflorescence. It is, indeed, only when we come to the cypripedium tribe that we begin to feel at home with orchids; these, at any rate, have a sensible home-like habit of growing upright from soil proper, and in addition we find pretty foliage in fair proportion to the bloom; but once again the eccentricity of the orchid tribe takes us by storm when we find these otherwise reasonable members, not content with putting on all sorts of bizarre stripes, spots, and other markings, have absolutely run mad in the moustache line, and after soaring up from the ground for a foot and more, drop the pendulous tips of their moustache aforesaid all the way back again, for what earthly purpose save orchidaceous and audacious dandyism it is impossible to conceive. Natural selection has certainly been at work, but it is just as certainly a puzzle to determine whose the selection has been which decks a lady's slipper with such a peculiarly masculine adornment. While we are thinking of these things, however, our side-eye has been caught by a group of cattleyas, and lælio-cattleyas, in their simple or compound forms, and turning a full glance upon them, we forget all about the oddities in question, and become utterly absorbed in, and entranced by, the wondrous beauty herein evidenced, and reflecting that the grand originals must owe their charms entirely to the appreciative selection of those insects for whose visits as love messengers their beauty has been shaped, we pass on with the verdict that mankind can by no means claim a monopoly of good taste in this wonderful world of ours.

COMMERCIAL ASPARAGUS CULTURE.

THE immense supplies of asparagus that have for some time past been pouring into British markets from Toulouse, the neighbourhood of Paris, and other parts of the Continent of Europe, suggests to us the desirability of cultivators considering whether a considerable proportion of the produce which finds a ready sale in our markets might not be grown at home with advantage to all concerned. The asparagus is indigenous to this country, and if proof were wanting of its adaptability to the climatic and other conditions that obtain in the United Kingdom, we could point to many gardens where the produce of the asparagus is fully equal to the best that is obtained from abroad. There can be no question as to the possibility of our supplying the markets with asparagus equal to the finest of the foreign supplies, and if we fail to do this, a cause other than an unfavourable climate or an unsuitable soil must be sought for. It is evident from observations made in widely separated districts that the possibilities of the commercial culture of asparagus in Great Britain is not fully appreciated by the general body of cultivators. Were it otherwise, the area devoted to the vegetable would be speedily increased tenfold. Asparagus has a great advantage over the majority of vegetables grown for market, inasmuch as its value is much greater in proportion to its bulk, and can therefore be sent long distances at a relatively small cost. Consequently it is specially adapted for cultivation in districts where, owing to the distance from the markets, the more bulky vegetables cannot be profitably grown, a fact which cultivators in remote districts ought not to overlook. In suggesting the desirability of largely extending the culture of asparagus for market, we must not be understood as recommending it as a crop adapted for all soils and situations, and to prevent any misapprehension upon this point we distinctly state that its culture for market should be commenced only where the soil can at a small cost be prepared for the formation of plantations. Rich alluvial soils, such as are to be found in many of our valleys, are the best for asparagus, but any moderately deep and naturally rich, well drained loam will be found suitable, as no heavy outlay will be involved in its preparation, or in maintaining it in a fertile condition. An admirable object lesson in asparagus culture is given by the growers in the Evesham district. A quarter of a century ago some of the market gardeners began to plant asparagus, and finding that under a liberal system of cultivation produce of the highest class was obtained, they made themselves familiar with the best method of marketing, and, as the result, obtained good prices. The asparagus crop has, indeed, been found so profitable in this fertile valley that there has been a continuous extension of the area, and at the present time it is estimated that there are upwards of four thousand acres under asparagus, giving an annual yield of sixteen thousand bundles. What has been accomplished at Evesham should be attempted in other districts where similar conditions obtain, for the demand for fresh gathered produce of high quality is so great that the supplies must be enormously increased before they can seriously affect prices.

Castle Ashby.—With the current issue of the GARDENERS' MAGAZINE is presented a special supplement containing an illustrated account of Castle Ashby and its gardens, and a separate two-page plate of the mansion.

M. Jules Hye's Orchids.—We greatly regret to learn that the very valuable orchids exhibited by M. Jules Hye, of Ghent, at the Temple Show, disappeared on the closing day of the exhibition, and so far no trace can be ascertained of their whereabouts. They were seen by their owner soon after nine p.m. on the Friday, but an hour later they had been removed from the position they had occupied, and he is naturally much distressed at having lost them. The loss of such valuable orchids as these is a very serious matter, and we trust that if they were removed by mistake they will be at once returned, and that if they have been stolen they will be speedily recovered. Messrs. J. Veitch and Sons (Limited) inform us that any person giving such information to them as will lead to the recovery of the orchids will be handsomely rewarded.

The Beauties of the Thames Valley can scarcely be overrated at this season of the year, though, unfortunately, the chilly winds that prevail, and the prospect of frequently recurring storms, render a full appreciation of hill and valley, water and island, trees and flowers, impossible at present. Given an hour or two of fine weather, however, a walk from Kew Bridge to Richmond along the riverside provides a treat for anyone, and especially for those who spend much time in the City. The fragrance and beauty of the hundreds of white thorn rees along the towing-path alone compensate for the time occupied in the walk, but added to these there are golden cascades formed by the laburnum, bending by reason of the weight of blossoms over the boundary wall of the Royal Gardens. The stately chestnuts are grand pictures, their myriads of erect panicles standing out in bold relief against the background of ample foliage; rhododendrons in the gardens and the Queen's Cottage ground add to the general beauty, while one cannot but admire the breadths of elegant white-flowered umbellifers that skirt the margin of the moat and the Old Deer Park. To the beauty of the flowers all around must be added the beauty of form in the trees from the slender willow, the towering poplar, and the massive horse-chestnut to the stately elms, elegant ash trees, gnarled oaks, and quivering birches; neither can one omit to note the charming tints of the leaves from the beautiful green of the young oak leaves to the more sombre hue of pine and yew.

A Chrysanthemum Congress at Lille will be held on November 10, when the following subjects will be discussed: (1) The soils and manures most suitable for chrysanthemums; (2) The best insecticides and fungicides for chrysanthemums; (3) Influence of climate on varieties; (4) Dimorphism of he chrysanthemum and the causes producing sports.

Floriculture at Nice.—The decision of the English Post Office authorities no longer to admit cut flowers from abroad by sample post has caused a good deal of apprehension on the part of the Riviera flower growers. Even Consul Sir J. C. Harris, in his report for 1897-8, says that however justified the decision may be by the abuse which appears to have been made of the privilege, it is certain to be very harmful to the export trade in flowers, to which so large an extension has been given in the Nice district of late years by the much increased facilities of irrigation. In order to give an idea of the large place flower culture has attained to in these days when the keiroun insect has ravaged olive yards and rendered them unproductive, and the phylloxera has equally damaged the vineyards, he states that at the recent meeting of the agricultural society the only subject treated of by successive speakers was the horticultural exhibition which has lately taken place at Nice, and which, indeed, deserved all the praise bestowed upon it. The Consul perceives, however, a tendency to utilise the built-up terraces not only for the growth of flowers, but also for fruit trees, which in a country of prolonged summer droughts require a considerable amount of irrigation. The two crops should do well together so long as the fruit trees are not allowed to grow so large as to interfere by means of their spreading roots with the annual flower culture, for it should be remembered that the flowers bloom in the winter and early spring, when the fruit trees have no foliage, and that the flower plants are allowed to die down in the summer, when the water, which is available all the year round can be used for the benefit of the fruit trees.

Mr. Jurgens, the distinguished landscape gardener of Hamburgh, who was responsible for the preparations of the grounds for the great exhibition held in that city last year, has received the order of Merite Agricole. Mr. Jurgens not only laid out the grounds, but by his geniality and ready advice contributed in no small degree to the pleasure of English horticulturists who visited Hamburgh during the time the exhibition was open.

Exceptional Rainfalls.—Notwithstanding the heavy rainfall of the past few days, it is of interest to mention in this connection that the average of the rainfall registered at thirty-three of the principal towns in England during the week ending May 28 was only 0·57 inches. We have not by any means had an exceptional fall. So far as annual rainfall is concerned the Khasia Hills lead the way with 600 inches; Padupola, in the central province of Ceylon, has a mean average rainfall of 230·85 inches; while in the northern province, at Nedunkeni, the average fall is 64·70 inches, though the total for 1897 was 121·85 inches. A correspondent to *Nature* points out that at Nedunkeni there was an exceptionally heavy rainfall on December 15-16, 1897, when in twenty-four hours 31·76 inches was registered. It will be interesting to point out here that the highest rainfalls previously recorded were at Joyeuse, France, 31·17 inches in twenty-two hours; at Genoa, 30·00 inches in twenty-six hours; at Gibraltar, 33 00 inches in twenty-six hours; on the hills above Bombay, 24·00 inches in one night; and on the Khasia Hills, India, 30·00 inches on each of five successive days.

The Artificial Colouring of Cut Flowers is now becoming only a little less general than the provision of odour, by means of essences, for flowers that have lost their fragrance while travelling from the producer to the retailer. In this connection "Dogberry," in writing to the *City Press*, remarks that: Spring flowers have been plentiful in the streets and shops of the City during the past few weeks, some of them of extraordinary beauty. Things are, however not always what they seem. A personal friend, attracted recently by the strange appearance of a favourite flower in a shop window, went in to purchase a bunch. While doing so he inquired whether the plants could be obtained, and was obliged to rest satisfied with the assurance that they were an exclusive cultivation. A few days afterwards he made a second purchase, which he handed for inspection to a professional florist. Then he learned the secret—the flowers had been painted, or, rather, "improved" by the application of chemical dyes! Alas, what has not modern chemistry to answer for? A gentleman who occupies a high position as a practical chemist tells me that not a week passes without his receiving an application for a dye to make something or other look like something else; but I did not know that the art of "sophistication" had been carried quite so far as it appears it has. I have heard of flowers being artificially scented, but the staining of them will not, I hope, become a common practice.

The First Rose of Summer.—In a postscript to a letter written on June 1, that genial rosarian, the Rev. A Foster-Melliar, writes: My daughter, gathering the first outdoor rose to-day in this very cold wind, suggested, June 1st:

> "'Tis the First Rose of Summer,
> I heard it complain—
> You have waked me too soon,
> I must slumber again."

The Cultivation of the Date Palm (*Phœnix dactylifera*) has steadily increased in the Turkish-Arabian province of Bussorah since the packing of dates in boxes for export to the United Kingdom and America was started about fifteen years ago. Consul L. A. Forbes states that in 1896 the greater part of the country was inundated by unprecedented floods, in which it is reported over a million date palms were destroyed; these trees, it is believed, have been all replaced by young ones, but still it will take six to ten years before the latter produce fruit in any quantity. The high prices which are now obtained by the growers for their dates have rendered the possession of date gardens most valuable property, and the culture of the date palm receives from the Arabs great care, attention, and expenditure of capital in manuring and irrigation, which is not the case with land under any other form of produce. Vinegar is manufactured from dates, and it is probable that whisky could be made from them, as "arak," the native spirit, is distilled exclusively from dates.

Gardeners' Royal Benevolent Institution.—We have to remind our readers that the fifty-ninth anniversary festival dinner of this institution will be held on Wednesday next at the Hotel Metropole. We trust that the Duke of Portland, who presides, will be well supported, and, having regard to the heavy claims upon this excellent charity, we hope the subscription list on this occasion will be a liberal one. The Dean of Rochester has promised to be present, and those of our readers who desire to attend should communicate with the secretary (Mr. G. J. Ingram), at 50, Parliament Street, S.W.

Mr. J. Gray, late of Bodorgan Gardens, Anglesea, was the recipient of a set of handsome carvers subscribed for by the under gardeners before leaving the service of Sir George Meyrick, Bart. It is over twelve years since Mr. Gray took charge of these gardens, during which time he has much improved them and kept them up in a high state of efficiency. General regret was expressed by Mr. Gray's friends when he decided to leave the neighbourhood.

Mr. Ernest Bergman, secretary of the National Horticultural Society of France, received on the occasion of the society's recent exhibition at Paris, the decoration of an Officer of Public Institution.

Flowers for Schools.—At the meeting of the London School Board, the School Management Committee reported that they had had their attention called to the following report from the British Embassy at Berlin, giving the arrangements made in Berlin for supplying primary schools with flowers from the public parks: "In the town gardens here (Berlin), and especially in 'Humboldt-Hain,' flowers are gathered in proportionate quantities during the summer months of the year, and are placed at the disposal of the upper grade and lower grade municipal schools, at their desire, and also at the disposal of private schools for a consideration, for the purpose of furthering the study of botany. The flowers are sent to the schools in especially ordered carts twice a week; they are sent in bundles, each bundle containing fifty specimens of the same species of plant, and only one bundle falls to each botany class. The names of the plants which may be expected during the week are published every Sunday in the public Press. Flowers from the town gardens are not supplied for the decoration of schools, or making presents of them to scholars." The committee were of opinion that similar arrangements might possibly be made in London, and with a view of achieving that object recommended that letters be addressed to the London County Council and to her Majesty's Office of Works, setting forth the arrangements which were now made in Berlin for supplying flowers from the public parks to the elementary schools, and inquiring whether somewhat similar arrangemenss could not be made for the benefit of public elementary and other schools in London. On the motion of Mr. Graham Wallas it was decided that letters be addressed to the London County Council and to her Majesty's Office of Works with reference to supplying flowers to the London schools in the same manner as in Berlin.

Mr. W. Howard, for many years manager to Messrs. J. Veitch and Sons, at their Coombe Wood Nurseries, has now entered upon similar duties with Mr. Anthony Waterer, Knap Hill, Woking. A large number of Mr. Howard's friends at Kingston took advantage of the opportunity his removal from Coombe afforded to present him some tangible token of their good wishes. The presentation was made a few days ago by Mr. A. W. Homersham, J.P., and consisted of a fine gold keyless hunting watch and a purse of ten guineas.

Beauty in Plants and Flowers.—Plant beauty is of two sorts, beauty of colour and beauty of form. In some plants, like the calla, beauty of form predominates; in others, like the pæony, beauty of colour; in still others, like the gladiolus, the lines of stalk, flower, and bud are as noticeably lovely as their colours. In the rose we have beauty both of form and colour. There are different kinds of love for flowers, adds Mr. Henry T. Bailey, of Scituate, Mass., U.S.A. There is the scientific love; those who have only this seldom get the true message of the flowers. At the other extreme are people having a sentimental love for flowers; they pronounce their colours marvellous, and gush indiscriminately over their beauty. The third kind of love for flowers has a basis of intelligent appreciation. The greatest enjoyment is when scientific love is combined with a sympathetic appreciation of beauty.

A New Broom.—Writing to the *Pall Mall Gazette*, Sir Herbert Maxwel says: "Gardeners and garden lovers seem slow to realize the singular beauty of a variety of the common broom which has lately come into the market under the name Cytisus scoparius Andrewsi. In this lovely shrub the standards, or upright petals, are dyed a deep crimson or marone, contrasting vividly with the rest of the golden corolla. It is as easily grown and as hardy as the common type, and may also be forced into bloom a couple of months before it is due to flower in the open. It makes a brave show in the conservatory, and so little are people acquainted with it that visitors almost invariably ask, What is that beautiful exotic?" There is nothing surprising in gardeners and garden lovers failing to realise the beauty of Cytisus scoparius Andrewsi, for no such shrub has "come into the market." The writer is evidently referring to Cytisus scoparius Andreanus, and if this be the case we unhesitatingly say that not only is the beauty of the shrub highly appreciated, but it has already been extensively planted.

Speedy Extraction of Rubber.—At the agricultural exhibition held not long since in Jamaica there was exhibited a new machine for the extraction of rubber from the crude flow of sap. In about two minutes the machine separates the rubber from the milky matter, and is then placed in a suitable place where it will dry in about three hours into sheets or slabs of marketable rubber free from all albumenoid matter. The tree from which the supply was obtained is a species of Castillo.

Progress in Floriculture in America.—For years upon years the progress of floriculture was slow, simply because it was imperfectly understood, and its devotees had hedged it with unbending rules that excluded all but themselves. But a new era of floriculture has dawned. Life is now too short to master even one flower as we have come to understand it. A man deserves to be knighted who takes some sweet floral nymph of the woods, or some old-fashioned favourite of our childhood garden, and make a royal family of it, unlocking the mysterious colours that are hidden in its pale bosom, and turning one modest little cinderella into a hundred queens of beauty and proud grace. In referring to these matters before the Massachusetts Horticultural Society the Rev. W. T. Hutchins, himself an ardent florist and sweet pea raiser, stated that what Mr. Eckford has done for the sweet pea a score of other consecrated noblemen have done for other flowers. The time has not come to canonize these men. They have come through the humble walk of being some rich man's gardener, or they are down on their knees in communion with the soil, wearing the poor man's clothes, earning the pittance of a struggling florist, happy if some lady will pay the cheap price of a nosegay. But if you will believe it they are ushering in the day when floriculture will be the queen of arts, and when men of the proudest ambition and intelligence will aspire to have their names associated in monumental remembrance with the development of some flower. We have carried nothing to perfection yet. One by one the flowers that have great possibilities in them make their advent into this new era. They have only made their graceful bow to us. You have only begun to know a flower when you see it as it is. You must have the prophetic anointing and see it as it is to be.

Ranger's Park, Greenwich, some fifteen acres in extent, was formally opened to the public on Saturday last. The site now covered by flower beds was formerly occupied by Montague House, where the great Duke of Marlborough often resided. This new accession of parkland was cut off from Greenwich Park in 1806 to form a pleasant estate surrounding Ranger's Lodge, a house known at that early date as Chesterfield House. The London County Council are now seriously considering the advisability of acquiring Ranger's Lodge for the purpose of making it available as a shelter to frequenters to Blackheath and neighbourhood.

Rhododendrons and Bamboos are certain to do well in South Devon, consequently these have been employed freely in the work of remodelling and replanting the Northernhay Gardens at Exeter. A piece of land formerly rented by the Northernhay Club has now been added to these public gardens, and so planted as to greatly increase the effect of extent. The new rhododendrons here are now blossoming, and near by is a bamboo garden of small size, but planted with fine specimens of the most beautiful species. On other slopes that formerly were covered almost entirely with laurels and other evergreens, variety has been introduced, and there are now graceful flowering shrubs, as lilacs, syringas, viburnums, thorns, deutzias, weigelas, and hypericums; further along where the common Cytisus scoparius has always done so well, many choice kinds have been planted, such as C. s. Andreanus, C. præcox, C. albus, &c. It is proposed to raise the roof of the band stand, so that during summer it will be possible to suitably decorate the structure with various free growing climbers, and suspended baskets of graceful and bright flowers and plants.

The Double-naming of Florists' Flowers is a matter that often causes much inconvenience in this and other countries, but it is one that is not easily put right unless a central body for deciding which name should be retained was created. The Society of American Florists is making efforts in the right direction, as its Nomenclature Committee intends to lay before the society any cases of misnaming or double-naming of plants handled by the American trade. Such cases will be dealt with, but we are not aware on what lines or how delinquents will be treated. Professor W. Trelease is chairman, so we may feel assured that the question will be thoroughly worked out.

Fatal Effects of Drinking Weed Killer.—It appears almost incredible that any sane person should draw liquid from a cask and drink it without knowing anything whatever of its character; yet it is frequently done, and, in some instances, with fatal results. A sad fatality occurred at Aberlour, Strathspey, the other day from this unwise practice. It appears, from the particulars kindly supplied by a correspondent, that a labourer, while engaged in a garden in the village of Aberlour, finding a cask containing a liquid, drew a small quantity and drank it, under the impression that it was sour beer. Instead of the cask containing that harmless, if decidedly objectionable liquid, it contained a highly-poisonous weed killer, with the result that the poor fellow died within three hours of his having taken the fatal draught. It is very unwise for anyone to drink a liquid from a cask standing in a corner of the garden, for beverages are not usually kept in that way, but, knowing that it is done, all vessels containing weed killers should be kept under lock and key, and bear the inscription "Poison" in bold letters. Not only is it advisable that such sad accidents as this should be prevented, but is desirable that, as weed killers are great aids to the gardener in keeping the walks and drives free from weeds, they should not be brought into disrepute.

A Horticultural Students' Society has been formed in connection with the Essex County School of Horticulture. Towards the completion of the advanced course of instruction at the school last year, the students held a meeting and established a society with the above title. The object of the society is to promote home study and to encourage out-of-door observation of matters and things bearing upon horticulture. Each member undertakes to prepare once a year an original paper upon some gardening subject, such paper to be the result of actual study and experience on the part of the writer. These essays are circulated amongst the members, and notes and criticisms invited. The subjects discussed in the essays prepared in the course of the past winter are of an eminently practical character, and the one published in the quarterly journal of the Technical Education Committee evinces a sound knowledge of the subject dealt with.

An Experimental Station at Tunis has been instituted by the French authorities for the promotion of the sciences of agriculture, horticulture, and meteorology. It is hoped that this station, with its two years' course of instruction for students, its farm, trial garden, and oil refinery, will render valuable service and advice to resident and intending colonists. So far the Tunisian colonist has had no one to whom to go for information with respect to crops or climate, consequently everything is being pushed forward to enable the authorities to open the station in October next. It should be remembered that Tunis is mainly an agricultural colony, and even now cultivates annually a million acres each of wheat and barley, besides producing considerable quantities of wine and olive oil.

Our Imports of Potatos for the first four months of the present year reached the large total of 157,365 tons, or something like fifteen times as many as we did during the same period in 1897. The highest import for one week during the present year was 16,050 tons in the last week of April. Some folks are still urging that, in view of this huge import, British farmers should extend their cultivation of potatos largely; we think otherwise, for the need of such heavy importations was due to the poor crops of potatos produced last year in Ireland and the south-west of England—a failure that does not often occur, or, at least, is seldom so complete as in 1897.

The Great Temple Show.

(Concluded from page 350.)

Hardy Plants and Flowers.

Hardy plants and cut flowers of hardy perennials were, as usual, contributed in immense numbers, and although not in many instances staged so tastefully as could have been wished, they were highly attractive, and of much interest to visitors. Messrs. Barr and Son, 12, King Street, Covent Garden, and Long Ditton, staged a large and attractive collection, in which were admirably represented Genista hispanica pumila, one of the most useful of the dwarf shrubby plants for sunny banks; Aubrietia Leichtlini, a distinct form of these attractive spring flowering plants, and valuable for beds and the rockery; Achillea tomentosa, a handsome, free-blooming, yellow-flowered species; Spiræa palmata, charming as a pot plant; Gentiana verna, Arenaria montana, a beautiful white-flowered rock plant, not sufficiently grown; Saxifraga Camposi, a handsome mossy species, with large white flowers; Phlox divaricata, an American species, with lavender-coloured flowers, and of much beauty; Orchis latifolia, O. maculata, and other of the British orchids; Sempervivum chrysanthum, a distinct species, forming dense masses of pale green; Eremurus himalaicus, the finest of the several eremuri, and represented by several splendidly-developed spikes; Centaurea cyanus Victoria, an elegant form, free in blooming, and of much value for small decorations in a cut state; Trollins europæus, T. aurantiacus; Pæonia tenuifolia, an elegant species with single crimson flowers, and useful for the early period at which it blooms; double and single pyrethrums in great variety, Oriental poppies, Geum coccineum, Aquilegia californica, Campanula glomerata dahurica, a handsome form, the flowers deep-purple and freely produced. Very fine were the spikes of Eremurus robustus, less elegant but bolder in growth than E. himalaica, German and Spanish iris, single pæonies, The Bride gladiolus, and late-flowered tulips in great variety. Messrs. Barr and Sons also had a tastefully arranged miniature rockery, which deservedly attracted much attention.

MESSRS. FISHER, SON AND SIBRAY'S GROUP OF HARDY ORNAMENTAL TREES, TEMPLE SHOW.

Fancy pansies were shown in large numbers and fine condition by Messrs. Isaac House and Son, Coombe Nurseries, Westbury-on-Tyne. The flowers were shown on boards in the orthodox fashion, and in bold sprays, and produced an exceedingly pleasing effect. The firm also contributed several baskets of violas, the varieties of these including White Empress, a pure white bedding variety; W. Haig, rich blue; and A. F. Rowberry, one of the best of the yellow selfs. An attractive collection of hardy flowers was shown by Messrs. J. Cheal and Sons, Crawley, who had in the centre of the collection an artistically-arranged rockery clothed with alpines. Violas were well represented in the collection, as were hardy rhododendrons, Oriental and Iceland poppies, single pæonies, and German, or flag iris.

M. Koster and Sons, Boskoop, Holland, exhibited a large collection of cut flowers of varieties of Azalea sinensis, but in consequence of being staged in boxes in much the same manner as roses and the majority of florists flowers, they were less effective than they otherwise would have been. Anthony Koster, rich yellow golden; De Reichenbach, soft salmon-red; and Alma Tadema, soft cream yellow-tinted rose, may be mentioned as especially desirable for their distinctness and beauty. Mr. F. G. Foster, Havant, had a collection of sweet peas, including the leading varieties in the several shades of colour, which, arranged in neat bouquets with ferns, had a pleasing appearance. Mr. George Edom, Walton-on-the-Hill, sent a small but interesting collection of show tulips.

Messrs. George Jackman and Son, Woking Nursery, contributed a highly attractive collection of hardy plants in pots in which single and double pyrethrums were conspicuous by reason of their splendid development. From the Langport nurseries Messrs. Kelway and Son sent a magnificent collection of hardy flowers, in which the single and double pæonies were prominent. A semi-double white tree pæony, shown under the name of Jean de Reszke, is of surpassing beauty and well deserved the award of merit conferred upon it. Single and double pyrethrums, with a host of other good things for which the firm have long been distinguished were admirably represented, and contributed liberally to the attractiveness of the display. This firm also sent a collection of pæonies in pots, but these appeared to have suffered somewhat from the long railway journey, and did not represent the specimens at their best.

From Messrs. R. Wallace and Co. came an interesting and attractive group of bulbous and hardy plants in which lilies were largely shown. The lilies included Lilium longiflorum, L. Thunbergianum in variety, and the elegant L. tenuifolium. Flag iris were well shown, and especially interesting were the species of hardy lady's slippers, which one seldom sees at public exhibitions in such large numbers as in this instance. The cypripediums represented included C. occidentale, C. acaule, C. candidum, C. parviflorum, C. pubescens, and C. spectabilis. In the collection also were Watsonia Ardernei, Incarvillea Delavayi, ixias in variety, and Iris Korolkowi, of which the finest form is that known as Atrofusca.

Mr. Prichard, Christchuch, Hants, had a comparatively small but very interesting collection of cut flowers, in which Eremurus robustus Elwesianus was conspicuous. This form is an immense improvement upon the type, the flowers being much larger and more closely arranged on the spike. The inflorescence of the specimen exhibited was about two feet in length and six or seven inches in diameter.

Mr. T. S. Ware, Hall Farm Nurseries, exhibited a large collection of hardy flowers and alpine plants, which, arranged at the end of one of the long tents, produced a very pleasing effect. German iris, in great variety, were admirably represented, as were Cypripedium calceolus and other of the hardy orchids. The alpines included many beautiful plants, the saxifragas being especially noteworthy. The most conspicuous object in this fine collection was the magnificent spike of Eremurus robustus Elwesianus, on which an award of merit was conferred.

Mr. W. Sydenham, Tamworth, presented a lot of pansies and violas, the former being very well represented by large sprays of fresh flowers fragrant and handsome—Stephan, yellow; Lucy Franklin, white and yellow; Mrs. H. Bellamy, William Tell, Devonshire Cream, Charm, Mary Stewart, Acme, and Pembroke were notable sorts of excellence. Mr. Sydenham also had numerous designs in pansies and violas.

Messrs. T. Cripps and Sons put up a beautiful lot of well-grown Japanese maples in No. 4 tent, staging these on either side of the entrance. These were most effective, as the various colours which this section provides were associated in a most charming manner. All the best varieties were staged, and represented both by large specimens and elegant tiny plants.

Some beautiful rhododendrons from Mr. E. G. Reid, Beckenham Hill, Kent, made a pretty bank near the exit end of No. 2 tent; scarlet forms predominated, and in combination with massive heads of rosy-coloured varieties produced a fine effect. The plants were all dwarf, and well furnished with flowers and foliage. Messrs. Fisher, Son and Sibray's group of hardy ornamental trees, of which we give an illustration, was described in our issue of the 28th ult.

Fruit Trees in Pots.

Fruit trees in pots were presented in considerable numbers, and as they were mostly bearing good crops, they were by no means the least interesting of the several features. Messrs. T. Rivers and Son, Sawbridgeworth, contributed a collection of well-grown and heavily cropped trees of peaches and nectarines, and chief among the varieties represented were Early Rivers and Cardinal nectarines and Hale's Early and Alexander peaches, Monaco Bianco fig, and May Duke cherry. A large box of exceptionally fine fruit of Early Rivers nectarine was also shown by the firm. Mr. J. Hudson, gardener to the Messrs. Rothschild, exhibited a large collection of orchard house trees in pots. The trees were mostly of medium size and carrying excellent crops of fruit. Among the varieties represented in the collection were Belle d'Orleans, Governor Wood, Frogmore Early Bigarreau, Empress Eugenie, Bigarreau de Schreken, Elton, and Early Rivers cherries, Cardinal, and Lord Napier nectarines; Hales' Early, Early Grosse, Mignonne and Amsden June peaches; Early Transparent Gage, Jefferson, and Reine Claude Comte Althames plums. Grape vines were used with excellent effect for forming a canopy over the trees, the most noteworthy of these being Foster's Seedling and Black Hamburgh. Excellent strawberries were also shown, the fruit of Auguste Nicaise and Royal Sovereign being particularly attractive.

Greenhouse Plants.

An extensive and first-rate exhibit of hard-wooded plants from Messrs. Balchin and Sons, Hassocks, was a revelation to many of exceptionally high culture in these plants; there were big banks of Erica Cavendishi, a blaze of yellow; Erica Spenceri, deep rose; Erica perspicua nana, E. ventricosa rosea, deep pink; and the lovely rich blue Leschenaultia biloba major backed by the white Erica candidissima. The Messrs. Balchin had a lovely lot of well-grown plants that commanded admiration. Mr. Forbes, Hawick, put up a pretty display of his brilliant and free-flowering crimson-scarlet carnation named Yuletide; this is a fine form with broad segments and sturdy, erect habit. In front of these was a collection of pansies and violas in great variety and good quality.

A small group of cannas, remarkably dwarf and with compact spikes of brilliant flowers, came from Messrs. Paul and Son, Cheshunt, and served to illustrate the great value of these plants for conservatory decoration; Daniel Gerard, Mrs. F. Drees, gold and orange, Iona, crimson, and Miss Elsie Perkins, yellow, were notable and distinct forms of great merit. A bold and brilliant display of cannas came from Messrs. H. Cannell and Sons, Swanley. The plants were all robust and carried large spikes of magnificent flowers, notwithstanding that the plants were grown in small pots. For effective and gorgeous colouring the cannas quite equal the orchids. Half a dozen select varieties from Messrs. Cannell's collection are Madame La Barrone P. Thenard, orange; Alex Belliard, deep blood red; Madame Pichon, golden; Konigen Charlotte, scarlet and gold; Duchess of York, yellow, with scarlet spots; and Aurea, clear golden yellow.

Floral Designs.

Miss Edith Langton, Hextable, Swanley, had a pretty table decoration in blue-shaded Spanish irises, white saxifraga, and varigated phalarium; a simple but effective exhibit. The same lady also had a bouquet of pink roses. Miss Dalton, Ludgate Hill, set up some excellent bouquets of roses, associating crimson and yellow varieties; she also had a charming bouquet of cattleyas and odontoglossums, and a handsome wreath composed of liliums, lily of the valley, gardenias, and white gladioli. Miss Bradley, Gipsy Hill, showed epergnes of spiræa, white lilac, pancratiums, stephanotis, and other choice white flowers. Mr. W. Parkin, Sheffield, sent vases and epergnes of various flowers arranged by means of a pliable wire support that admirably answers the purpose of enabling one to arrange flowers to advantage with ease; it is a modification and great improvement over the wire racks already in use. Mr. Moyses Stevens, Victoria Street, Belgravia, had three grand floral arrangements. a basket of white liliums and pink pæonies; a wreath of liliums, stephanotis, and Caladium argyrites, and a harp of double white daffodils, Cattleya Mossiæ, and liliums.

Mr. L. H. Calcutt, Fairholt Road, Stoke Newington, had a tasteful display of arches, epergnes, and tall stands of flowers. In the centre was a tall stand of white liliums, yellow oncidiums, and long drooping racemes of Cymbidium Lowianum; this was a bold and handsome effort, especially as the base was finely finished with Lælia purpurata, Caladium argyrites, and anthurium spathes. Blue and yellow Spanish irises, yellow marguerites, and odontoglossums were the flowers most used in the other designs.

Messrs. Jones and Sons, Shrewsbury, showed some lovely bouquets and baskets of flowers; some of their most effective and artistic combinations were pink and crimson carnations; Lælia purpurata, and leaves of Cissus discolor; blue and yellow violas; bronze, yellow, and blue Spanish iris, pink roses and sweet peas.

Mr. F. V. Seale, Sevenoaks, staged an effective collection of floral arrangements, mostly wreaths and bouquets, in which bright colours and green foliage were extensively used. The use of evergreens seemed rather too free for light effect, but the asparagus and golden irises, and the white lilac and bronze pansies, were novel, as also was the chaplet of coloured pelargonium leaves.

Messrs. Perkins and Sons, Coventry, had, as usual, a beautiful set of bouquets and baskets chiefly composed of orchids and asparagus. The basket of yellow Oncidium sprays, Cattleya citrina, and Odontoglossum Halli, was a superb design. A bride's bouquet of white odontoglossums, stephanotis, and lily of the valley, was a beautiful effort; while the bridesmaid's bouquet of cattleyas and rosy odontoglossums, was at least as effective. The Messrs. Perkins thoroughly sustained their great reputation. Mr. J. Prewett, Lancaster Gate, Bayswater, showed a large number of his light and elegant silvered flower-stands in various designs, filling these charmingly with pink pelargoniums, white lily of the valley, roses, and rhodanthes.

Messrs. B. S. Williams and Son sent from their Piccadilly branch a first-rate lot of floral designs, and these were not too crowded. At the back was a telling bouquet of scarlet carnations and anthurium spathes, and a large mirror framed in double white narcissi, with sprays of odontoglossums and a basal bunch of fine cattleya blooms. In front was a sumptuous basket of orchids, with long elegant sprays of choice odontoglossums springing from a groundwork of Cattleya Mossiæ; asparagus frondage gave the necessary tone of greenery. A big basket of Malmaison carnations was also very effective and beautiful.

Ferns.

An occasional bank or group of ferns forms a relief to one's eyes in such a collection of gorgeous colours as the Temple Show provides; consequently, after leaving the bulk of the orchids, it was pleasant to view Messrs. J. Hill and Son's extensive exhibit of ferns in all shades of green. Arranged on tall stands were specimens of Asplenium caudatum, Davallia Mariesi, D. Fijiensis, Nephrolepis davallioides furcans, Lygodium scandens, and numerous other graceful and depending ferns. Below these were groups of Blechnum braziliense, Cheilanthes elegans, Adiantum cardiochlæna, Gymnogramma pulchella, G. Alstoni, Adiantum farleyense, A. rhodophyllum, A. macrophyllum, and Pteris ludens, with a margin of the most popular market ferns. Several Elk's Horn ferns gave character to the exhibit, which in every way was good, and included the new proliferous Asplenium Hilli.

Ferns in great variety were nicely arranged by Mr. H. B. May, Edmonton, who had a few large aspleniums and platyceriums, staged high above the general exhibit, and thus any idea of flatness was prevented. One fine plant of Platycerium grande was a great attraction, as it is without doubt the finest of the Elk's Horn ferns. Not only were popular ferns shown, but a great number of comparatively rare species and new varieties. Conspicuous and elegant ferns were Pteris longifolia Mariesi, P. Reginæ cristata, P. Polypodium Schneideri, very handsome; P. ludens, a bold species; Phlebodium Mayi, a new and especially elegant and graceful seedling from P. glaucum, dwarf in habit, and with waved pinnæ to the drooping and much-divided fronds. Other notable forms were Gymnogramma grandiceps superba, a fine golden fern; Lomaria ciliata major, the beautiful Pteris gracilis multiceps, Gymnogramma flavescens, and the bold and strong-growing Asplenium marginatum. Adiantums in variety, aspleniums, blechnums, davallias, and many other ferns also came from Edmonton.

A large and varied collection of ferns came from Messrs. W. and J. Birkenhead, Sale, Manchester, and if not quite so extensive as this firm usually puts up, it contained a good selection of kinds. The case of filmy ferns was a great attraction, as it always is. Trichomanes maximum and Todea superba were especially good; Polystichum angulare divisilobum densum is a beautiful hardy fern that was well represented; Athyrium filix fæmina Victoriæ regale is a fine form of a fairly well-known and elegant fern; the violet scented Lastrea fragrans was represented by a basket of neat little plants that, needless to say, were a source of great interest to the lady vistors. The plumose form of Polystichum divisilobum, with Asplenium trichomanes incisum, Scolopendrium vulgare crispum robustum, Athyrium f.-f. grandiceps, and A. f.-f. cruciata grandiceps, were other notable and graceful hardy British ferns. In addition to these, there was a collection of elegant adiantums, selaginellas, gymnogrammas, and other stove and greenhouse ferns.

Fruit and Vegetables.

A tasteful as well as excellent display of vegetables was staged by Messrs. Sutton and Sons, Reading, and palms, ferns, and selaginella were freely used, and amid these were set up baskets of the firm's newer peas, all represented by full pods even at this early date; the variety mostly on view was Early Giant, and one basket of fine pods was forwarded to Marlborough House for the Derby dinner of H.R.H. the Prince of Wales. The cucumbers were splendid developments of such useful sorts as Pride of the Market, Sutton's Peerless, Sutton's A1, a grand and handsome variety, and Matchless.

Messrs. G. Bunyard and Co., Maidstone, put up a splendid lot of apples, arranged to demonstrate how long fruit may be kept in a properly constructed fruit-room. It is scarcely necessary to enumerate the varieties, but there were excellent dishes of Farmer's Seedling, Wagener, Winter Peach, Annie Elizabeth, Calville Rouge Precoce, Cox's Orange Pippin, Winter Queening, Newton Wonder, King of Tompkins County, Flanders Pippin, Reinette du Canada, Murfitt's Seedling, Wadhurst Pippin, Hoary Morning, and Alfriston. Some eighty dishes of fruit were staged, and Mr. Bunyard ably demonstrated their keeping qualities under suitable conditions. Figs in pots formed a backing to the apples.

Mr. J. McIndoe, gardener to Sir J. Pease, Bart., Hutton Hall, Guisborough, contributed a collection of fruit consisting of some twenty-five dishes, all of which were more or less good. Of special merit were the Black Hamburgh and Early Summer Frontignan grapes, Early Rivers and Dryden nectarines, Condor and Grosse Mignonne peaches, Black Tartarian cherries, Yorkshire Beauty and Scarlet Premier melons, Brown Turkey figs, Royal Sovereign strawberries, Scarlet Nonpareil and McIndoe's russet apples, the latter a large and handsome variety.

Mr. E. Beckett, gardener to Lord Aldenham, Aldenham House, Elstree, exhibited a comprehensive collection of vegetables, each dish so good as to render it difficult to make a selection. The broccoli and cabbages were arranged in neat mounds, consisting of about ten superb heads each, and relieved the flatness usually associated with large displays of vegetables produced by private cultivators. The broccoli included Late Queen, Model, Perfection; the cauliflowers, Extra Early Forcing, a valuable variety for use thus early in the season; the tomatos, Dwarf Champion, Duke of York, and Perfection; the cabbages, Ellam's Early and Flower of Spring; the peas, Early Morn; the potatos, Sharpe's Victor, Snowdrop, and Harbinger. Very fine also were the Lyon leeks, Moore's Cream vegetable marrows, Beckett's Victory cucumbers, mushrooms, Green Globe artichokes, and large Paris cabbage and Bath cos lettuces.

Mr. W. J. Simpson, gardener to Miss Wingfield, Ampthill House, Ampthill, exhibited a very large collection, somewhat uneven, but on the whole highly creditable to the cultural skill of the exhibitor. The most noteworthy examples were those of Model leek, Eclipse, Late White, Summer, and Champion broccoli, Warden Park tomato, Model, Early Hartwell, and Jersey Wakefield cabbages, Model and Cardiff Castle cucumbers, and Victor potato. Mr. Simpson also exhibited peas, French beans, and tomatos in pots, which evinced high-class cultural skill, and, arranged along the back of the collection, added much to the general effect.

Mr. Hayes, gardener to the Marquis of Northampton, Castle Ashby, Northampton, staged a comparatively large collection of vegetables, which was of interest as demonstrating the success with which esculents are cultivated in these great gardens.

Rhubarb and asparagus were admirably shown by Mr. F. Chapman, Colchester, the latter being of special interest as indicating the success with which this toothsome vegetable is grown in the neighbourhood of Colchester. Mr. Chapman also exhibited a selection under the designation of New Pea Green, which differs from the ordinary type in the tips of the growths being a light green.

A large exhibit of produce came from the Horticultural College, Swanley, and consisted of a large lot of Sutton's Matchless cucumbers, both cut and growing on the plants; there were early peas in pots, mostly Early Marrowfat, American Wonder, May Queen, and Chelsea Gem; tomatos, Early Ruby and A 1 were good, so also were the early potatos, broccoli, and French beans; mushrooms, asparagus, spinach, radishes, leeks, lettuces, &c., were staged in abundance and fine quality. Mr. J. Nicholls, Lower Tooting, sent samples of a new and early celery named Forcing White; a very early variety; Gross Mignonne peaches of high quality were shown by Mr. Ryder, gardener to the Dowager Countess of Limerick, St. Albans. A grand lot of mushrooms were sent by Mr. George Mount, Canterbury. Mr. G. Featherby, Gillingham, Kent, staged some splendid Hale's Early peaches, Dryden nectarines, early Black Hamburg grapes finely coloured, and some good examples of Covent Garden Favourite cucumbers.

A splendid lot of mushrooms staged by Mr. R. E. Addey, Ealing Road, Brentford, were greatly admired, and around them was a continual circle of gardeners. Mr. Addey showed bricks of his spawn, clusters of mushrooms just appearing, small buttons, larger mushrooms, and full-sized, all of which were well arranged. Mr. L. Mortimer, Rowledge, Farnham, had a splendidly grown lot of tomatos and cucumbers: Eclipse, Sutton's Abundance, Perfection, Conqueror, and Sutton's A1, were fine tomatos staged in boxes; while Tender and True, Telegraph, Sutton's A1, Rochford's Market, and Lockie's Perfection were the varieties of tomatos. Some yellow seed-fruits of cucumbers attracted a great deal of attention. Mr. W. L. Bastien, gardener to A. Henderson, Esq., M.P., Faringdon, sent a splendid lot of Perfection and A1 tomatos; A1 and Telegraph cucumbers, a number of golden skinned seedling melons, and some good French beans, and Walcherene cauliflowers. Mr. Beckett, gardener to Lord Aldenhan, Elstree, sent fine specimens of Sutton's Masterpiece, Countess, A1, Blenheim Orange, and Aldenhan Perfection melons. Mr. T. Robinson, Hollingbourne, also sent a small set of well-grown melons; and Mr. Miller, gardener to Lord Foley, Esher, sent a box of Royal Sovereign strawberries. A bundle of wonderfully large Giant asparagus was sent by Mr. W. Godfrey, of Colchester; it was of immense size.

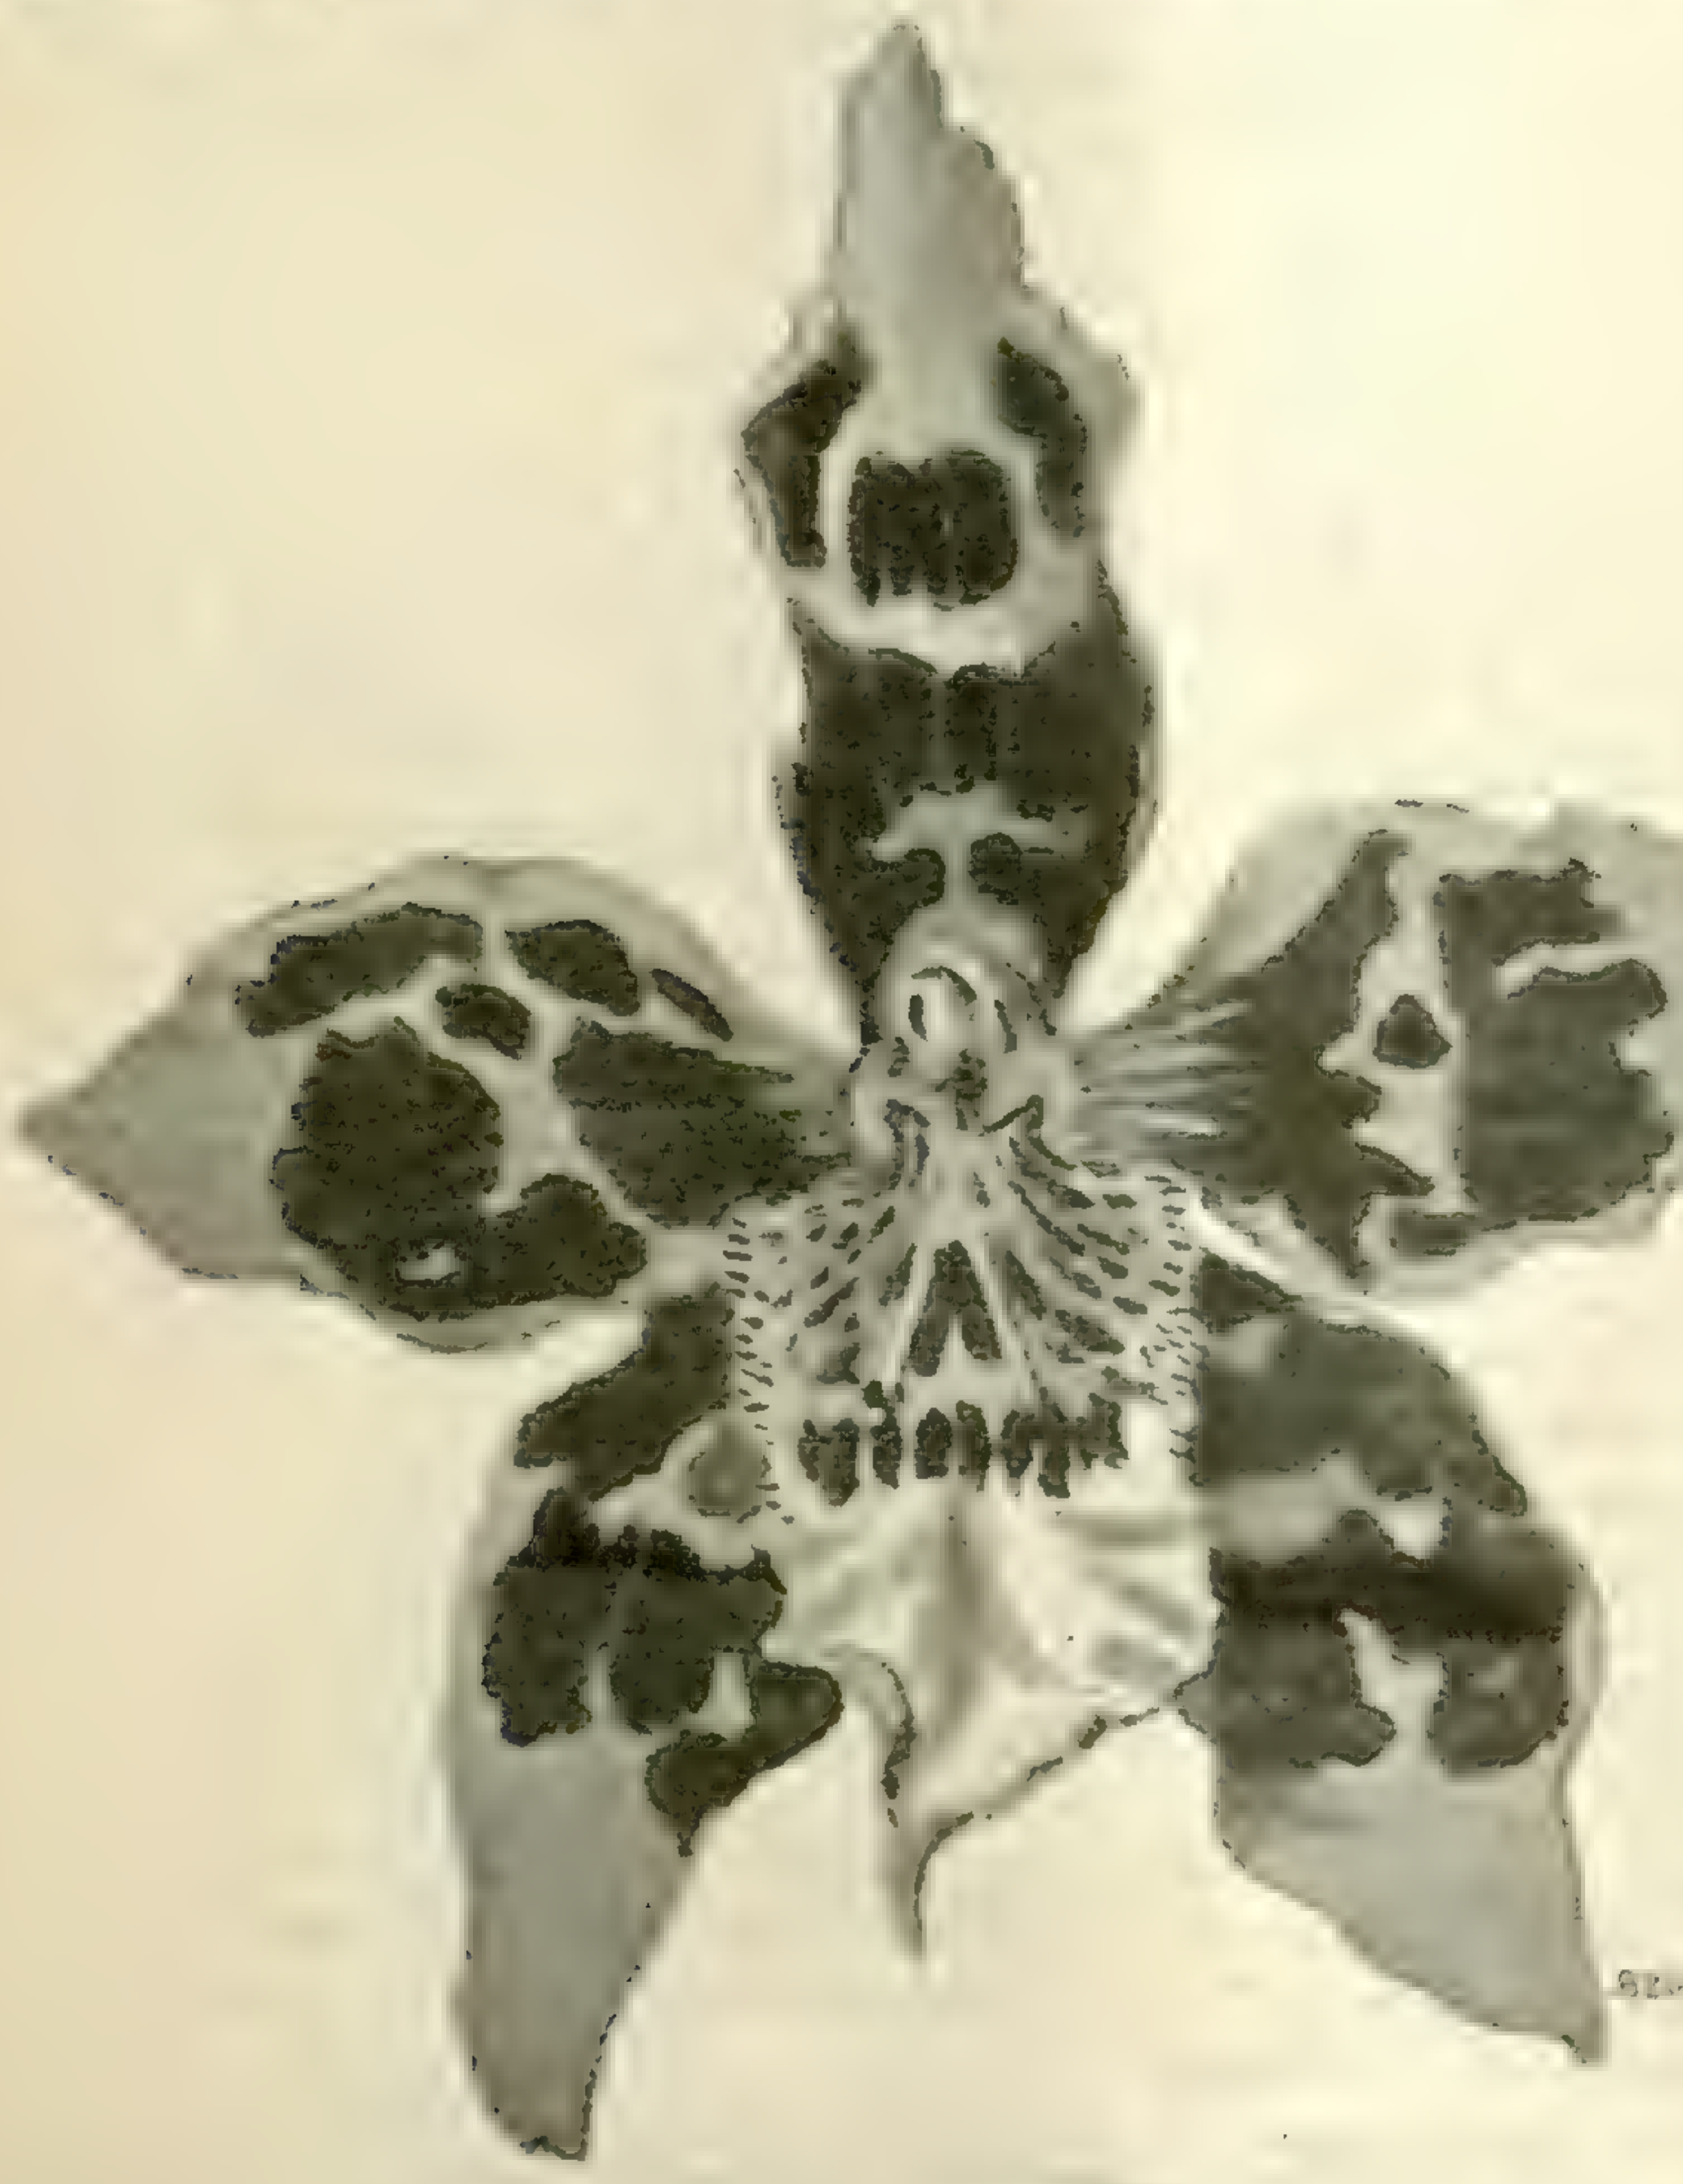
NEW PLANTS, FLOWERS, AND FRUIT.

CATTLEYA MENDELI MRS. E. V. LOW.

A BEAUTIFUL form of a beautiful orchid, having broad white sepals and petals, and a pretty purple tipped lip. The tube of the lip is white on the outside, but rich yellow within, this colour extending towards the broad apex. The purple is not very dark, and into it there run veins of white from the frilled white margin. The petals are of immense width and great substance, and altogether the form is first-rate. A.M., R.H.S., May 25. Messrs. H. Low and Co., Bush Hill Park, Enfield.

ODONTOGLOSSUM CRISPUM-HARRYANUM.

Among the distinct orchids at the Temple Show few attracted more attention than the odontoglossum that is presumably a natural hybrid between O. crispum and O. Harryanum, as its name implies. It is an open spreading flower of large size, and having the general characteristics of O. Harrayanum, but more expanded, and of a lighter colour. The ground work is pale nankin yellow, and, except at the tips of the sepals and petals, is heavily blotched with reddish brown, the markings sometimes extending right across the segments. The lip is pale yellow, and only spotted at the base with reddish crimson, having a fine golden crest; the lip is flat, broad, and with a sharp pointed apex. F.C.C., R.H.S., May 25. Mons. C. Vuylsteke, Loochristi, Belgium.



ODONTOGLOSSUM CRISPUM-HARRYANUM.

CATTLEYA MENDELI OAKES AMES.

A particularly handsome form, with rosy lilac sepals and petals and a brilliant purple apex to the finely formed lip. The broad petals had at their apices an irregular blotch of rich purple that is most attractive and distinct. The lip is very compact, and has a bright yellow throat; the apex is rounded, exquisitely fringed, and frilled, this colour extending well into the centre of the throat. The sepals are of a lighter lilac shade than the petals. F.C.C., R.H.S., May 25. Messrs. H. Low and Co., Bush Hill Park, Clapton.

DENDROBIUM DALHOUSIANUM SALMONEUM.

A wonderfully distinct variety of a well-known and bold-flowered species, differing principally from the type in the softening of the colour and, to a large extent, in the elimination of the side blotches in the lip. The flowers are large, borne as freely as in the species, and of a soft salmon-buff shade. The two blotches in the lip are of a peculiar red hue, brighter than a deep rose. F.C.C., R.H.S., May 25. Messrs. Hugh Low and Co., Bush Hill Park, Clapton.

LÆLIO-CATTLEYA ADMIRAL DEWEY.

A bold hybrid of great beauty, robustness and freedom of flowering. This orchid derives its origin from Cattleya Warneri formosa and Lælia elegans Mastersi; it partakes largely of the L. purpurata character, but has a glorified lip. The sepals and petals are of a beautiful shade of light purplish rose, the sepals being narrower and lighter in colour than the wavy petals. The tube of the lip is very broad, bright rose-purple, with darker veins; inside there are two light creamy patches on either side of a central band of royal purple. The mouth of the lip is fully two and a-quarter inches across rounded, with waved and crisped margin, and of a grand rich red-purple colour, though with a lighter wire edge. Four flowers were borne upon the spike shown, and each bloom was over six inches across without stretching out the segments. F.C.C., R.H.S., May 25. Messrs. Charlesworth and Co., Heaton, Bradford.

CATTLEYA FERNAND DENIS.

A remarkably distinct hybrid between Cattleya Acklandise and C. gigas; the former parent has dwarfed the habit and altered the shape of the latter, but has not affected the colouring so much as might have been imagined. The flowers have a spread of over five inches, and stand up boldly at the apex of the diphyllous slender pseudo bulbs. The sepals are from half to three-quarters of an inch across and nearly three inches long, blush, with pink veins, and having a few irregular spottings of purple at the apices. The broad petals are waved, and have their lateral margins reflexed a good deal, blush tinted, with a hint of lilac colouring. Lip large and open, the side lobes standing erect and wide apart. The central lobe is very broad and rounded, waved, and slightly fringed, deep purplish-carmine, with a band of palest yellow across the base, when the side lobes commence. Throat and column pale purple. This beautiful cattleya was figured in our issue of the 28th ult , under the name of C. Fernand Devis as inscribed on the accompanying card; but the name now given is correct. F.C.C., R.H.S., May 25. Messrs. Charlesworth and Co., Heaton, Bradford.

ACALYPHA SANDERI.

This is a bold, novel, and distinct species, with large ovate deep green leaves set on long light green petioles. From the axil of each leaf a long inflorescence springs, and this is the most attractive feature of the plant, for these are like long crimson tassels, measuring from a foot to twenty inches in length and sometimes an inch in diameter, and like nothing so much as crimson plush, so closely are the flowers placed together. It is a striking plant, and one that will be used largely for decorative effects, grouping, &c. It is a stove plant that when grown to the side needed can be kept in condition in an intermediate house or warm greenhouse for some time. In the case of especially strong plants there are sometimes two to five long long tassels of flowers from the axil of certain leaves. This plant was described in our report of the Ghent show a few weeks back, and figured in our last issue. F.C.C., R.H.S., May 25. Messrs. F. Sander and Co., St. Albans.

LICUALA JEANENCEYI.

This is a handsome palm that can scarcely fail to become popular, for it is elegant, and clothes itself to the base with frondage. The fronds are fan-shaped, but instead of being entire, as in a latania, they are divided to the base into seven or eight divisions; these are squared at the apex, but notched with bifid divisions to the depth of half an inch. The frondage is of a clear, deep green colour that recommends itself. F.C.C., R.H.S., May 25. Messrs. F. Sander and Co.

CALADIUM AMI SCHWARTZ.

A curious caladium, with leaves that endeavour to be cordate but have not their basal lobes much developed; the colour is deep bronzy-crimson, with veins of bright scarlet, and over the whole a sheen-like varnish. This is the result of crossing C. albanense with Madame J. Box. A.M., R.H.S., May 25. Messrs. F. Sander and Co., St. Albans.

CALADIUM GUARATINGUATOR.

Previously described in our columns; a bold caladium of a brilliant scarlet shade, with bronze-crimson mottlings making a broad marginal band. Very handsome. A.M., R.H.S., May 25. Messrs. J. Laing and Sons, Forest Hill.

ROSE AURORA.

A bold and large-flowered hybrid tea rose, having handsome sweetly-scented flowers of a delicate and charming shade of soft pink. The rounded petals are of great size, breadth, and substance, and with a pretty curl along the rounded upper margin. In habit the plant is all that could be desired, judging from the specimens staged; it will be a grand acquisition to its class. A.M., R.H.S., May 25. Messrs. William Paull and Son, Waltham Cross.

LÆLIO-CATTLEYA GOLDEN GEM.

A pretty and distinct hybrid obtained by crossing Cattleya intermedia with Lælia flava var. splendens. The growth is that of L. flava, and the flowers show great evidence both in shape and colour of its influence as a parent. The sepals and petals are half an inch across, nearly two inches long, and of a pretty golden shade of great depth; the petals point forward, and the sepals spread out. The lip is narrow, and has a long lemon-yellow tube formed of the clasping side-lobes; the tips are bright yellow; the apical lobe is of a rich deep crimson colour with purplish-crimson veins, and a tint of brown showing through the crimson. A.M., R.H.S., May 25. Messrs. Charlesworth and Co., Heaton, Bradford.

CATTLEYA MENDELI AMELIA.

A handsome and large-flowered variety with pure white sepals and petals, and a lip that is white save for a faint purplish blotch near the apex and a buff shade in the throat. The petals measure two and a half inches across, and are proportionately long; the sepals are an inch wide. A.M., R.H.S., May 25. Mr. J. Barker, gardener to W. P. Burkinshaw, Esq., West Hill, Hessle, Hull.

ODONTOGLOSSUM PESCATOREI BELLATULUM.

A very distinct form of a pretty orchid, and one that has branching spikes of elegant flowers. On the white ground there is one round rich purple spot at the centre of each petal, while at the apex of each sepal is an irregularly triangular blotch of the same rich rose-purple colour. The small lip has the usual crest and a few spots of purple. A handsome orchid. A.M., R.H.S., May 25. Messrs. Linden and Co., Brussels.

ODONTOGLOSSUM CRISPUM DECORUM.

A charming odontoglot of large size, and with wonderfully substantial segments. The sepals and petals are white, with a creamy tinge at their apices. One irregular and rather large intense crimson-brown blotch appears in the centre of each petal, while one big blotch or cluster of spots of the same deep, rich colour is placed about the centre of each petal. The shapely lip has rich, but small, spots strewed over the white ground, as well as on the golden disc. A.M., R.H.S., May 25. Messrs. Linden and Co., Brussels.

ODONTOGLOSSUM CRISPUM ZEBRINUM.

A pretty and attractive form, with finely-shaped flowers about two and a-half inches across. The ground colour is whitish, with a creamy suffusion. All the segments are spotted and barred with deep reddish-brown, the colour showing right through the flowers. The spike staged carried a dozen exquisite flowers. A.M., R.H.S., May 25. Messrs. Linden and Co., Brussels.

MILTONIA BLEUEANA ROSEA GIGANTEA.

A marvellously fine orchid, carrying eight huge blooms that are too flat to be graceful, but are most effective. The sepals and the spreading lip are palest blush, while the petals are shaded with rose, the colour being most intense at the base. At the base of the lip is a salmon-pink spreading disc. The lip is three and a-half inches broad, and the flower is four and a-half inches across at its widest. A.M., R.H.S., May 25. Mons. Jules Hye Leysen, Ghent.

ODONTOGLOSSUM CHARLSEANUM.

A curious and also pretty odontoglot, having creamy flowers on which the red-brown spots and blotches are so thickly disposed as to almost blot out the ground colour. The spotting is prettiest on the petals, for the sepals are rather blushed than spotted. The backs of the sepals are shaded deep rose, and this tint comes through to the front slightly, giving a curious effect. A.M., R.H.S., May 25, Mons. A. Madoux, Anderghem.

ANTHURIUM SCHERZERIANUM VAR. SENATEUR MONTEFIORE LEVI.

An attractive form with a long round spathe. French white, with an abundance of tiny dots of intense scarlet strewed over the surface. These dots congregate around the margin and down the centre into circular clusters that have a fine effect. A most distinct anthurium. A.M., R.H.S., May 25, Mr. L. de Smet Duvivier, Ghent, Belgium.

Phlebodium Mayi.

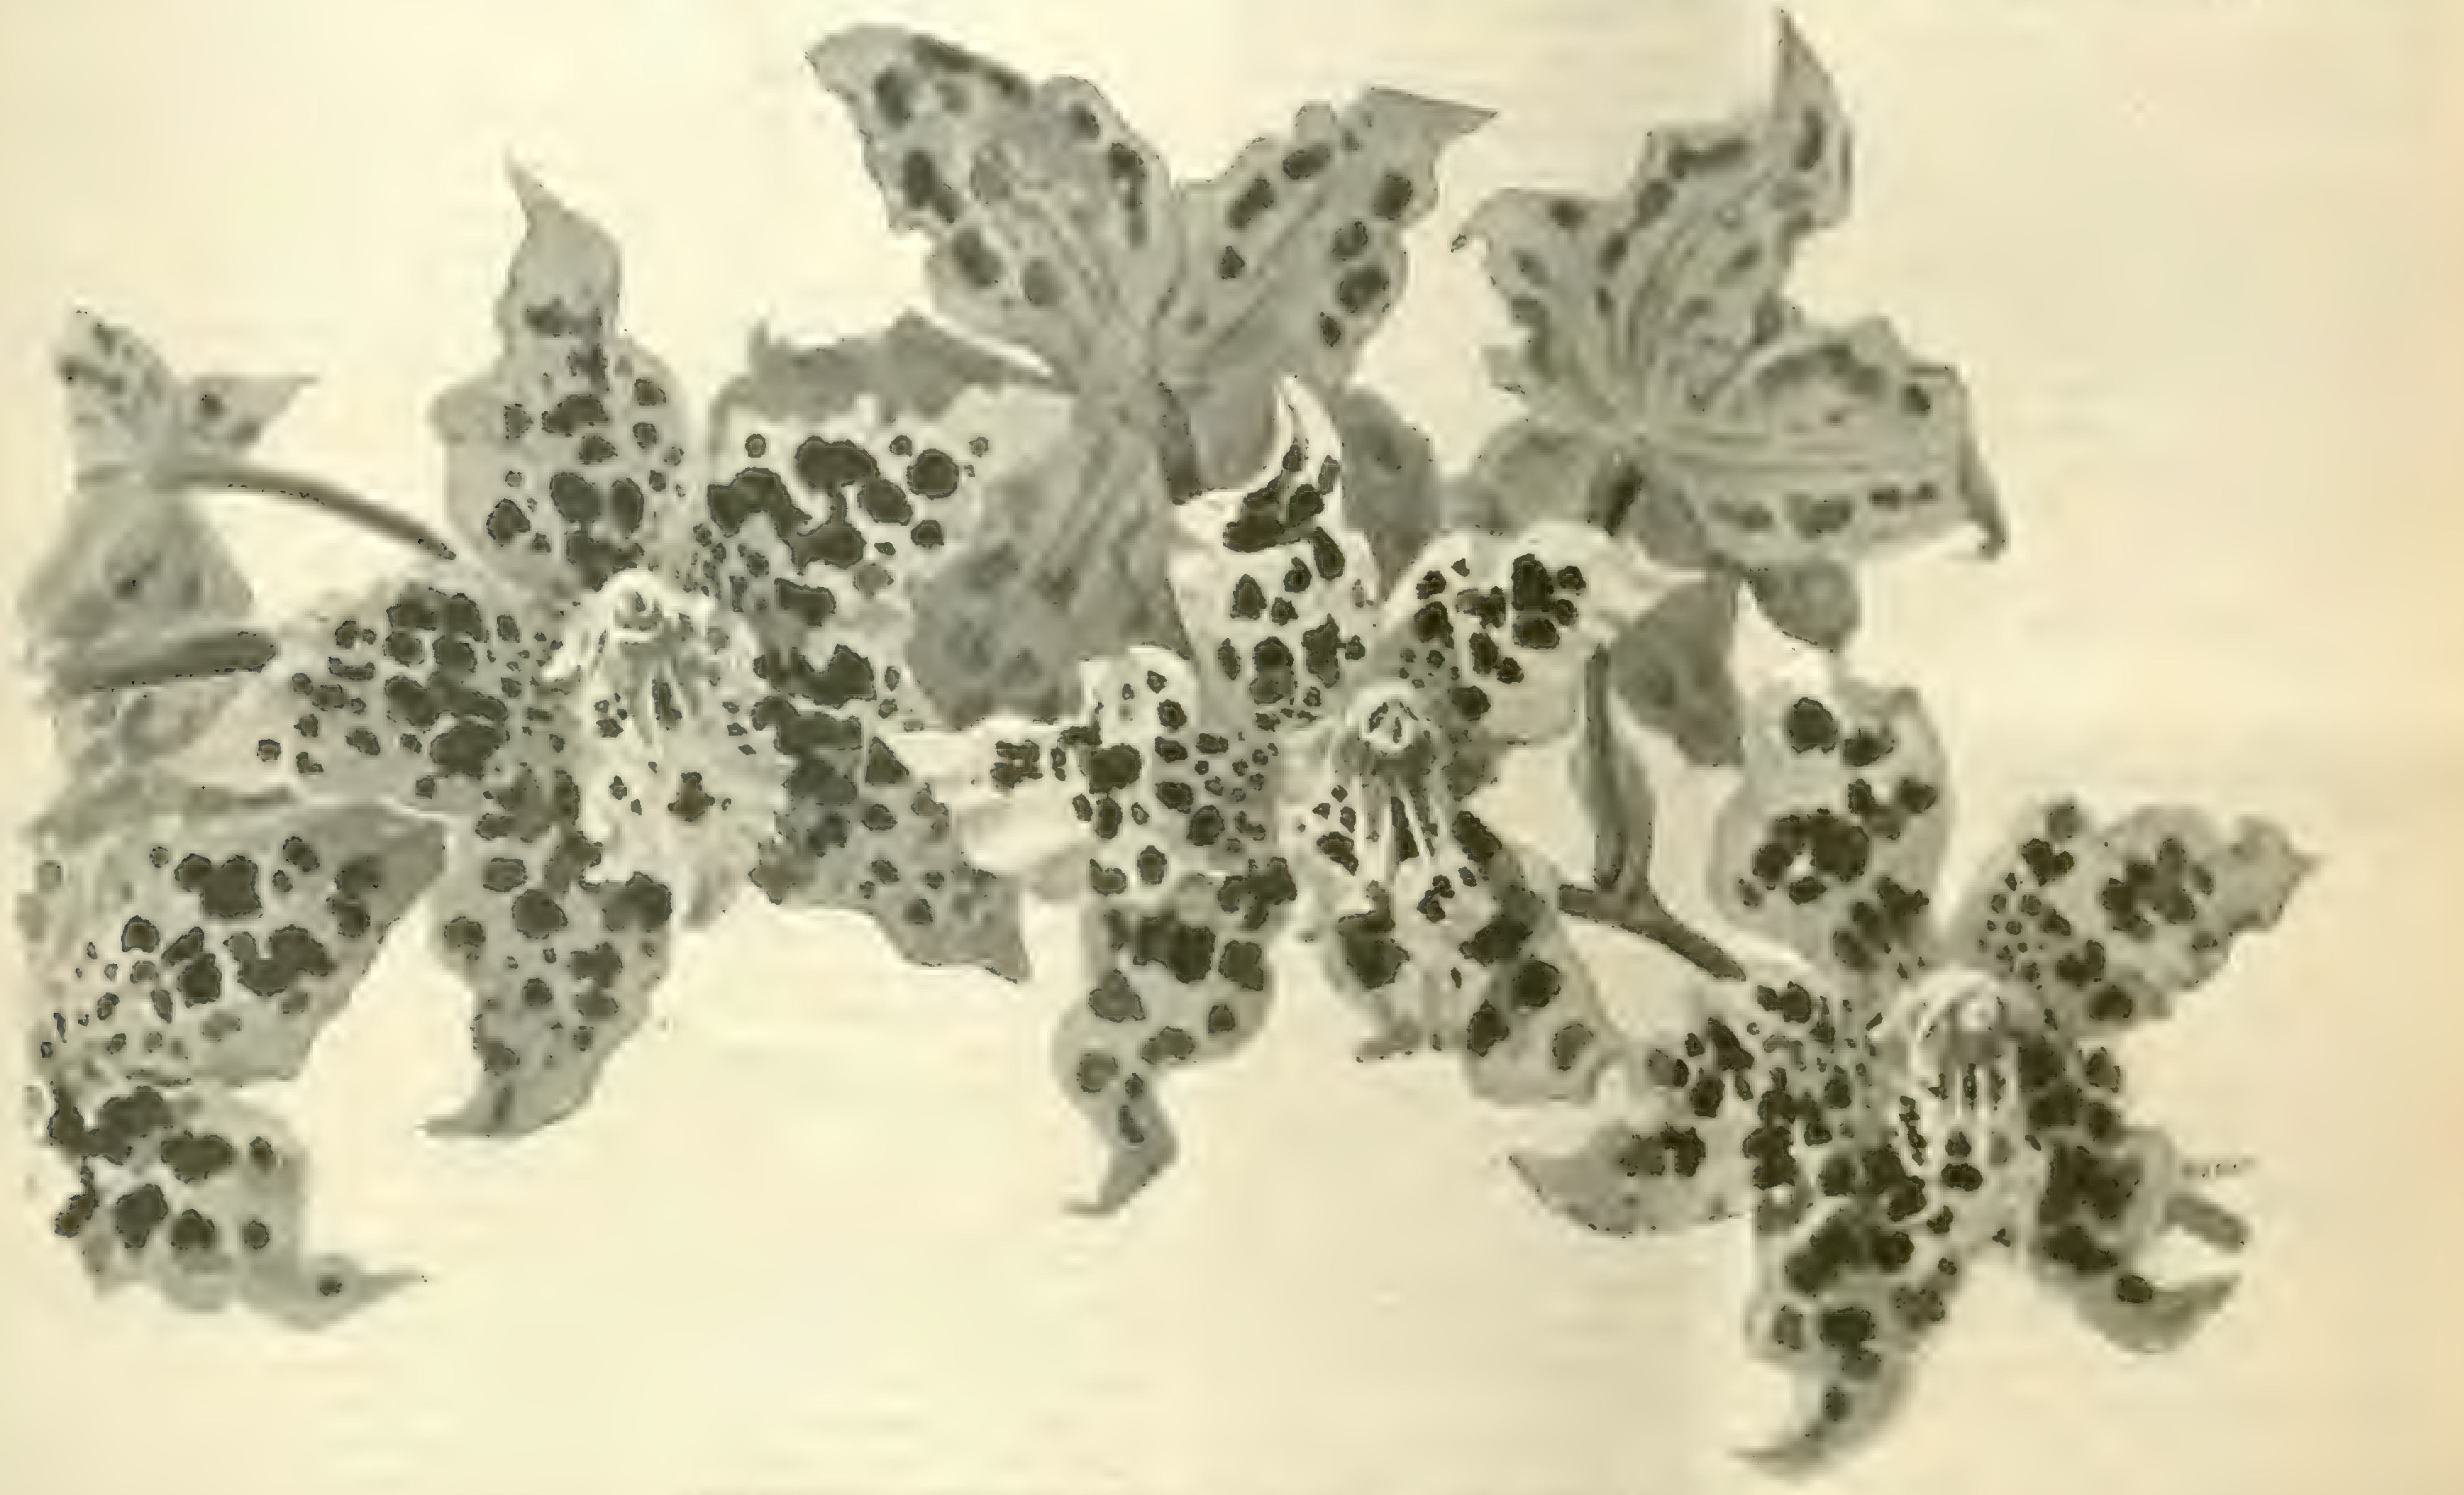
This is an elegant, distinct, and novel fern that will no doubt have to be classed as a variety of Phlebodium glaucum. It is probably not a true seedling from this species, but it is closely related to it. The fronds are a foot across, and divided almost to the rachis; there is a green tint associated with the general glaucous hue, and this, with the blue green tint seen in the veins of young fronds render the plant most attractive. In addition to the elegance of division and colour there is the beauty of undulation seen in all the pinnæ, and the secondary division also. There is a sort of regular irregularity in the whole contour of the plant that is extremely pleasing. If it proves amenable to general cultivation there is a great future before Phlebodium Mayi. F.C.C., R.H.S., May 25, Mr. H. B. May, Edmonton.

Eremurus robustus Elwesianus.

A gigantic eremurus, growing to a height of six feet, and carrying a spike that is at least forty inches long, though about eighteen inches of the lower part had been cleared of dead flowers. The individual flowers are of a pinky blush shade, with a deep pink vein down the centre of each segment; each bloom is about an inch and a half across. A. M., R.H.S., May 25. Mr. T. S. Ware, Hale Farm, Tottenham.

Odontoglossum Adrianæ var. venustum.

A beautiful and most distinct natural hybrid odontoglossum with charming flowers, having a creamy ground colour, over which are scattered in great profusion variously shaped bright red-brown spots. The flowers measure fully three inches across, and there were fifteen of them on a long graceful spike. When the plant is fully established this should make a grand orchid, for already it is a most beautiful one, and was the finest and most interesting odontoglossum in the show. All the segments are pointed, with waved margins, and with a slight fringing on the petals; the spotting almost become blotches on the lower sepals, but are smaller—mere dots at the base of the petals. The combination of colour is very good. O. Adrianæ var. venustum is undoubtedly a natural hybrid between O. crispum and O. Hunnewellianum. F.C.C., R.H.S., May 25. Messrs. Linden and Co., Brussels.



ODONTOGLOSSUM ADRIANÆ VAR. VENUSTUM.

Begonia Mrs. Dunbar Wood.

A handsome camellia-flowered begonia of large size, fine shape, and great substance. The outer segments are prettily fringed, and the whole flower is coloured with a novel shade that might be described as bright golden apricot. The segments are rounded, and some are speckled with creamy white. A. M., R.H.S., May 25. Mr. T. S. Ware, Tottenham.

Tree Pæonies.

Jean de Reszke: An extremely beautiful single-flowered form, with immense white petals, and a central cluster of golden anthers.

Sir Henry Irving: This is a wonderfully intense ruby-crimson form, single, with giant segments of great breadth; a very telling form.

Julius Cæsar: An extremely fine crimson-scarlet, semi-double form of exceptional brilliance and size; a grand colour A. M., R.H.S. to each, May 25. Messrs. Kelway and Son, Langport.

Auricula Snowdrop.

An interesting auricula but not one possessed of great beauty. It is certainly very distinct and novel, for it is perfectly double, and of a soft creamy white shade. It is the result of twenty years' careful seeding and selecting, and probably is the [illegible] plant of its kind in existence. Raised by the exhibitor. A.M., R.H.S., May 25, Mr. R. Dean, Ranelagh Road, Ealing.

Lilium rubellum.

A charming new species of lilium with shapely medium-sized blooms of a pretty rose shade, though the shade of colour varies from rosy blush to deep reddish rose. The growth is slender and the leafage small. Each flower is about three inches across at the mouth and three inches long in the tube. The average height of the plant is eighteen inches. The species has been named by Mr. J. G. Baker, of Kew, and has been found perfectly hardy during the past two winters; it will take its place among the very many beautiful Japanese plants we now have, and occupy a foremost position for bedding liliums. F.C.C., R.H.S., May 25, Messrs. R. Wallace and Co., Colchester.

Phyllocacti.

Agathea.—This is a very fine form, exceedingly free flowering, and producing big blooms of the brightest salmon-pink hue. A lovely variety.

Epirus.—A particularly large-flowered form with extra broad and fleshy segments of a lovely soft rose colour; this is a variety that attracted the ladies' attention as much or more than any other. A.M., R.H.S., to each, May 25. Messrs. J. Veitch and Sons, Chelsea.

Apple Ontario.

A handsome apple, rounded in outline, but with fine subdued ribs. The colour is yellow with a rich crimson scarlet cheek on the sunny side. The eye is large and half open, leafy, set in a deep and broad basin; stalk stout, set in a deep cavity. This is a famous long-keeping apple that should prove useful for late culinary purposes. A.M., R.H.S., May 25, Messrs. G. Bunyard and Co., Maidstone.

Holly Golden King.

A fine hardy holly, with showy broad foliage that in its younger state shows a pretty combination of gold and pale green. The older leafage is yellow with dark deep green centre, the markings being irregular. This variety has proved its hardihood at Carlisle, and grows very vigorously after the season has commenced. It is a sport from the Hodgson's holly, and this should recommend it. A.M., R.H.S., May 25, Messrs. Little and Ballantyne, Carlisle.

Whitewashing Peach Trees.—There is a great deal of truth expressed in the views of the grower to whom "D. T. F." (p. 283) alludes in his notes on the above. Protection, except when of the lightest description, often does more harm than good, as it renders trees and their fruits less hardy. As regards retarding by whitewashing, this might be a very good thing if we only knew the date or dates on which severe frost might be expected, and on the other hand it might be the worst possible thing to do. To illustrate what I wish to convey I may say that hundreds of apricots were killed here by the sharp frosts experienced on the nights of April 23 and 24, when we registered 12 and 10 degrees of frost respectively. The same thing happened in a lesser degree to peaches, but the fruits killed were those below a certain size, while the larger ones escaped either entirely, or with a slight bronzing. Had these fruits been retarded, so that the biggest were only as big as those killed, the whole crop would have been destroyed. Again we almost invariably have some sharp touches of frost in May, and I find that the bigger the fruits are when this happens, the more likely are they to escape injury. It may be said that by retarding we surely escape some frosts, but it is the severity of one frost which comes at an inopportune time, and not the number of frosts, which we have to fear; and my records here tell me that we are as liable to have 12 degrees of frost between the middle of April and the middle of May as we are earlier in the spring, and that no garden trees could be retarded sufficiently to make sure of escape. Whitewashing may and does retard the buds, but when once they burst it secures them no further immunity from injury. In America, where the springs come with a rush, and where there is rarely any further harkings back to winter, retarding must be of very great value, but we are placed differently, and hardly ever know when winter has quite departed.—J. C. Tallack.

TREE PYRUSES.

THE excellent illustration of the Sikkim apple (Pyrus sikkimensis) in your issue of May 14, portrays not only a beautiful, but an extremely interesting tree, being probably the most northern representative of the Malus section of pyruses. But the fact that there is probably not a nursery in this country from which it could be obtained, shows that either its value has been overlooked or ignored by nurserymen. To all intents it is an apple tree, and, beautiful though it undoubtedly is, an edible fruited apple gives much the same effect in flower, with the additional merit of autumn fruit—a second phase of beauty. The value of a tree to plant for ornament in private gardens from a nurseryman's point of view is generally the correct estimate of the merits of a hardy tree or shrub for general culture, and in these days of enterprise and rivalry, they do not knowingly allow a tree, shrub, or plant of commercial value (as they term it) to remain in the comparative obscurity of a botanical collection. It is, perhaps, well that such is the case, otherwise our great national collection of plant life at Kew would be robbed of much of its unique interest if the rarer species were to become distributed everywhere. One has often to deplore the fact that such an interesting plant cannot be obtained in nurseries as formerly. Nurserymen will tell you that "it does not pay" to grow them now as did it their fathers and grandfathers. We are so very commercial nowadays, that even plants are regarded from a strictly business point of view.

While dwelling upon this rare Sikkim tree one's thoughts naturally turn to others of its tribe which have best yielded their tribute of flower beauty for another season. Out of the dozen species of Malus enumerated in the Kew list half of this number are still rare beyond botanical collections; the rest are among the most popular of small flowering trees. One of the finest is the little Japanese tree crab P. floribunda, and this has become a quite common tree throughout English gardens, though its first introduction was comparatively recent. There is no need to describe such a familiar tree, and it cannot well be confused with any other, its slender growth of branches forming a spreading head rarely about ten feet high, at once distinguishes it when out of bloom, and at flowering time every branch is densely wreathed with the pale pink flowers, the opening buds being a rich crimson, a charming contrast to the pink open blossoms. The variety Atrosanguinea is regarded by many as a much finer form, the open flowers being of a much deeper pink than those of the type, but there is not such a marked contrast of tint between the buds as in the original form. Both are first-rate, and should be planted in a group together. The plants from a nursery reach mature growth in about the third or fourth year after planting, and these are especially fine if the soil is good or such as where apples grow well. The semi-double flowered variety Halleana or Parkimanni has the merit of retaining its flowers for a longer time than do the single forms, and for this reason is desirable. It is of the same colour as the type, and the three together make one of the choicest of groups for a lawn, standing out singly, not jostled with common shrubs or trees.

P. spectabilis is a much larger tree, and in my estimation the finest of all the maluses. Nothing surpasses this tree when first in full beauty of flower. It has all the profusion of bloom and richness of colour of P. floribunda, with a loftier and more imposing head. Its flowers are semi-double, and last a fortnight or three weeks in perfection. It is only as old specimens one sees the true beauty of this Chinese crab-tree, and, like the common apple, it takes a long time to mature. As its natural growth it is a stemmed tree. It is an ideal tree on a lawn, and the little floribunda may be grouped round it with fine effect. Though it has been in gardens for over a century it is not common, and nurserymen say they are seldom asked for it. Loudon, in 1838, said "No garden, large or small, should be without this tree." The same remark should be repeated to-day. There is a double variety, flore pleno, grown in nurseries, and a white or whitish variety (flore-albo).

P. coronaria, called the Garland Flowering Apple, is, like P. spectabilis, an old tree, brought first from America in 1724, and this also Loudon said should be in every garden. Beautiful though it is undoubtedly, I should not put it in the first rank, as it does not succeed well everywhere, and is often shy in flowering. The flowers are larger than those of spectabilis, paler in colour, and in looser clusters, but grows about the same height. It is not grown in nurseries, and here again is an instance of the nurseryman's estimate of value.

P. Toringo is another Japanese species of lesser value than floribunda, but still very pretty. As it is not to be found in nurseries under that name there is no need to dilate upon it, and the same applies to P. Ringo. Both species seem to be in a confused state of nomenclature, and possibly they exist in nurseries under their various synonyms.

P. Schiedeckeri, a recent introduction to our nurseries, promises to be one of the finest of the pyruses. It appears to have affinity with P. spectabilis, and possibly is a hybrid. It has all the beauty of P. spectabilis, and flowers when quite small, only a yard high. Nurserymen are taking it in hand very keenly, and we shall soon see it a common tree. What its mature growth is I do not know. P. baccata yields the various ornamental fruited crabs that are so conspicuously beautiful in gardens during the autumn. There are many kinds of showy fruited crabs now, and all excellent for ornamental planting. The most popular are the Dartmouth, John Downie, Scarlet Siberian, Transcandent, and the new Elise Rathe, a pendulous variety most graceful as a small lawn tree. These crab trees and showy flowered apples are among the many things that the intending planter should bear in mind next autumn. If the garden is large enough then plant them all; if space is limited, then the choice should be P. spectabilis, P. floribunda, P. Schredeckeri, and the Scarlet Siberian Crab. Wherever the apple and pear thrive so will these, and even in soils where apple fruit is inferior these flowering kinds grow well; they never reach perfection on thin soils, on chalk, or in hungry sandy soils, but these can be modified to suit the requirements of such beautiful trees. It is worth the trouble.

Kew.

W. GOLDRING.

AURICULAS AT BRACKNELL.

THE floricultural specialist is a production of these days, and it has come to mean one who, having taken in hand the cultivation of one or two florists' flowers, and proving successful in the matter of producing stock, disposes of his surplus plants and thus gains room in his frames. Such an one is Mr. Charles Phillips, the head of a bank at Bracknell, Berks. The auricula and the carnation are the two flowers to which Mr. Phillips gives his attention, and the prizes he has won with both attest to his ability as a cultivator. To provide accommodation for his plants he has built himself a range of two span-roofed houses, one twenty-five feet in length for auriculas, and one twenty feet for carnations. The line is from north to south, and while there is an abundance of light, there is also ample means of ventilation below and at top, as well as at the sides. There is a walk along the centre of the houses, with stages on either side.

The auriculas, on the occasion of a recent visit, were very gay; the collection is select, and the plants finely grown. It can truly be said, in reference to Mr. Phillips' method of culture, that he appears to get the best possible out of a pot of soil. There is not only a vigorous growth, but they also produce stout stems and magnificent trusses of bloom. One sometimes sees plants with ample leafage and scanty blossoms, but at Bracknell the happy medium is hit—flowers and foliage alike are splendidly developed. Happily for his plants, and especially so at this time of the year, Mr. Phillips is much among them, and the small attentions which have so much to do with the well-being of the auricula are constantly rendered. If anyone wishes to make the acquaintance of the modern, up-to-date florist, who is brimfull of enthusiasm, let him pay a visit to Bracknell at the auricula season, and he will be found there.

Mr. Phillips grows a select collection of show auriculas. You can tick off the names of his green edges on the fingers of one hand; they are Mrs. Henwood, Abbé Lizst, James Hannaford, and the Rev. F. D. Horner. Mrs. Henwood is a very strong grower, and throws up stout flower stems bearing a number of large-sized, brilliant-edged pips. I think that, like the Rev. F. D. Horner, probably one of its progenitors, it can be depended upon. It may be pronounced too large by some of the older school, but it is yet a very strong and reliable variety, and when more widely distributed will be indispensable to a collection of twelve. Abbé Lizst was raised by Mr. J. Douglas, an excellent green, very bright; the corolla of excellent shape. It will be remembered it was a plant of this variety which gained the premier award at the auricula show recently held in London. It throws a strong stem surmounted by a symmetrical truss. James Hannaford (B. Simonite) can be denominated a catch flower. It will sometimes come very good, but oftener indifferent. When it was first shown it was hoped it would prove a green-edge with the quality of pip and constancy of George Lightbody; yet it is unconstant and uncertain. The leading grey-edges at Bracknell are Richard Headley, very fine indeed, grand in growth, truss and quality; Marmion, one of the best and most useful show auriculas Mr. Douglas yet raised; George Rudd, very good indeed; George Lightbody, Dr. Kidd, a good, constant flower, which can sometimes be shown as a white-edge; and the Old Lancashire Hero, still one of the best when in good character. White-edges are represented by Conservative; Reliance (Mellor), which does not open kindly, a fault common to some varieties; Acme; Heather Bell, a somewhat coarse flower, weak in tube; John Simonite; and Mrs. Dodwell, the body-colour of which is often too heavy.

Mr. Phillips has made a hit as a raiser of selfs, his two dark varieties, Miss Barnett, shaded claret or plum, good in all its parts, pip smooth and handsome; Mrs. Phillips, rich maroon, a very striking contrast being afforded by the dark self colour. The golden tube and white paste, also of very fine quality. Black Bess, Heroine, so apt at times to come shaded, and Mrs. Potts, as yet our best blue self, though capable of great improvement. Mr. Phillips also has a yellow self which comes very near to Horner's Buttercup in point of quality. Mr. Phillips means to be a raiser as well as a cultivator, and as the gentle art of raising new varieties of show auriculas does not remain long the possession of one individual, his turn may have come. He diligently fertilizes, and already has young seedling coming on apace. It is with the alpine section that Mr. Phillips has scored such striking successes as a raiser. His varieties are characterised by striking gold centres and massive refined pips. Of his new gold centres the following are very fine: Clara, Pluto, Evelyn Phillips, Miranda, Mrs. Gorton, Mrs. Martin Smith, Dreadnought, Topsy, Bronze Queen, A. R. Brown, Chastity, Jubilee Regina, Katrine, Princess Louise, Messrs. Shaw, Vandyke, and Marian. Of white and cream centres, Gladys, Mrs. Barnett, Sister Mary, and Edith Western.

Hundreds of seedlings of alpines are raised every year from the best varieties. As soon as large enough they are planted out of doors, where they remain until they are large enough to flower, running many risks meanwhile from the incursions of worms and garden vermin, heavy rains &c. But they grow grandly and flower superbly, and as promising varieties display themselves they are duly marked and potted. One realises the glorious freedom of bloom in the alpine auricula when they see the mass of flowers the plants will produce. Potting is done as soon as possible after the plants have gone out of flower. The show varieties and alpine find their summer quarters in cool frames in shady spots. The young stocks growing on from offsets taken in early spring are in the best condition.

Of carnations, Mr. Phillips has some seven hundred pots, including a large number of yellow grounds; and with blooms of these he can hold his own on the exhibition table as with his auriculas. The two pet hobbies with Mr. Phillips are these two florists' flowers; and having a good deal of leisure time, he wisely looks to his garden for pleasant recreation, and finds in his plants companions capable of affording him the highest enjoyment.

R. DEAN.

WORK FOR THE WEEK.

WARM ORCHIDS.

DENDROBIUM phalænopsis Schroderianum will now be growing freely; the roots will be forcing themselves from the suspended pans or baskets searching for moisture; a little help in the way of liquid cow manure will be beneficial, and this may be put underneath the stages and all about the floors several times during the week. The syringe must be used freely several times a day on favourable occasions; by so doing, thrips, &c., cannot lodge about them; besides, the moisture refreshes the plants. Slight shading will be necessary, but the dendrobiums enjoy a certain amount of sun, thus enabling them to make sturdy growths. Ventilation by the lower openings must be given, and the top ventilators used only to keep the house at a reasonable temperature. It is useless to attempt to keep one temperature in this house as used to be the case in growing orchids, and no hard and fast rule is required to succeed well. Guard against dry heat, always check the fires at any time when the weather will allow it, to allow the plants as much natural heat as possible.

Spathoglottis aurea and S. Kimballiana will be commencing to grow, and if potting is required this may be done now, the compost to consist of equal parts fibrous peat and loam, a little leaf-mould, and chopped sphagnum. These thrive well in a warm shady place, grown in pots and kept below the rim to allow for water in the growing season. Aerides that have been imported must be well washed, and suspended upside down along the pathway, or anywhere in a shady place where they can be syringed to encourage root action, before placing them in their pots or baskets, the latter being preferable for the dwarfer growing kinds. Stanhopeas are very irregular in their habit where any stock is grown; some are flowering, others commencing to grow, &c.; as a rule, they are very much neglected, and allowed to grow wild as it were. They ought to be treated individually according to their respective habits. Those that have overgrown the baskets may be divided, supposing they are in a proper state. Those likely to flower will require slight watering, sufficient to keep the bulbs plump until growth appears. Teak wood baskets are required in order to allow the spikes to push their way through, and the right materials to use are rough peat and sphagnum, very few crocks, with openings between; these are well worth growing for their curious type of flower and the odour they give.

The hot rays of the sun we have occasionally will be too much for phalænopsis, and the shading must be put down earlier in the morning when necessary. In addition to the blind outside another one must be nailed up to the rafters inside as a permanency for the season, more especially if lath blinds are used, besides being an additional shade, as a matter of fact, must retain the moisture, always allowing a nice growing atmosphere. The bottom ventilators must be left open night and day with the exception of a wild night. After the inner blind has been nailed up less water will be required; syringing between the cylinders twice a day and damping all round, and a slight spray overhead in the morning, will suffice for a time. Where only a small stock is grown they can be placed in one corner of the house and treated accordingly.

The cattleya house must have a good damping in the morning, and the plants a syringing between the pots and a spray overhead before the hot rays of the sun appear; the floors damped again at noon, and another good damping in the afternoon. This must be done according to atmospheric conditions outside. The temperature will be higher with the weather being warmer—phalænopsis, 70 degrees night; cattleya house, 65 degrees night; intermediate, 60 degrees night. The above will all rise during the day by sun, and ventilation must be given accordingly.—T. STAFFORD, *Tyntesfield Gardens.*

CONSERVATORY AND GREENHOUSE.

CAMELLIAS in pots or tubs which flowered early will have now completed their new growth. It will therefore be necessary to keep the atmosphere of the house they have been growing in somewhat drier, to harden the wood and prevent them starting into a second growth. As the wood and foliage becomes harder less shading will be necessary, and in a few weeks the plants may be arranged in a sheltered nook outside. Although the plants have finished their growth the roots should be still nourished with weak liquid manure or soot water at least once a week, which will assist the flower buds to plump up later on. Azaleas require much the same treatment. Remove the plants to a cool, airy house as they finish their growth, but continue to syringe them freely to keep thrips in check. Gradually expose the plants to more sun and so prepare them for standing in a sunny position when the young foliage is sufficiently firm to stand the full force of the sun. It is always safe to syringe the plants once a week with some weak solution rather than allow insects to appear and then use strong measures to dislodge them. With ericas and epacris excessive care is sometimes practised in giving water and the plants are greatly injured by being too dry. The compost is made very firm in the pots, and it is necessary to water plants several times over before the ball is thoroughly moistened through. If by chance any of the plants have become too dry, the best way to treat them is to plunge the pots in a tub of water for several minutes. Many ericas which are not doing well would more than probably be found to be too dry at the roots if they were turned out of their pots and examined. The plants should be arranged on a bed of ashes or shingle to retain moisture. The worst position, especially at this season, is an open wood trellis or stage. Shade the plants for a short time when the sun strikes them fully. Pinch the points out of the strongest shoots that are taking the lead of others, or draw them towards the rim of the pots so as to give the weaker shoots a chance of gaining strength. What potting is necessary should be completed forthwith, but in potting up young stock be careful not to give them too large a shift, an inch space round the ball being quite sufficient. Peat is the usual compost used, though we have grown the soft wood section equally as well in good loam and sharp sand. Greenhouse rhododendrons frequently fail to flower profusely through overshading. They practically need no shade beyond a slight one just as new wood is being made, which should be dispensed with directly the foliage is fully formed. The wood must be thoroughly hard and ripe, then every shoot will produce bloom. These may be potted almost at any season, but we prefer potting as the plants pass out of bloom, and just as new growth commences. The roots then become thoroughly established in the new compost before autumn.—R. PARKER *Goodwood Gardens.*

THE FLOWER GARDEN.

OWING to dull and cold weather, spring-bedding plants are holding on into them late, and where much summer bedding is done the spring bedders are in the way when the seasons are so late as the present one. Summer bedding-out should, however, by this date be in full swing, and unless under specially required conditions all spring things must be cleared off forthwith if a satisfactory summer display is desired. The recent rains will considerably faciliate the removal of such subjects as pansies and violas, and these should be laid in temporarily in shallow drills in the reserve garden to be attended to in the way of propagation and division later on. Primroses and polyanthuses may be treated similarly, or if time allows, be pulled in pieces now and planted direct into the reserve garden in duly prepared and rather shady borders, at about eight inches asunder each way, where they should make good plants for use again in late autumn. All these transplanted subjects should be supplied with water when necessary. Bulbous plants, as daffodils and tulips should, if it be desired to preserve the bulbs in good condition for next autumn's planting, be lifted with as many roots as possible. and be laid in shallow trenches in the reserve garden, and if here allowed to ripen off naturally, the bulbs will suffer but little from the moving. As soon as the leaves wither and ripen off, the bulbs should be lifted and spread out in a dry cool shed preparatory to cleaning and storing. A method practised here with several beds of yellow jonquils and Narcissus poeticus is to lift the bulbs from the beds, lay them out on mats while the beds are dug, and manured if required, the largest bulbs are then selected and planted in these or other beds in patches of five or six bulbs with the tops twisted together into a knot, at a space of six to eight inches apart each way. Where the beds are to be planted with pelargoniums or similar subjects, these are easily planted between, and when cleared off in the autumn the bulbs have made a good start.

From this date the bedding out of sub-tropical and other somewhat tender plants may be generally undertaken in all southern localities, and in less favourably situated districts a week or so later. A sub-tropical garden or bed should occupy a sheltered position, where plants of such handsome leafage as ricinus and others may be screened from rough winds by belts of trees or shrubs, yet be open enough to receive all sun warmth from south and south-west, this being essential to ensure free growth and finely coloured foliage, otherwise few of these subjects make a satisfactory display. Where palms are employed, the pots should be sunk into the soil and a small quantity of coal ashes or fine rubble placed underneath each pot. A well-grown kentia or seaforthia forms a good central plant in a large round bed filled with sub-tropicals of a lesser growth. Such a bed may be carpeted with a grey-leaved sedum, as S. glaucum, and thinly planted with dark-leaved cannas, with a good palm for the centre. The variegated Dactylis glomerata, violas, and such like may also be used as groundwork for hedychiums, dracænas of the indivisa type, solanums, wigandias, and Ricinis Gibsoni. Other tall-growing subjects are abutilons, Humea elegans, Melianthus major, niciotianas in variety, acacias, grevilieas, New Zealand flax, aralias, and variegated maize; while for association with these as marginal plants, Perilla nankinensis, Centaurea Clementei, C. gymnocarpa, and C. candidissima, Amaranthus melancholicus ruber, Chamæpeuce cassabonæ, and C. diacantha may be used. All bedding plants turned out of pots should be in a moist state when planted, and the soil and roots will be in the best condition for planting, if watered an hour or two previously. The recent showery weather has been favourable for the planting out of frame-raised annuals, and beds filled with seedling of double zinnias, gaillardias, verbenas, petunias, antirrhinums, &c., soon grow away, and may take the place in many instances of pelargoniums and others that have of necessity to be kept under glass for some months. Annual sunflowers should be planted forthwith; the tall growers are effective at the back of herbaceous borders where room can be given. Annuals in variety sown on borders, or in the reserve garden for cutting from, should be thinned out to a few inches apart as soon as large enough to be handled. All dahlias should be planted, and given a mulch of rotten manure.

Where wallflowers are required for spring bedding the present is a suitable time to sow seeds to produce good stocky plants for going out in the autumn. In hot light soils a north border should be chosen for the seed bed. The seeds should be sown thinly in shallow drills drawn out six inches or more apart. As soon as large enough to moue transplant to other borders, allowing a space of nine inches apart each way. The varieties are now numerous. A good dark and yellow is Veitch's Blood Red and Belvoir Castle Yellow; while a pale primrose will be found in Faerie Queen or Primrose Dame. A very early-flowering variety is Sutton's Earliest of All, which blooms in autumn and midwinter, if the weather be not very severe. Campanula calycanthema, C. pyramidalis, and C. pyramidalis alba should also be sown now.—C. HERRIN, *Dropmore Gardens.*

HARDY FRUIT.

WITH genial rains all kinds of hardy fruit will have greatly benefited, as owing to the small rainfall during the winter and early spring the soil was very dry indeed, and insect pests were becoming most troublesome. Unfortunately for the tender kinds of fruit, we have during the past few days experienced very cold weather, the night temperature having been very low, and with cold easterly winds prevalent the growth has been retarded, and in a few instances I have noticed wholesale dropping of fruit. This is to be deplored, as the stone fruits, such as apricots, early peaches, nectarines, and plums are none too plentiful. Doubtless the dropping is influenced by imperfect setting and the cold weather combined, indeed the growers of hardy fruit have a difficult task, as with every promise of success after a poor season a few days bitter weather soon destroys all prospects of a future crop. With a spare crop, and should warm weather follow the weather described, growth will be most vigorous, and here the fruit grower will need to use discretion, as upon the management of the trees now will greatly depend next season's crop.

The production of gross wood must be prevented, and with certain kinds of trees it is an easier matter to advise than to carry out, as in the case of pears and apples, unless there is free extension the roots have too much play and the trees fail to crop if closely stopped and the roots not interfered with for years. On the other hand, at this season much may be done by pinching in preference to the free use of the knife when the trees are more advanced in growth. I find we obtain much better results from our cordon pears and apples by regular stopping from now to the end of June than by hard cutting of young shoots after that date. In stopping young trees one may with advantage remove weakly shoots altogether, as by hard cutting in the winter every small bud produces a shoot. Spur-pruned pear trees on walls are often seen a forest of small, weakly shoots. I am aware there must be enough retained to equalise root action, but with ample fibrous roots such a large proportion of small, weak wood is not conducive to fruit bud formation. I have found a great gain as regards these fruits by thinning the growths at this season; it not only induces fruit spurs to form and mature—the latter equally important as formation of fruiting wood—but the wood made when ripened is able to produce better fruits, and to battle against variable seasons. I see no necessity whatever for letting wall-trees take their chance from now, and allow all the fruit that shows to ripen. Standards are better able to bear heavy crops. I have dwelt upon stopping and removal of useless wood, but thinning of fruits should now receive equal attention. Unfortunately in our case with some varieties we have but little to thin, as our early peaches are very few indeed owing to the severe weather we had at the end of March, whilst the trees were in full bloom and our favourite nectarine, Lord Napier, of which we have a goodly number of trees, suffered badly. On the other hand, Early Rivers passed through the gale uninjured, and this may have been owing to the bloom being a little more advanced. This will become one of the most valuable trees a fruit grower can have, as it is from ten days to a fortnight earlier than others, and what is better it is a splendid grower, and quite at home on different aspects. Apricots are swelling up freely, and there is now no fear of dropping, indeed, as far as my experience goes, dropping is often over-rated, and at times is assisted by allowing the trees to carry too many fruits before they are thinned. Plums and cherries often drop wholesale, and many think it is the natural way for trees to relieve themselves of the crop, but the strain on the trees is so great it will be found that earlier thinning will in a great measure prevent the loss of fruits that are needed for a crop. The final thinning of cherries should not be delayed, as though I am aware the trees will mature most of the fruits they will be much smaller if all are left, and by judicious thinning of wall trees some of the best kinds, such as Bigarreau Jaboulay, Bigarreau Napoleon, and B. Monstreuse de Mazel are very fine indeed, and are a great addition to the dessert, as they come in early and are much appreciated. The cherry will soon begin to colour, and before this takes place I find a liberal supply of liquid manure or a good fertilizer will greatly assist in swelling up the fruits, but to be of service it is best given before the colouring begins ; on the other hand, trees on walls with a rather wide coping should be well syringed before the fruits colour, as in light soils it is almost impossible to keep the trees clear of black fly, one of the worst pests the cherry is subject to, we use Bentley's Quassie Extract on all our wall trees before the stage alluded to.—G. Wythes, *Syon Gardens.*

THE WATER GARDEN.

Shadeloving Bog Plants.

In the shade we might grow by the waterside an equally large number of handsome plants as in the sun, and, though not pretending to give anything like a complete list of them, I will mention a few of the most important.

The bright purple Primula japonica and the deep yellow Primula sikkimensis were mentioned in connection with Enys ; they certainly deserve a place in every garden where a shady sheltered nook by the waterside can be found. The pink Primula Poissoni and the rare yellow Primula imperialis will, no doubt, become equally popular when they are more plentiful and less expensive. Other bright flowers for a moist and shady position are Mertensia virginica, of a beautiful blue ; Spigelia marilandica, red and yellow ; Sanguinaria canadensis, white or pale lilac ; Actinomeris virginica, yellow ; Trillium grandiflorum, white ; and Ourisia coccinea, scarlet. The last named I find does better in stony poor clay soil than in well-prepared peat. Under this section must also be mentioned some of the shade and moisture loving orchids. The exquisite pink lipped Cypripedium spectabile, the yellow lipped Cypripedium pubescens, and several species of habenaria, with flowers of various shades, are most suitable for a shady corner sheltered by rocks, or for a bogbed shaded by other plants. Some shade-loving plants of medium size are ornamental in their foliage as well as in their flowers. This applies to such as Saxifraga peltata, with peltate leaves a foot across, and pink flowers ; Saxifraga fortunei, with shiny leaves on red stems and trusses of white flowers ; Megasea crassifolia, with large leathery leaves and rosy purple flowers ; Podophyllum Emodi, P. peltatum, and Rodgersia podophylla, all of which I have planted by the waterside with great success in various localities.

Dwarf Plants.

Before closing my list of plants for the water garden, I will briefly refer to another section, namely, dwarf plants ; that is to say, plants seldom more than a foot in height. The value of such for carpeting the ground between the taller plants in bogbeds by the side of a pond, either on a large or small scale in a rock garden, cannot be over estimated. The taller and bolder plants can show to perfection only when they are kept a proper distance apart, and without the aid of such dwarf plants the ground between the larger specimens would otherwise often remain bare. But even without the tall plants a very pretty bogbed in the rock garden might be filled by these dwarf subjects alone.

Most suitable plants for trailing close to the ground and succeeding well in the shade are : Linnæa borealis, Pratia angulata, Hypericum nummularium, Gaultheria nummularioides, Erodium Reichardi, Arenaria balearica, Mitchella repens, and the golden form of the well-known Creeping Jenny. Plants slightly taller and requiring no shade are Cardamine trifoliata, Dondia epipactis, with curious yellow flowers ; Parnassia palustris ; Saxifraga azoides, with yellow flowers ; the rapidly spreading Dryas octopetala ; the yellow Chrysogonum virginianum ; myosotis ; and the scarlet Mimulas cardinalis. No bogbed, large or small, should be without large batches of that loveliest of early primroses, Primula rosea, with its brilliant rosy flowers, which in the improved form *(P. r. grandiflora)* are still larger and of a deeper red. Primula farinosa and P. longifolia are also excellent bog plants specially suited for the rock garden, but being rather minute, they should not be planted too near fast-growing plants. If gritty sand or small stones are mixed with the soil we might here also grow large groups of the deep blue Gentiana acaulis. Insectivorous plants, too, might be introduced, and sarracenia, darlingtonia, pinguicula, and drosera in several kinds are often a great success in a bogbed among rocks.

The following require a shady bog : Rhexia virginica, with beautiful pink flowers ; Epigæa repens, white ; Pyrola rotundifolia, white ; Polygala chamæcistus, yellow ; Polygala chamæcistus purpurea, yellow and purple ; Vaccinium vitis ; Idæas minus, with handsome red berries ; Saxifraga hirculus, yellow ; Galax aphylla, with small white flowers and handsome leathery leaves, which turn scarlet in autumn ; and last, but not least, Shortia galacifolia, with bell-shaped white flowers, slightly shaded with rose, and having handsome reddish-bronze leaves.

This somewhat extensive list of plants suitable for growing in a water garden by no means exhausts the number A great many names have been omitted. I have mentioned only what in my own experience have proved to be the very best, and the experience of others might differ to some extent from mine. But I hope to have shown, at least, that we have a truly astonishing number of plants to choose from, which are most suitable for embellishing the water or the waterside in our parks and gardens, and I venture to hope that the hints given may have interested other lovers of the waterside.

Exeter.

F. W. Meyer.

MEMORIES OF BRUGES.

Returning to the City of Bruges from Messrs. F. Sander and Co.'s Nursery, it is a pleasant walk westward to the suburb of Scheepsdaele. After passing the nearest Porte, it is desirable to turn sharp to the left, when one is immediately upon the Rempart de la Porte Marechale ; some distance below lies the sluggish and broad canal, and down to its margin slope the grass-covered ramparts. A good deal of planting has been done along the top of this huge erection, trees and flowering shrubs having been extensively disposed in large mixed clumps or small plantations. Lilacs, philadelphus, berberis, deutzias, and gorse appeared to be the favourite flowering shrubs. Trees of various kinds, principally lime, elm, plane, and poplar have been placed in these plantations so as to produce an effect as early as possible. One could imagine a bundle of from three to eight young trees planted as received from a nursery, and then, after planting, the several stems tied outwards from the root centre to a surrounding triangular or quadrangular wooden support. By this means a good mass of foliage is quickly produced ; but what about the subsequent results ?

Continuing along the pleasant rampart and crossing the railway twice one reaches the Porte d'Ostende. Outside the gateway and across the line of canals a broad road with double avenue opens out, and on either side are to be seen Belgian nurseries of various sizes. A short walk under the leafy lime trees brings one to an unusually extensive nursery frontage, behind which are the home, offices, and extensive glass-houses of M. Vincke-Dujardin. Nothing is more conspicuous as one enters this famous establishment than the enormous quantities of huge bay trees. There is a splendid avenue of the finest specimens lining the central roadway through the nursery, and some of these are old family friends, for they have been in the family not less than one hundred and thirty years. Behind the glass-houses are big armies of fragrant bays, standards and pyramids, in a variety of sizes, all admirably cultivated, and in the best of health ; here the tubs are sunk into the light soil, and so the drying influence of the sun and wind is kept from the roots to a large degree. Looking at these specimens, it is difficult to estimate the vast amount of time and patience that has been expended upon their production, for the watering, housing, and pruning are items that must require much care and labour.

The houses here are built upon the plan that obtains in all the larger Belgian nurseries, and one that is now extensively adopted at home and in America. Viewing a block from outside one estimates the number of houses it contains by the number of spans that appear ; but enter, and the whole is but one huge glass-house. This method of construction results in a great saving of expense in the matter of brickwork, for the numerous furrows are supported only by light iron uprights, and walls form an enclosure to the whole. M. Vincke-Dujardin has gone one better than many nurserymen in this system of building, for he has in some instances a big central house several hundred feet long, more lofty than all the others, and containing the tallest specimen palms ; into this fine structure, or rather from it, run lower houses along its length, and from these there is no means of egress save through the central structure. I did not count the smaller houses, but probably there are ten or more running from either side of the larger one. This system ensures equable temperature, if such is desired ; it allows ventilation to be afforded with a great degree of accuracy, and entirely prevents cold draughts. Rather heavy shading, and a water supply that seems to be admirably suited to plant cultivation, are other items that assist in the production of free growth and handsome plants.

M. Vincke-Dujardin has become famous for his odontoglossums, both for the admirable forms of the more popular species he has distributed, and the wonderful robustness of all the plants he cultivates. Comparatively speaking, the odontoglossums at Scheepsdaele grow as vigorously and freely as rhubarb, making fine fat pseudo-bulbs, stout purple-tinted foliage, and producing thick spikes of great size, that carry large substantial flowers. It is not many years since that Mr. Vincke-Dujardin accidently discovered that the cool orchids succeeded remarkably well at his nursery ; following this discovery, and at the advice of a well-known English market grower, he purchased odontoglossums extensively, taking care to obtain plants from the very best districts. They grew well, and had to be divided to keep them "sizeable." The varieties of O crispum turned out to be of the very best, and it is a fact that most of the very fine forms of this beautiful odontoglossum that have made their appearance in Europe of late years, have passed through M. Vincke's hands.

Odontoglossum crispum, O. Pescatorei, O. triumphans, O. luteo-purpureum, O. Halli, and O. cirrhosum are here grown in enormous quantities, and their liking for the conditions that prevail is seen in the arching spikes and beauteous blooms. Rarities are not wanting amid so extensive a collection ; rose coloured, yellowish, and spotted form of O. crispum abound, and at the time of my visit there were not a few examples of O. Wilckeanum, O. Ruckerianum, O. sceptrum, and O. Andersoneanum flowering profusely. The attractive Miltonia vexillaria is equally at home in this interesting nursery, and flowers with a freedom not often seen in our islands. Cattleyas, chiefly of the labiate section, fill several houses, the typical C. labiata being present in fine condition. Lælia purpurata promised grandly, and there were fine batches of the popular L. anceps. Vandas occupy considerable space, as also do the cypripediums, the latter flourishing in a manner that would excite the envy of all ardent amateurs. M. Vincke-Dujardin has demonstrated that the species of orchids he grows do not deteriorate under cultivation, for he divides and re-divides his plants as necessary, so as to retain stock of good forms.

The anthuriums are a fine sight when fully flowered, for not only do they give evidence of extremely high cultivation, but there are so many seedlings and hybrids flowering that the variety is charming. Here, as in other Belgian nurseries, a great work is going on in the raising of seedlings of A. Scherzerianum and A. Andreanum, with a view to improvement of form and an increase in the shades of colour. Bromeliads are very attractive, for every plant is a perfect specimen, and only the very best species or hybrids are cultivated. Palms are to be seen everywhere, from the tall specimens of Cocos plumosus, Arecas, and Kentias, that reach to the roof in the central houses already referred to, down to seedlings not yet potted. The quantities of the two principal Kentias, of Latania rotundifolia, cocos of sorts, arecas, and rhapis, are such as fill one with astonishment ; they are clean, handsome, saleable plants, such as M. Vincke-Dujardin has a wide reputation for, and, in spite of their numbers, they will not long remain upon their present owner's hands.

Servator.

EXHIBITIONS AND MEETINGS.

ROYAL BOTANIC SOCIETY OF MANCHESTER.

A MAGNIFICENT show was held at the Old Trafford Botanic Gardens, Manchester, during the whole of Whitsuntide, and, had it not been that the opening day here was the closing day of the Temple Show, Manchester would undoubtedly have seen its finest exhibition up to date. As usual, orchids were the great feature, but new plants, clematis, carnations, rhododendrons, calceolarias, violas, &c., were plentiful, and added to the interest of the display. Everything in the way of arrangement was as nearly perfect as may be, under the able guidance of Mr. P. Weathers, the curator and secretary of the Royal Botanic Society.

There was a keen competition in the class for a collection of orchids, Mr. J. Cypher, Cheltenam, Mr. Robson, Altrincham, and Messrs. Heath and Son, Cheltenham, gaining the awards in order as mentioned; not only did Mr. Cypher have a fine collection of the best orchids, but the group was tastefully arranged. In the amateurs' class for a collection of orchids, E. Ashworth, Esq., Harefield Hall, Wilmslow, secured the chief award with a beautiful set of plants in which particularly good forms of Lælia purpurata, Cattleya Mossiæ, and C. Schroderiæ were noticeable; tasteful arrangement and high cultivation characterised this collection. Mr. A. Warburton, Haslingden, followed with a good group in which some exceptionally lovely forms of Cattleya Mossiæ appeared. Mr. Ashworth also came to the front for a collection of ten specimen orchids, his best plants being Odontoglossum Vuylstekeanum, Lycaste Skinneri, and Cattleya Skinneri alba; this was an open class, and Mr. Ashworth succeeded in beating Mr. J. Cypher, of Cheltenham, and Mr. T. Harker, of Didsbury. The other orchid class was for a collection of cattleyas and lælias, and here the first prize was ably won by Mr. Johnson, gardener to T. Statter, Esq., Stand Hall, Manchester, who staged a rich collection of handsome forms, all highly cultivated; Mr. D. Gilmour, Sandygate, Sheffield, came second, and Mr. J. Cypher third.

For ten stove and greenhouse plants in flower the only exhibitor was Mr. J. Cypher, who staged splendid specimens of Pimelia spectabilis, Erica Cavendishi, Clerodendron Thomsoniæ, &c., &c., all freely flowered and fully furnished. Mr. Wilkes, gardener to Miss Lord, Ashton-on-Mersey, was a most successful competitor, winning first prizes for a group not exceeding one hundred square feet, for twelve calceolarias, six caladiums, one specimen stove foliage plant, for one flowering stove plant, for six stove and greenhouse plants, for greenhouse foliage plants, and for greenhouse flowering plants, and for a single fern. Mr. J. McIntyre, gardener to Mrs. G. Pease, Darlington, led the way for a group arranged on a space of two hundred square feet; this consisted of palms, crotons, ferns, orchids, and flowering plants in season, all arranged with the taste and lightness that always characterises Mr. McIntyre's exhibits; Mr. Wilkes second. Mr. McIntyre also secured the chief awards for six fine foliage plants with a handsome set of crotons and palms, for ten exotic ferns, for eight table plants, and for six adiantums. Mrs. Kerr, Whalley Grange, and Mr. W. H. Thorley, Chorlton-cum-Hardy, were both successful amateur exhibitors.

Messrs. R. P. Ker and Sons, Aigburth, Liverpool, won first prize for a group of miscellaneous plants arranged for effect upon a space of two hundred and fifty square feet; this was a splendid exhibit, and deserved all the eulogiums passed upon it; Mr. A. J. Bruce, Chorlton-cum-Hardy, was a good second. The only exhibitors in the class for ten hardy ferns were Messrs. W. and J. Birkenhead, Sale, Manchester, who had a most interesting set of handsome forms.

NON-COMPETITIVE EXHIBITS.

The trade growers came out well on this occasion, and provided a good exhibition themselves. Messrs. J. Veitch and Sons, Chelsea, contributed a collection of exceptionally fine orchids, either hybrids or especially fine forms of well-known species; their Lælio-cattleya Endova var. Madame Albert Hye is a grand hybrid between Cattleya Mendelli and Lælia purpurata; L.-c. Ascania, L.-c. Wellsiana, and Lælia purpurata formosa were also very handsome. Messrs. F. Sander and Co., St. Albans, sent their huge specimen of Dracæna Sanderi, together with several new palms, including Licuala Jeanenceyi, figured in our issue of May 28, and a group of the novel Acalypha Sanderi, also figured in our issue of that date. Messrs. J. Cowan and Co., Liverpool, staged odontoglossums, cattleyas, lælias, and cymbidiums in variety, making an attractive exhibit. Messrs. B. S. Williams and Son, Holloway, put up a good collection of orchids and other plants; Messrs. Fisher, Son, and Sibray, Sheffield, showed crotons and orchids in first-rate condition; Messrs. Charlesworth and Co., Bradford, contributed a collection of orchids, which included not a few new and handsome hybrids. Mr. Keeling, Cottingley, was also an exhibitor of orchids.

An exceedingly bright group of well-grown calceolarias came from Messrs. Sutton and Sons, Reading, who also showed a collection of early peas representing the varieties they have distributed. Violas, calceolarias, &c., were tastefully disposed by Messrs. W. Clibran and Son, Altrincham, while Messrs. Dicksons, Chester, were represented by a choice collection of hardy herbaceous flowers, auriculas, pansies, violas, and Japanese maples. Clematis were shown in superb condition by Messrs. R. Smith and Co., Worcester. Rhododendrons from Mr. J. Waterer, Bagshot, Surrey, were greatly admired, but those planted out were scarcely at their best.

Gold medals were awarded to Messrs. Sander and Co., Messrs. Sutton and Sons, Messrs. Fisher, Son, and Sibray, Messrs. J. Veitch and Sons for Lælio-Cattleya Endova var. Madame Albert Hye; and to Sir Trevor Lawrence, Bart., for Cypripedium Olenus Burford Lodge var. Silver medals were awarded to Messrs. Charlesworth and Co., Messrs. J. Cowan and Co., Messrs. B. S. Williams and Son, Mr. A. J. Keeling, Mr. J. Waterer, Mr. A. J. Bruce, and Messrs. R. Smith and Co.

The luncheon was presided over by T. Slatter, Esq., who heartily welcomed Sir Trevor Lawrence, Bart., who was paying his first visit to Old Trafford. Mr. Slatter alluded to the great help the society had derived from the Press, while Sir Trevor expressed his admiration for such a magnificent show. The other speakers were Professor Leo Grindon, Mr. Tait, Mr. Owen Thomas, and Mr. Gribble, all of whom spoke in high terms of the Whitsuntide show of 1898.

COUNTY OF GLOUCESTER AND CHELTENHAM HORTICULTURAL SOCIETY, May 28 and 30.

THE first show for the season was held at the Montpellier Gardens, Cheltenham, on the above dates, and proved a floricultural success. The show was opened under sunny skies, and a goodly attendance resulted, but on Monday the additional attraction of athletic sports drew a very much larger company into the grounds. The schedule provided forty classes, and attracted an average of three entries each.

STOVE AND GREENHOUSE PLANTS were unusually good and numerous, Mr. J. Cypher, Queen's Road, Cheltenham, being in splendid form with his many specimens, he securing the first prize in the open class for ten specimens, the most striking being Azalea Cedo Nulli, six feet high and through; Anthurium Scherzerianum Wardianum; Ericas Cavendishi and venticosa manifica, a noble pair; E. v. albo tincta, five feet through, a perfect mass of white bloom; Clerodendron Balfourianum, and a marvellously grand specimen of Stephanotis floribunda; Mr. W. Vause, Royal Leamington Spa, second, his premier specimen being a noble example of Erica ventricosa grandiflora; Mr. G. W. Marsh, gardener to T. P. W. Butt, Esq., Arle Court, third, having among other good things a fine Anthurium Andreanum, Azalea magnifica, and Dendrobium fimbriatum, the last named being premier in the amateur class for six specimens.

The groups for effect, occupying three hundred superficial feet, were simply charming arrangements, Mr. Cypher leading, with Mr. W. Vause second. Pelargoniums, show and decorative, were well represented by five collections; for a group, Mr. Cypher, Mr. W. Lusty (gardener to Colonel Rogers), and Messrs. Heath and Sons shared the awards; while for half-a-dozen varieties Mr. Rea (gardener to Mrs. Southwood) and Mr. Lusty divided the honours, with brilliantly-bloomed plants. The show of azaleas in the open class was a bright mass of colouring, the plants of full size, fresh, and densely-bloomed, Mr. Cypher, first, with Mr. G. W. Marsh, second; the latter leading in the amateur division, with Mr. Lusty second. The groups of orchids proved most attractive, the visitors lingering round denoting the lovely forms and colours of finely-developed lælias, cattleyas, dendrobiums, cypripediums, odontoglossums, &c., Mr. Cypher filling the place of honour on the one hundred feet space; while for fifty feet, G. F. Moore, Esq, Bourton-on-the-Water, was a good first, Mr. G. W. Marsh, second. Tuberous begonias were presented in variety, Mr. Lusty leading, he also secured the card for a group of well-grown gloxinias. Pansies in pots in ten varieties made a nice break among the larger plants, Mr. R. H. Smith (assistant secretary) being placed first for a dwarf-grown lot, with Colonel Thoyts, second. Herbaceous calceolarias (in dozens) as exhibited by Mr. Lusty and Mr. Cypher, denoted a very excellent strain; and the only other class of plants was for a group of foliage and flowering subjects, Mr. G. W. Marsh taking the card.

CUT FLOWERS though not forming a large feature were most interesting. Mr. W. Lusty securing the honours for eighteen trusses and a dozen tea roses; herbaceous perennials were grand bunches from Messrs. Cypher, Heath, and Son, and W. Vause; Mr. G. W. Marsh, and Mr. R. H. Smith sharing the honours as amateurs. Table decoration, a new feature here, were very tastefully disposed, Rev. J. P. Davies, securing the card over the head of Mr W. Vause; Messrs. Pates and Sharpe, Bayshill Nursery, led in the class for a bride's bouquet, with Miss Smith second, and Mr. W. Vause third.

FRUIT was a small show but fairly meritorious, Colonel Arbuthnot, was placed first with black and white grapes with Black Hamburg and Foster's Seedling; Mr. G. W. Restall led with a dish of strawberries and ten fruited pots of the same; and Messrs. F. Taylor and W. Lusty shared the awards for peaches.

VEGETABLES were fairly numerous and of good quality for a cold damp season, F. H. Wiggins, Esq., taking the cards for a collection of six kinds; a special prize for a similar number of dishes, firsts for cucumbers, asparagus, potatos, French beans and tomatos, wonderfully good for May; Mr. F. Taylor leading for four dishes, and for mushrooms and cauliflowers.

GOSFORD HOUSE GARDENS.

THE visit of the Scottish Horticultural Association to Gosford House, the seat of the Earl of Wemyss, took place a few days ago, when some seventy members joined the president and secretary, travelling by special carriages to the chief entrance at Langniddry, where they were met by Mr. Cook, the courteous head gardener. From thence a fine carriage road, fringed and belted with trees, proceeds for two and a-half miles through woods and fine parks to Gosford House. Here the party was met by Mr. Connor, the factor of the estate. The park embraces some 500 acres, or, including the woods, which abound in game, some thousand acres. Passing through a fine Italian garden, with its massive steps and terraces, the party were met in the marble hall and shown through the picture galleries by the housekeeper. Gosford House is full of the best works of the old masters, and few of the visitors seemed prepared for the great artistic feast before them in the works of Reuben, Rembrandt, Titian, Joerdans, &c., &c., &c. Refreshments were served in the dining-room, and Mr. Todd, in happy and suitable language, conveyed the hearty thanks of the association to the Earl and Countess of Wemyss, through Mr. Connor, for their kindness and hospitality. Mr. Connor bade the society welcome to Gosford in their names, and told them that Mr. Cook had still a great deal more to show them.

The terrace gardens were aglow with wall flowers in two colours—dark purple and soft gold. A good feature was that of several permanent beds of American and other shrubs in the Italian garden. One of the largest of these was filled with Golden Queen holly; then a row of Rhododendron Watereri, edged with a band of Berberis Darwini. Corresponding beds were furnished in pairs—thus, two of Pernettya mucronata edged with dwarf Golden Box; two of Olearia Haasti Andromeda floribunda edged with Alyssum saxatile; two of Skimmia japonica edged with Cotoneedged with Euonymus radicans; two of Skimmia japonica edged with Cotoneaster microphylla. Excellent and liberal use are also made of the golden variegated variety of the dwarf Juniperus sabina. Going towards the pleasure grounds, which consist of some twenty-three acres, some seven acres being water in the form of beautiful lakes, we pass the mound glowing with bright Alpine plants, and the old house which has long been clothed with ivy, Virginian creeper, honeysuckle, clematis, &c. The shrubberies contain a fine collection of flowering shrubs, flowering and other trees with blocks of herbaceous flowering plants and bulbs between. There are also fine specimens of coniferous and other trees, as cedars, Douglas's fir, spruce, Abies morinda, Pinus ponderosa, &c., with catalpas tulip trees, Pyrus sorbus, thorns, and some rhododendrons worthy to rank as trees, being some 18 to 20 feet high and through, in brilliant blossom. The walks, outlines, and furnishing of the lakes, and the delightful green of grass add ever new and fresh charms to the grounds at Gosford.

The kitchen gardens cover an area of some eight acres, and are surrounded with walls about 12 feet high, divided again by a central wall; the walls are well furnished with fruit trees nicely trained, and promising good crops These mostly consisted of apricots, peaches, plums, pears, apples (cordons), and cherries, mostly Morellos. The healthfulness of the fruit trees generally and the excellent appearance of the crops of bush and standard fruits was generally remarked. Salading and vegetables of all kinds were in fine condition. There are some fine vineries at Gosford, and of these four are in one range 140 feet long, 15½ feet high at the back, and 14 feet wide; three peach houses, two being in one range 150 feet long, 14 feet high at the back, and 10 feet wide; and two fig houses 90 feet long, 16 feet high, and 14 feet wide. Besides these there are a range of forcing houses in six divisions filled with melons, tomatos, cucumbers, French beans, and strawberries. A nice stove for palms, ferns, crotons, caladiums, and other decorative plants is provided. Fine batches of Malmaison and other carnations, and zonal pelargoniums, sweet peas, ivy-leaved geraniums, and chizanthus pinnalus for cutting, &c., were seen. Some ranges of useful pots for forcing potatos, &c., and growing violets in winter form useful adjuncts to this department. There is also a useful house for forcing roses, the following being the more prominent varieties, Maréchal Niel, Gloire de Dijon, Belle Lyonnaise, Safrano, Souvenir d'un Ami, Homeré, Marie Van Houtte, Fortune's Yellow, and Cheshunt Hybrid.

The vineries and other fruit houses contained rods and trees in robust health, and carrying good crops. The first vinery contains Black Hamburgh and Foster's Seedling; the second, Muscat of Alexandria; third, Black Hamburgh; fourth, Lady Downs, Gros Maroc, and Alicante; fifth, Black Hamburgh, Gros Colmar and Gros Maroc. Varieties of peaches and nectarines in the early house were: Early Louise, Royal George, Alexandra Noblesse, Grosse Mignonne peaches, and Lord Napier nectarine; second house, Stirling Castle; third, Royal George, Barrington, Noblesse, Walburton Admirable, Late Admirable, Pitmaston Orange and Pine Apple. Figs: Brown Turkey and White Marseilles.

Nothing could exceed Mr. Cook's courtesy and kindness; and, before leaving, Mr. Todd expressed in fitting terms the feelings of all present, as to the very pleasant and instructive character of the society's visit to Gosford. D. T. F.

THE WEATHER DURING THE WEEK ENDING MAY 28, 1898

The mean reading of the Barometer during the week at Greenwich was 29·68 inches, and that of the Thermometer 54°·7, the latter being 0°·9 below the week's average in the 50 years 1841—90. The direction of the wind was easterly, the horizontal movement of the air being 28 per cent. below the week's average in the 16 years 1860—75. The duration of registered bright sunshine in the week was 37·0 hours. The measured rainfall amounted to 0·40 of an inch.

Belgian Fruits and Vegetables find a ready sale in this country, especially plums, cherries, greengages, and pears; so it is not surprising that our imports of these from the busy little continental country amounted last year to nearly 50,000 tons. During the same period not less than 752 tons of living plants, chiefly palms, araucarias, Otaheite oranges, azaleas, and dracænas were exported to Great Britain from one district—that of which Ghent is the centre.

ANSWERS TO CORRESPONDENTS

Editorial communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, &c., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning change of dates.

Caterpillars on Plum Trees.—A. S. Horley: The little black-headed caterpillar belongs to a species of Tortrix, and is a voracious feeder. If you have a powerful supply of water, an easy method of clearing the trees would be to hose them. Failing this, make one of the tobacco and soft soap or quassia and soft soap mixtures so frequently prescribed in these columns, and wash the trees with it by means of a garden engine or syringe. Lime and soot spread beneath the trees would serve to settle falling caterpillars.

Moss on Fruit Trees.—M. B., Jarrow: We have received the letter, but not the specimen referred to. Judging from your remarks we feel sure that it is lichin and not moss that is damaging the fruit trees in the Irish garden mentioned; whether it be moss or lichen it matters not, as both are great pests in moist localities, especially such as are under the influence of the westerly winds blowing in from the sea. Both should be got rid of as soon as possible, though little can be done to make an effectual clearance until late autumn and winter. Any trees that show signs of suffering should have the moss or lichen removed as far as possible by scraping and scrubbing the trunk and stems, taking care not to injure the bark. If the soil is poor, and moss and lichen are usually indicative of either poor or badly drained soils, add the necessary manures to render it fertile. If the land is very moist, then see that it is suitably drained, and in addition, if at all heavy or peaty, give a good surface dressing of lime, and gently fork it into the ground. In the winter when the leaves have all fallen from the trees the time and opportunity for effectual treatment will arrive; it will then be necessary to scrape and scrub the trees and branches where possible, moistening these with a strong soda and soft soap solution. After this give the trees a spraying with a

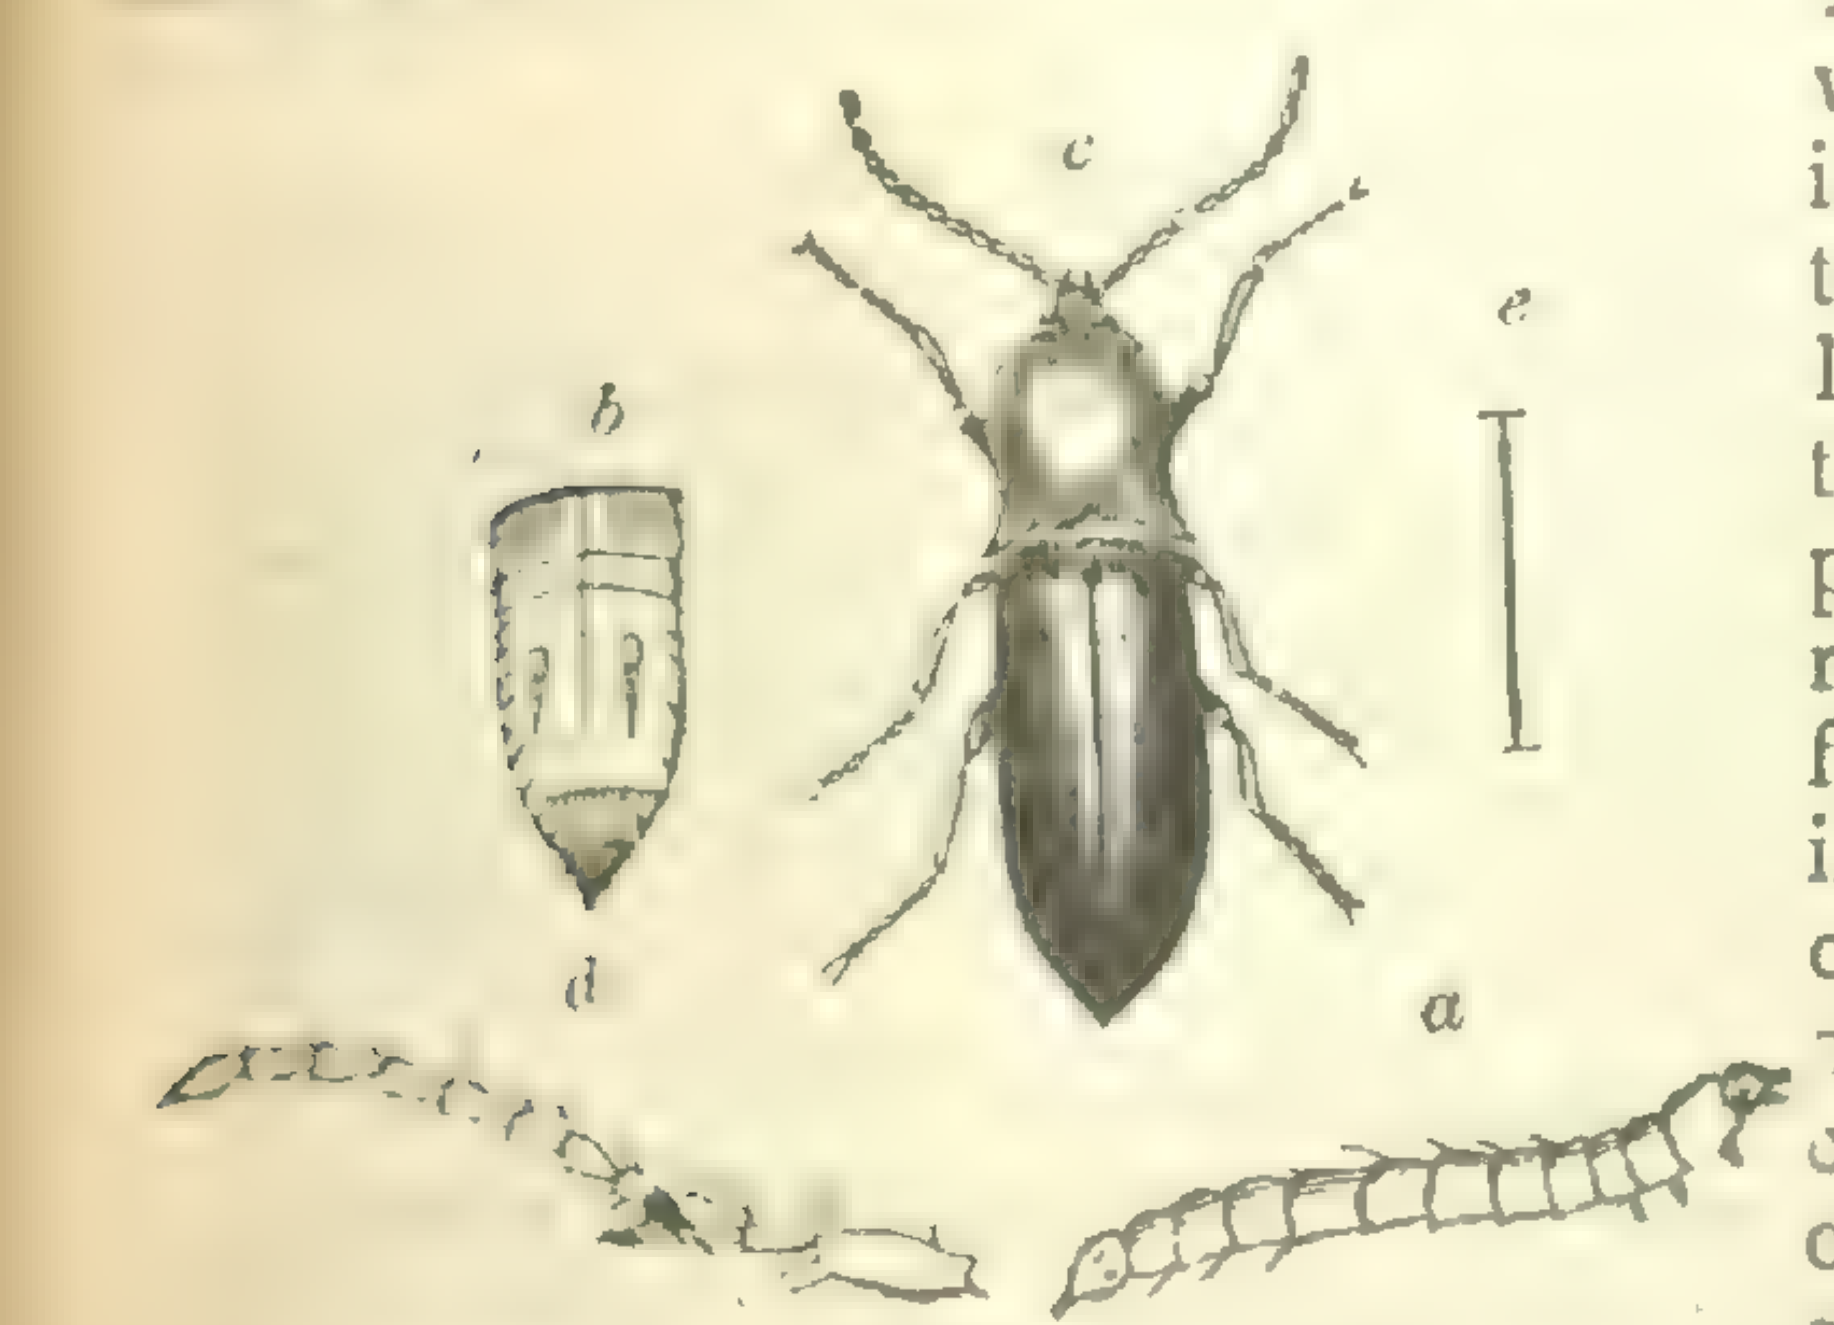
WATKINS & SIMPSON.

PROTECT your Gardens.—Garden Netting for protecting Fruit Trees, Seed and Strawberry [illegible] &c. Inch mesh Tanned Water[illegible], 100 yds. by 1 yd., [illegible] 100 yds. by 2 yds., 50 yds. by 4 yds., or 25 yds. by [illegible] each, carriage paid; sent on approval, and compare it with some rubbish advertised. Lawn Tennis Court Boundary Netting, corded top and bottom, 100 yds. by [illegible] 16s. 6d., carriage paid.—ABBOTT, Net [illegible]

tion of caustic soda and crude commercial potash. These have to be mixed carefully and used with gloved hands. If you write us later we will give you full directions as to the winter cleansing. At present do all you can to assist the trees. Let us know what kind of soil the trees are growing in. With regard to the cherry tree, the damage was, no doubt, due to frost and extreme cold wind; whether it could have been prevented we are not in a position to say. It is a difficult matter to protect trees unless they are trained to a wall or fence.

Malformed Rose Flower.—Cycle, Bowdon: In the peculiar flower sent the lower part of the floral axis has become elongated somewhat. The two petaloid leaves below the calyx and the outer segments above it show an intermediate condition between the foliaceous leaves and the floral ones, showing that there is a tendency on the one hand to assume floral characteristics, and on the other to revert to the original green and foliaceous condition. It is not often that so well conducted a rose as Maréchal Niel produces such a curious bloom as the one you sent us.

Click Beetle and Wireworm.—F. E. S., Chipping Norton: You are quite right; the wireworm is the grub stage of a click-beetle (Elater Lineatus). The beetle is blackish, and its shape is well-shown in the accompanying cut; it deposits its eggs either in the soil close to a plant or in the sheaths of the leaves of cereals. Thus, as soon as the grubs are hatched out, they have plenty to feed upon. Wire worms remain in the grub stage for about four years ere becoming transformed into the beetle stage. One of the commonest and most effective methods of capturing wireworms is to place cut potatos a little below the surface of the soil; these act as traps, and should be frequently examined, and all worms caught should be dropped into a pail of extra strong brine. A piece of stick, eight inches long, stuck into the potato will serve to lift the trap, and also readily indicate its whereabouts.



Wireworm and Click Beetle.
a. Wire Worm; *b*. caudal joint magnified; perfect beetle; *d*. antenna; *e*. length of beetle.

Soil for Hardy Rhododendrons.— F. R., Bognor: It has been proved beyond all doubt that hardy rhododendrons will grow and flower freely in other than peaty soils, so it is not always absolutely essential to remove the natural soil and import peat for them. The one great essential for rhododendron culture is absence of lime in the soil. This ensured, the next question is good drainage, for while the rhododendron requires watering in hot summers, owing to its surface rooting propensity, it hates to be waterlogged or have its roots kept wet throughout autumn and winter. Follow these conditions with a compost of peat, if it is handy, always, and for choicest specimens, using good loam and leaf soil, if peat be absent. Sandy peat is the best rooting medium, but the results from good loamy soil and leafmould, with the addition of dried cow manure, are first-rate. Spring is the best time for planting.

Damaged Chrysanthemum Leaves.—W. H., Lincoln: The leaves have evidently suffered from a severe chill, such as would follow from exposure to frost or keen east wind, when the plants had not as yet become properly hardened. Somewhat similar results would follow the application of an insecticide too strong for the tender tissues, or too heavy fumigation when the foliage was damp and tender. We find no trace of insect or fungoid attack upon the specimens sent. In the case of the grapes sent, there has been a cold current of air passing up under the vines; perhaps a side ventilator has been inadvertently opened.

Crops Under Tomatos.—A.L., Leicester: In such a small house it will not be wise to attempt the cultivation of any other crop under the tomatos. If you are but just planting the tomatos then there are many pot plants that might be allowed standing room for a while. Successive batches of gloxinias and tuberous begonias are not infrequently brought on in such houses, but, as a rule, where this is done there is a greater breadth of border than you have, and so there is little fear of the tomatos experiencing excessive moisture at the roots. Melons will do no good; vegetable marrows will succeed best out of doors, and the alpine strawberries need an open position where, during the autumn, they may be covered with frames, or, at least, with lights, should the weather be inclement.

Names of Plants.—C. T., Brecon: Genista hispanica.

A. S., Horley: 1, Anagallis arvensis; 2, Lycopodium annotinum; 3, Nephrolepis cordata; 4, N. exaltata.

J. P. N., Enfield Lock: Triteleia uniflora.

E. J. C., Croydon: The specimens were packed in a very unsatisfactory manner, and the pad of wet moss put in the canister on top of the little heap of specimens served to damage them considerably, both by crushing, and by extracting the colour from the flowers. A box is much better than a canister, as in the latter specimens are difficult to remove. So far as we can judge, the specimens were Selaginella Mertensi, Abutilon Thomsoni, Cattleya guttata, Dendrobium Jamesianum, and Trichopilia suavis. If you have duplicates send again.

H. S., Warminster: Muscari comosum.

GARDENING ENGAGEMENTS.

Mr. R. Weller, who for eleven and a half years was head-gardener, and latterly steward as well, at Glenstal Castle, Murroe, Limerick, has been engaged as steward and head-gardener to Captain Greer, Crotonstown, Newbridge, co. Kildare.

Mr. W. Jennings, late of Wexham Park Gardens, Slough, has been appointed head-gardener to R. Harvey, Esq., Dundridge, Totnes, Devon.

HARDY MINERS TOIL LONG AND HARD in the bowels of the earth to bring forth precious gems and metals for the use and pleasure of their fellows. In many parts of the world the pick and shovel have struck the first blow of civilisation. Holloway's Pills and Ointment have been potent factors in the quick march of progress, for they have given the armour of good health and strength to travellers both by sea and land. They protect the system from attacks of disease, even in climates where its influence is fatally felt. During the present hot weather, when stomach and liver complaints, diarrhœa, dysentery, &c., are liable to attack anyone, these remedies will be found simply invaluable.—[Advt.]

Fancy Tomatos.—A tomato grower, even on the largest scale, is scarcely human if he has not the desire to try something new, on however small a scale. Then, if he is an eater of tomatos, he will also desire to taste something out of the common. The yellow tomatos we have grown for years, and have had a moderate amount of success with all of them. This time we are growing one sent as Golden Queen—a good grower, fair setter, and with fruit above the usual size, of which I enclose you a bunch. These, though not strictly on the market, sell freely at the shops. Growing side by side with other red varieties, I see little difference in the matter of weight crops under the same conditions. Peach Blow is also doing equally well, and very pleasing is its shade of colour, but I have not yet tasted it. These two varieties are planted out in narrow borders with vines.—STEPHEN CASTLE, F.R.H.S., *Bottesford Vineries, Notts.*

ENGAGEMENT FOR THE ENSUING WEEK.

AUCTION.

FRIDAY, JUNE 10.—Imported and Established Orchids, Protheroe and Morris's rooms.

THE BEST GUIDE to the garden for the whole year is the "Gardening Year Book," containing practical articles on the cultivation of Flowers, Fruit, Vegetables, &c. Price 1s. "Gardeners' Magazine" Office, 4, Ave Maria Lane, London.—[ADVT.]

MARKETS.

Covent Garden.

TRADE is somewhat quiet after the holidays, but the moderate supplies of fruit and vegetables meet a fair demand at moderate prices.

FRUIT.—Tasmanian apples, 8s. to 16s. per case; English grapes, 1s. 6d. to 3s. 6d. per case; Jersey, 1s. 3d. to 2s. per case; Belgian, 1s. to 1s. 6d. per lb.; oranges, 15s. to 20s. per case; Jaffa, 9s. to 12s. per box; pineapples, 2s. 6d. to 5s. per pine; bananas, 5s. to 9s. per bunch; gooseberries, 3s. 6d to 4s. 6d. per sieve; French cherries, 5s. 6d. to 7s per half-sieve; strawberries, 2s. 6d. to 3s. per gallon basket; French apricots, 1s. 6d. to 2s. per box.

FLOWERS.—Arums, 3s. to 4s.; carnations, 1s. to 3s.; eucharis, [illegible]; gardenias, 1s. to 3s.; Lilium Harrisi, 3s. to 4s.; tea roses, 6d. to 1s.; pink roses, 3s. to 6s.; red roses, 2s. to 4s.; cattleyas, 6s. to 9s.; Odontoglossum crispum, 1s. 6d. to 4s.; and tuberoses, 1s. to 1s. 6d. per dozen blooms; Adiantum cuneatum, 4s. to 8s.; marguerites, 2s. to 4s.; narciss, various, 1s. to [illegible]; tulips, 3s. to 6s; mignonette, 2s. to 4s.; pelargoniums (scarlet), 4s. to [illegible]; wallflowers, 2s. to 3s.; polyanthuses and cowslips, 1s. to 1s. 6d.; bluebells, 9d. to 1s.; and violets, 9d. to 3s. 6d. per dozen bunches; azaleas, 6d. to 9d.; stephanotis, 4s. to 6s.; lily of the valley, 6d. to 1s.; white gladiolas, 6d. to 9d; and pelargoniums, 4d. to 6d. per dozen sprays; bouvardias, 6d. to 8d.; white lilac, 3s. to 4s. per bunch.

VEGETABLES.—English tomatos, 6d. to 9d. Jersey, 5d. to 6d. per lb.; Canary, 3s. 6d. to 4s. 6d. per case, 10d. to 1s. 4d. per tray; Egyptian onions, 6s. to 7s. per cwt.; English spring, 1s. 6d. to 2s. 6d. per dozen bunches; asparagus, 9d. to 4s. per bundle; lettuce, 6d. to 10d.; cos lettuce, 1s. 6d. to 2s.; endive, 1s. 3d. to 1s. 6d.; cucumbers, 2s. to 4s.; cauliflowers, 1s. to 2s. per dozen; rhubarb, 2s. to 3s.; radishes, 6d. to 9d. per dozen bundles; new carrots, 4s. to 5s.; turnips, 5s to 6s.; parsley, 1s. 6d. to 1s. 9d.; mint, 4s. per dozen bunches; mushrooms, 6s. to 8s. per 12 lb.; green peas, 2s. 3d. to 2s. 9d. per flat; French beans, 3d. to 4d. per lb.; broad beans, 4s per flat; Canary potatos, 10s. to 12s. per cwt.; Lisbon rounds, 5s. to 6s. per box; Malta round, 8s. to 10s. per cwt.

Borough Potato Market.

New potatos arrive in larger quantities, and are cheapening; owing to the small stocks of old these maintain their prices. Old—Dunbars, 130s. to 140s.; Scotch Magnums, 120s. to 130s.; Bruce, Main-crop, Sutton's Regents, Reading Giants, and Saxons, 110s. to 120s. per ton; Belgians and Germans, 5s. to 5s. 6d. per bag. New—Maltese rounds, 7s. to 8s.; Teneriffe kidneys, 8s. to 9s.; St. Malo 11s. to 12s.; Jerseys, 13s. to 14s. per cwt.; Lisbon rounds, 5s. to 5s. 3d. per box.

THE SEAT OF THE MARQUIS OF NORTHAMPTON.

THE MARQUIS AND MARCHIONESS OF NORTHAMPTON.

Photog. by J. Russell and Sons.

SITUATE in a charming position overlooking the wide-spreading valley of the Nen, some eight miles eastwards of the busy town of Northampton, is Castle Ashby, for several centuries the principal country residence of the Comptons, and long known for the stately architecture of the historic mansion, the charms of the richly-timbered park, the diversified woodlands, and the beauty and high-keeping of the extensive gardens. The fame enjoyed by the Northamptonshire home of this great family is no new creation. Nearly a century and a half ago Jago, whose name, like that of many other of the minor poets, has passed into oblivion, advised in one of his descriptive poems his readers to—

> "Come, haste with me while now 'tis early morn,
>
> * * *
>
> To where yon point
> Projecting hides Northampton's ancient seat,
> Retired, and hid amidst surrounding shades;
> Counting a length of memorable years
> And solid worth."

The advice given by Jago is as applicable at the present time as when he was looking after his little flock at Harbury, and dividing his leisure between gardening and writing blank verse, and, as evidence that the views expressed upon this point are in no way singular, it will suffice to point to the large number of visitors from the neighbouring towns on the days when the gardens are, by the generosity of the noble owner, open to the public. The charms of Nature and art are, indeed, so happily combined at Castle Ashby as to afford unbounded pleasure to the visitor, while there is so much of interest in the history of the domain as to immensely enhance the enjoyment a leisurely walk through the spacious gardens and grounds is so well able to afford.

It is a delightful drive from Northampton to Castle Ashby; but the mansion is the most readily reached from Castle Ashby station on the Peterborough branch of the London and North-Western Railway, from which it is about two and a half miles, the road for the greater distance being through the park. From the Yardley Hastings side of the park the house is approached by a magnificent avenue commencing at Yardley Chase, three miles distant. The lodge at this entrance is of handsome elevation, and in addition to the Arms of the family, has on the outer pediment the inscription, "Dominvs cvstodiat introitvm tvvm" (The Lord preserve thy coming in), and on the inner pediment, "Dominvs cvstodiat exitvm tvvm" (The Lord preserve thy going out). The avenue is formed with four rows of trees consisting of oak, elm, and beech, and the two inner rows are about three hundred feet apart, and with this space and a broad drive, it is free from the defect which characterises so many of the avenues leading to old country houses in the United Kingdom. Early in the eighteenth century, avenues were planted on the four sides of the mansion, but with the exception of the one which terminates at Yardley Chase, they have disappeared, and it is probable they were broken up, if not wholly removed, when, towards the end of last century, the park and grounds were remodelled by Launcelot, or, as he was popularly designated, "Capability" Brown, then at the zenith of his popularity as an exponent of the English school of Landscape Gardening. From the Castle Ashby station the park is entered by an elegant Gothic lodge, bearing the Arms of the third Marquis, and by taking the footpath that branches off from the drive soon after passing the entrance gates, an eminence is reached from which a magnificent prospect, extending over many miles, is obtained of the fertile valley of the Nen. To again quote from Jago—

> "We view the subject vale sublime,
> And unimpeded. Hence its limits trace,
> Stretching in wanton boundary, from the foot
> Of this green hill as far as human ken

Can reach, a theatre immense! Adorned
With ornaments of sweet variety,
By Nature's pencil drawn—the level meads,
A verdant floor, with brightest gem inlaid,
And richly painted flowers—the tillage plain
Wide waving to the sun a rival blaze
Of gold, best source of wealth!

The "tillage plain" may have had its area materially reduced by the changes that have been made in agricultural practice during the second half of the present century, but the scene, if less varied in colouring during the autumn, is throughout the year of marvellous beauty.

From this point away to the south-east may be seen under favourable atmospheric conditions the spire of the church of Gaston Maundit rising from the midst of the masses of trees, and this village is of interest from the fact that Bishop Percy, the editor of the "Reliques of Ancient Poetry," was vicar of the parish for nearly thirty years. During this period Percy prepared his famous work, of which the MS. is preserved in the British Museum, and entertained Garrick, Goldsmith, Johnson, Shenstone, and other kindred spirits. Many other objects of archæological or historic interest come within the range of vision as the eye roams over the fair prospect, delighted with its manifold charms; but as they do not fall within the scope of the object I have now in view, this indication of their existence will suffice. Proceeding onwards through the park in the direction of the mansion, a glimpse of the venerable pile is obtained through the trees, the grey masonry presenting a pleasing appearance in contrast to the dark green masses of foliage by which it is surrounded. As the mansion is approached through the elegant wrought-iron gates of Italian workmanship, with their handsome pillars from designs by Wyatt at practically the end of the avenue, it can be seen, to quote from Cautley, that—

"No hanging bartizan proclaims defiance,
No thunder-throated cannon hath a place
On flanking turret, or the curtain's space
Arcaded with Italia's elegance.
But, where grim battlements are wont to frown,
The pious architect, with sculpture rare,
A psalm hath letter'd in the massive stone;
The graven scripture peoples the blest air
With holiest thoughts; these the eye calleth down
To teach the heart sincerity through prayer."

VIEW ON UPPER TERRACE.

WEEPING BEECH.

The origin of the name of the estate is not difficult to trace. In the Domesday Book it is entered as Asebi, presumably the place of the ash tree; but later it became known as Esseby David, taking its title from a lord of the manor, one David de Esseby, to whom it belonged in the reign of Henry III., and whose effigy in chain armour has a place in the Lady Chapel of the church of Castle Ashby. At the end of the fourteenth century Ashby, with the advowson of the church, became the property of Walter de Langton, and a few years later the bishop obtained a license from Edward I. to "fortify the mansion at Esseby with kernelled walls after the manner of a castle." This alteration in the structural details of the then existing mansion brought about a change in the name from Esseby David to Castle Ashby. This was accomplished in a very gradual manner, and it is interesting to observe that while in the reign of Edward III. it was designated Castle Ashby by Sir William de la Pole, to whom it then belonged, it was as late as the reign of Elizabeth described under its old name. Sometime during the fifteenth century the estate passed into the hands of the De Ruthyn family, and as they had a seat at Yardley Hastings the mansion at Castle Ashby was abandoned and allowed to fall into decay. In less than a century it had become a ruin, and with reference to its condition Leland wrote "Almost in the middle way betwixt Welingborowe and Northampton I passed Assheby, more than a mile of on the left hand, wher hath been a castle that is clene downe and is made but a septum for bestes." With the purchase of the property by the Comptons a change for the better was effected and the foundation of the present greatness of the estate laid.

It would appear that Sir William Compton, who accomplished so much in raising the family to a greater degree of honour, purchased Castle Ashby in 1512, and leased the property, including the old ruined castle and an enclosure known as the "Castell Yarde." The lease expired in 1583, and soon afterwards the building of the present mansion was commenced; and although there may be some difficulty in fixing from readily accessible records the exact date, there can be no doubt that a very short period was allowed to elapse after the lease had fallen in, for a considerable part of the pile of buildings had been completed prior to the death of Henry, the first Lord Compton, in 1589. Camden observes, in his "Britannia," with reference to this matter: "From hence [Northampton] Nen maketh haste away by Castle Ashby, where Henry, Lord Compton, began to build a faire sightly house." The completion of the mansion as originally designed was accomplished by William, the second Lord Compton, who, in the reign of James I., was created Earl of Northampton. This nobleman had the good fortune to bring by marriage as much wealth into the house, as he had by his personal qualities added honour to it. He married Elizabeth, the daughter and heiress of Sir John Spencer, a wealthy Alderman of the City of London, and sometime Lord Mayor, and she was regarded as the richest heiress of her time. Sir John's wealth was estimated at a sum closely approaching a million sterling, and according to tradition a scheme was projected by the pirates of Dunkirk to carry him off in order to exact a ransom. There is also a tradition to the effect that when Lord Compton became fully acquainted with the immense sum that had been left by his father-in-law that he became unsettled in his intellect. I am not disposed to attach any importance to the tradition, for his lordship was by no means a weakly-minded man; but however that might be, there can be no doubt whatever that Lady Compton had a sufficient strength of mind to properly appreciate the magnificence of her dowry, and the necessity for the careful administration of the wealth she had brought into the house. We have evidence of this in the Harleian MSS., for amongst them we find a letter she addressed to her husband, in which she suggests the best mode of dealing with the funds and also sums that should be placed at her disposal for her personal use. The letter is highly interesting as illustrating some of the aspects of social life three hundred years ago; and with reference to the funds for her personal use, Lady Compton writes: "Now, I have declared to you my mind for the settling of your estate., I suppose it were best for me to bethink and consider within myself what allowance were meted for me. . . . I pray and beseech you to grant to me, your most kind and loving wife, the sum of quarterly to be paid. I would besides that allowance have £600 quarterly to be paid for the performance of charitable work." Then, after stating her requirements with regard to her "women" servants, horses, carriages, apparel, Lady Compton observes: "Also I would have to put in my purse £2,000 and £200," and "also I would have £6,000 to buy me jewels, and £4,000 to buy me a pearl chain." In this letter the desire is also expressed that Lord Compton should "build up Ashby House and purchase lands," and that this desire was granted we have the best possible proof in the magnificent mansion which affords such an excellent example of the architecture of the period.

Since the time when the first Earl of Northampton and this great heiress completed this magnificent pile, eight generations of this great family have passed away, all of whom have been more or less distinguished. Spencer Compton, the second Earl, was commonly called the loyal Earl of Northampton, for his attachment to Charles I., in whose cause he fell in the battle of Hopton Heath. The third Earl specially distinguished himself in Parliament, and was Speaker of the House of Commons in the parliaments of 1715 and 1722, and in 1727 was created Baron Wilmington. Thomson dedicated his "Seasons" to this nobleman, and in his dedication says,—

> "To the patron of her first essay
> The muse, O Wilmington! renews her vow,
>
> * * * * *
>
> Nor art thou skill'd in awful schemes alone
> And how to make a mighty people thrive!
> But equal goodness, sound integrity,
> A firm unbroken uncorrupted soul
> Amid a sliding age, and burning strong,
> To swell the brooding terrors of the storm;
> Not vainly blazing for thy country's weal,
> A steady spirit regularly free."

THE LAKE AND WATER LILIES.

ITALIAN ARCHWAY AND CLIPPED EDGES.

THE PRIORS WALK.

The question of "How to make a mighty people thrive," would also appear to have been uppermost in the minds of the successors of this distinguished member of the family, for, as the records show, each in his day warmly supported all movements that have had for their object the welfare of the people. Not the least zealous in the advancement of the material and moral welfare of the community is the present Marquis, who, as Earl Compton, took an active part in the government of the metropolis. Truly might it be said,—

> "Nor hath the sun with less propitious ray
> Shone on the masters of the various scene,
> Witness the splendid train! illustrious names,
> That claim precedence on the lists of fame."

The main building was presumably completed when James I. and his queen paid a visit to the Earl and Countess of Northampton in 1605. Originally the mansion consisted of a centre and two projecting wings, but later on a façade containing a chapel and long gallery, and connecting the two wings at their southern end was added from designs by Inigo Jones. The main entrance to the mansion is, it may be mentioned, on the southern side, and from this point an excellent view is obtained of the avenue, which is separated from the mansion by a spacious tennis lawn and a still more extensive cricket ground, the road at the termination of the lines of trees branching off to the right and left, and these branches describe a semicircle in approaching the house. The stately pile has a picturesque appearance from every point of view; and the lettered balustrades to which allusion is made in the lines by the Rev. S. T. Cautley, add much to the interest of a close inspection. On the outer and inner sides of the quadrangle, there are inscriptions precisely the same as those on the pediments of the lodge at the Yardley Hastings entrance to the park, and along the balustrade of the building surrounding the quadrangle are other scriptural texts. Commencing at the south end of the west wing is the inscription, in bold letters, "Nisi Dominvs cvstos cvstodixerit Dominvm frvsta vigilat qvi cvstodit eam" (Except the Lord, the Keeper, keep the house, in vain he watches who keeps it). Then follows, "Nisi Dominvs ædificavent omvm in vanvm laboraverant qui ædificant eam, 1624" (Except the Lord build the house, they have laboured in vain who build it). Along the outer balustrade we read, "Beati omnes qui timent Dominvm qui ambvlant in viis ejvs. Lavdate nomen, Domini. Amen. 1627" (Blessed are they who fear the Lord, who walk in his ways. Praise ye the name of the Lord. Amen.) The same idea has been carried out in the design of the balustrades of the terraces, which are of a much later date, but the lettering is in English. The inscription on the balustrade of the upper terrace is, commencing at the west end, as follows: "The grass withereth, the flower fadeth, but the word of God abideth for ever." Along the balustrade of the lower terrace we read, "Consider the lilies of the field, how they grow, they toil not, neither do they spin, yet I say unto you Solomon in all his glory was not arrayed like unto one of these." Beyond is a similarly wrought inscription in Latin in memory of the late marchioness.

The architecture of the mansion is so well shown in the large illustration as to render further description unnecessary, and it will suffice to say that the building is an excellent example of the Tudor style, and that the apartments are in keeping with so magnificent an edifice. These latter are richly stored with works of art and objects of vertu. Nearly all the leading schools of painting are represented by works of the principal masters, the family portraits being particularly noteworthy. The tapestry in the several apartments is of special interest, and mention may well be made of the finely carved oak chimney-piece in King William's dining-room, a magnificent saloon on the first floor at the north-west corner of the building, and named in honour of William III., who was entertained here. The chimney-piece is nearly three centuries old, having been brought from Sir John Spencer's mansion at Canonbury, and is properly considered one of the finest examples of wood carving of which there is record. The view obtained from the battlements extends over a wide range of country, and is so exceedingly beautiful that those who have an opportunity of making the ascent will find in the prospect an ample return for the labour involved. As seen from this commanding position, to again quote from Jago,—

> " The late-trod plain looks like an inland sea,
> View'd from some promontory's hoary head,
> With distant shores environ'd ; not with face
> Glassy and uniform, but when its waves
> Are gently ruffled by the southern gale,
> And the tall masts like waving forests rise."

Such is the scene that from the battlements

> " Displays its graces, intermixture sweet
> Of lawns and groves, of open and retired.
> Vales, farms, towns, villas, castles, distant spires,
> And hills on hills, with ambient clouds enrobed,
> In long succession court the labouring sight,
> Lost in bright confusion."

The walls of the mansion are for the most part clothed with vigorous growing plants of scandent habit, chief among them being an immense specimen of the Virginian Creeper, which, in taking on its autumnal charms, produces a charming effect in contrast with the grey lichen-stained masonry. The Austrian briars flourish with the protection the walls afford, and running riot, annually produce in prodigal profusion their attractively coloured flowers. On the eastern side are several fine specimens of Harrisoni, which appears to be quite at home at Castle Ashby, for there are several finely developed specimens trained to the masonry of the large conservatory. Clematis flammula also grows here with great vigour, and its drapery of green, bespangled in due season with silvery star-like flowers, is pleasing at all times.

Highly-dressed grounds surround the mansion on all sides ; on the west and northern sides are the magnificent terrace gardens, while on the east it is flanked by shrubberies and plantations, amid which nestles the interesting church ; and on the south, as already indicated, is a fine expanse of closely-shaven lawn devoted to tennis and other games associated with the garden. The terrace gardens as they now exist are creations of the second half of the present century, and were formed about forty years ago from designs by Mr. Thomas, and are excellent examples of his highly successful work. They are not the first of the terrace gardens at Castle Ashby, for there is still an old plan in existence of a large terrace garden on one side of the mansion. When the garden disappeared cannot now be stated with exactitude, but it is reasonable to assume that it was swept away by Brown when engaged in making alterations and improvements, for he had but little sympathy with formality in the garden, On the northern side of the mansion, and running its whole length, is a broad gravel walk, and from this there is a gradual slope of velvety turf to the first terrace, on which is arranged a geometrical flower garden in the old French style, remarkably elegant in design, and of special interest as a proof of the great taste of the third Marquis of Northampton, who had the terraces formed, and evinced a close personal interest in the work while it was being carried out by Mr. Thomas. This garden is embellished by two fountains and some closely clipped trees and shrubs, and the beds, which are set in a green carpet of turf, are constantly furnished with plants, as both spring and summer displays of flowers are regarded as essential to the full enjoyment of the garden. At the north-west corner of this terrace is the wishing well, and this has much that is of interest associated with it, for it was in existence when the original house, which Leland described as "now clene down," was occupied. The well is now enclosed by a handsome wall, surrounded by seats, and ornamented by a canopy of the grape vine.

The lower terrace garden on the north side of the mansion has undergone considerable alterations within a comparatively recent period. It has now a carpet of turf, intersected by gravel walks, and on this have been designed beds representing the rose, shamrock, and thistle, and surmounted by a crown, and monograms have also been cut in the grass, each one consisting of the initial letters of the names of the four late marchionesses. The roses and thistles and the crowns may be assumed to indicate the favours of Henry VIII. and James I., which, as so strikingly exemplified in the history of the house, were fittingly bestowed. Beyond the lower terrace is the laurel garden, so called presumably from the large scrolls of the common laurel and the fine specimens of the Portugal laurel, the standards of the last-named being especially remarkable for the splendid development of their heads. There is also a row of exceptionally fine standards of the Portugal laurel alongside the raised walk at the end of the garden, which connects the upper and lower terraces, and forms, as it were, a divisional line between the formally arranged beds and the more naturally-arranged trees and shrubs that separate the terrace from other parts of the grounds to the north-east, and form an effectual shelter from the cold winds from that quarter.

From this point a walk proceeds through the ornamental plantations for a distance of about two and a half miles, and alongside this we find many choice trees and shrubs and a prodigality of bulbous and other flowers that have been naturalised with much success. There are also some fine specimens of the Cedar of Lebanon. One of the cedars in the grounds is said to be nearly one and a half centuries old, but it has suffered from the ravages of time, and is now of interest chiefly for its age. At the north-east corner of the terrace and within a stone's throw of the mansion is the church of Castle Ashby, and, half hidden amid the trees, the edifice presents a picturesque appearance and is of much interest. The church contains several monuments to the memory of members of the family by Tenerani, Marochetti, Blore, and other sculptors. There is also an effigy in chain mail supposed to be that of David de Esseby, the lord of the manor about the middle of the thirteenth century, and a large brass of William de Ermine, a rector, who was instituted in 1367 and died in 1401. In the churchyard is an exceedingly beautiful monument to the late Marchioness of Northampton, who died in 1877. Among the tombs of the members of the family and their retainers are those of the three head gardeners immediately preceding Mr. Hayes, all of whom died in the service of their noble employers. These are Mr. W. Hardy, who died in 1867; Mr. George Beech, in 1883; and Mr. Henry Birch, in 1894—all of whom rendered valuable services in the cause of horticulture in their day. In walking through this small but interesting God's acre one might well be excused for moralising, and saying, with a long-forgotten poet,—

> " Nor youth, nor beauty, nor employment high
> Could grant protection from the rude assault
> Of that barbarian, Death ; who, without form,
> To courts and cottages unbidden comes,
> And his unwelcome embassy fulfils,
> Without distinction, to the lofty peer,
> The graceful bride, or peasant's homely race."

Immediately beyond the southern boundary of the churchyard is the first of a series of ornamental gardens that extend hence to the fruit and kitchen gardens. Passing through a wicket the visitor crosses a great breadth of turf, on which are arranged numerous trees and shrubs, remarkable for elegance of aspect or the beauty of their flowers. Especially deserving of mention are fine specimens of the tulip tree and catalpa, and handsome groups of weigelas, tree pæonies, arbutus, shrubby spiræas, azaleas, and rhododendrons. On the western side is a broad belt of trees, in which are some huge beeches, and—

> " Whose lofty elms and venerable oaks
> Invite the rook, who high amidst the boughs
> In early spring his airy city builds,
> And ceaseless caws amusive."

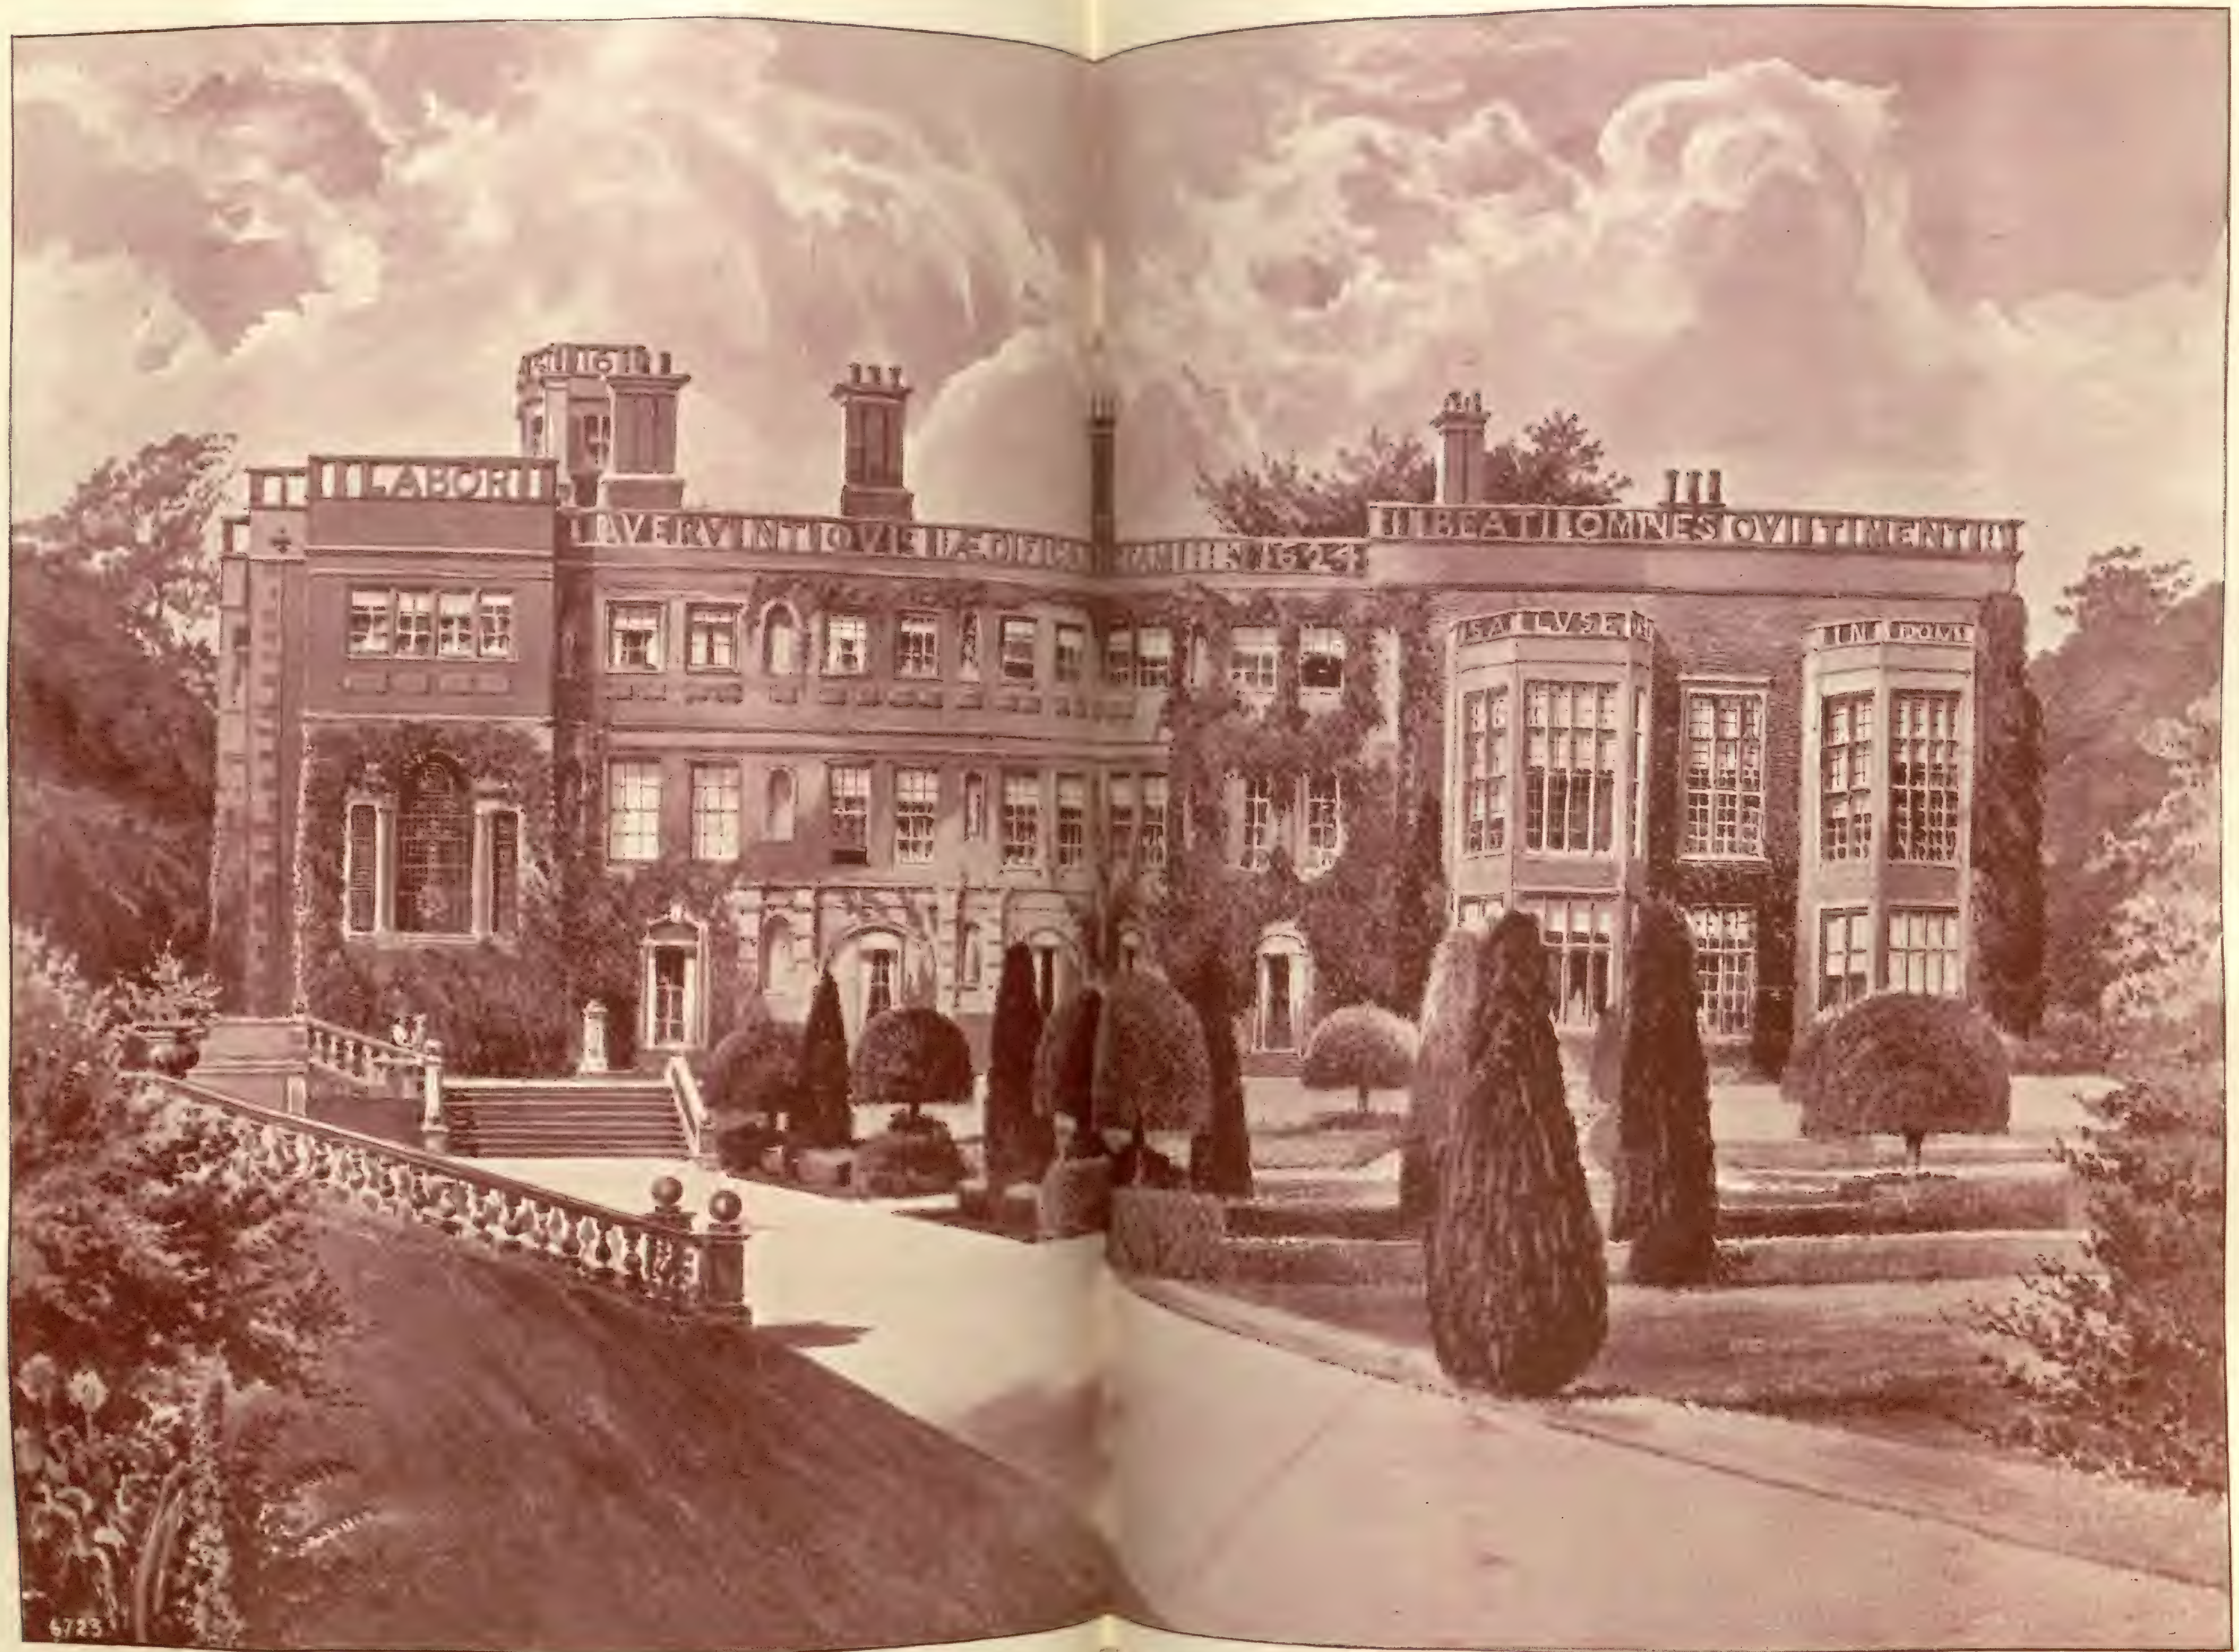
Immediately beyond, still proceeding southwards, is the Italian garden with a conservatory of noble proportions at the north end, and an architectural screen, with corridor and balcony at the southern end. The corridor affords shelter from rough weather, or the heat of a summer day, while from the balcony, which extends nearly the whole width of the garden, a good view is obtained over a considerable area of the pleasure grounds, and nearly the whole of the kitchen and fruit gardens. The photograph from which our illustration of the Italian garden has been reproduced was taken from the platform immediately over the gateway, which is flanked by handsome pillars, and on the southern side of the wall are spacious glass houses. As will be seen from a glance at the illustration, the Italian garden is divided into four equal portions by the four walks that radiate from the centre, and in each of the four segments there is a sunken panel with beds outlined in box and filled with coloured earths. These panels, if not in accordance with the views that obtain on the question of garden ornamentation at the present time, are of interest as an example of garden decoration which was not unknown in Bacon's day, and enjoyed a considerable degree of popularity nearly half a century ago. The central walk has on either side vases and English yews alternately, and on the cross walk there are Irish yews with vases, and near the centre are specimen cupressus. Also of interest in this garden is a large mulberry tree which, from its venerable appearance, must have occupied its present position close upon two centuries.

Passing through the arch at the southern end of the Italian garden several distinct features attract attention. The main walk is flanked on either side by a closely clipped box hedge eight or nine feet high and five or six feet through, and to the right and left are enclosed gardens devoted to flowering plants. To the right is a rose garden consisting of long beds radiating from a small rockery on the north side, and clothed with attractive alpines. The beds have standard roses along the centre, and are filled during the summer with flowering plants that attain perfection in that season, and during the winter and spring with bulbous and other spring-flowering plants, hyacinths, tulips, and narcissi being extensively planted. To the left of the main walk there is a spacious breadth of turf on which are large beds wholly devoted to carnations, and containing in the aggregate many thousands of plants. These are grown chiefly for the supply of cut flowers, which at Castle Ashby, as in the case of other large establishments, are in much request. Beyond the rose garden, on the right, is a large garden chiefly devoted to annual flowers suitable for cutting for indoor decorations ; and contiguous to this is a second rose garden, with a rustic house in the centre, and with trellises over which Crimson Rambler and Gloire de Dijon spread their luxuriant growth, and produce a wealth of flowers. The sides of the rustic house are clothed with Gloire de Dijon rose, clematis, Aristolochia sipho, Jasminum nudiflorum, and other hardy climbers. The beds are chiefly filled with dwarf roses, the principal varieties being Baroness Rothschild, La France, Senateur Vaisse, Duke of Edinburgh, Old Moss, Mrs. J. Laing, and Charles Lefebvre. On two sides of this garden are pleached alleys, which constituted so important a feature of the Elizabethan period, and therefore singularly appropriate in the grounds of a mansion which was built upwards of two hundred years since. To the left of the main walk, and facing the carnation garden, is a spacious border devoted wholly to the German and other flag iris, and the collection of varieties is so comprehensive and the plants so vigorous that it is well able to afford an immense amount of pleasure throughout the season of flowering.

Hardy plants other than those already mentioned are cultivated extensively and with much skill, and these, in their respective seasons, constitute a delightful feature of the gardens, and furnish a wealth of material for house decoration. The Prior's Walk, by which the [illegible] is reached, has on either side broad borders filled with pæonies, [illegible], [illegible], asters, herbaceous phloxes, Oriental and other poppies, iris, Spiræa aruncus, doronicums, centaureas, Chrysanthemum maximum, pyrethrums, delphiniums, trollius, megaseas, and a host of other good things. It may indeed be said with truth that these borders contain—

> " Plants diverse and strong,
> That ev'ry day their blossoms change
> Ten thousand lovely hues !
> With budding, fading, faded flowers
> They stand, the wonder of the bowers,
> From morn to evening dews."

Supplement to the Gardeners' Magazine, June 4th, 1898.



CASTLE ASHBY, THE SEAT OF THE MARQUESS OF NORTHAMPTON.

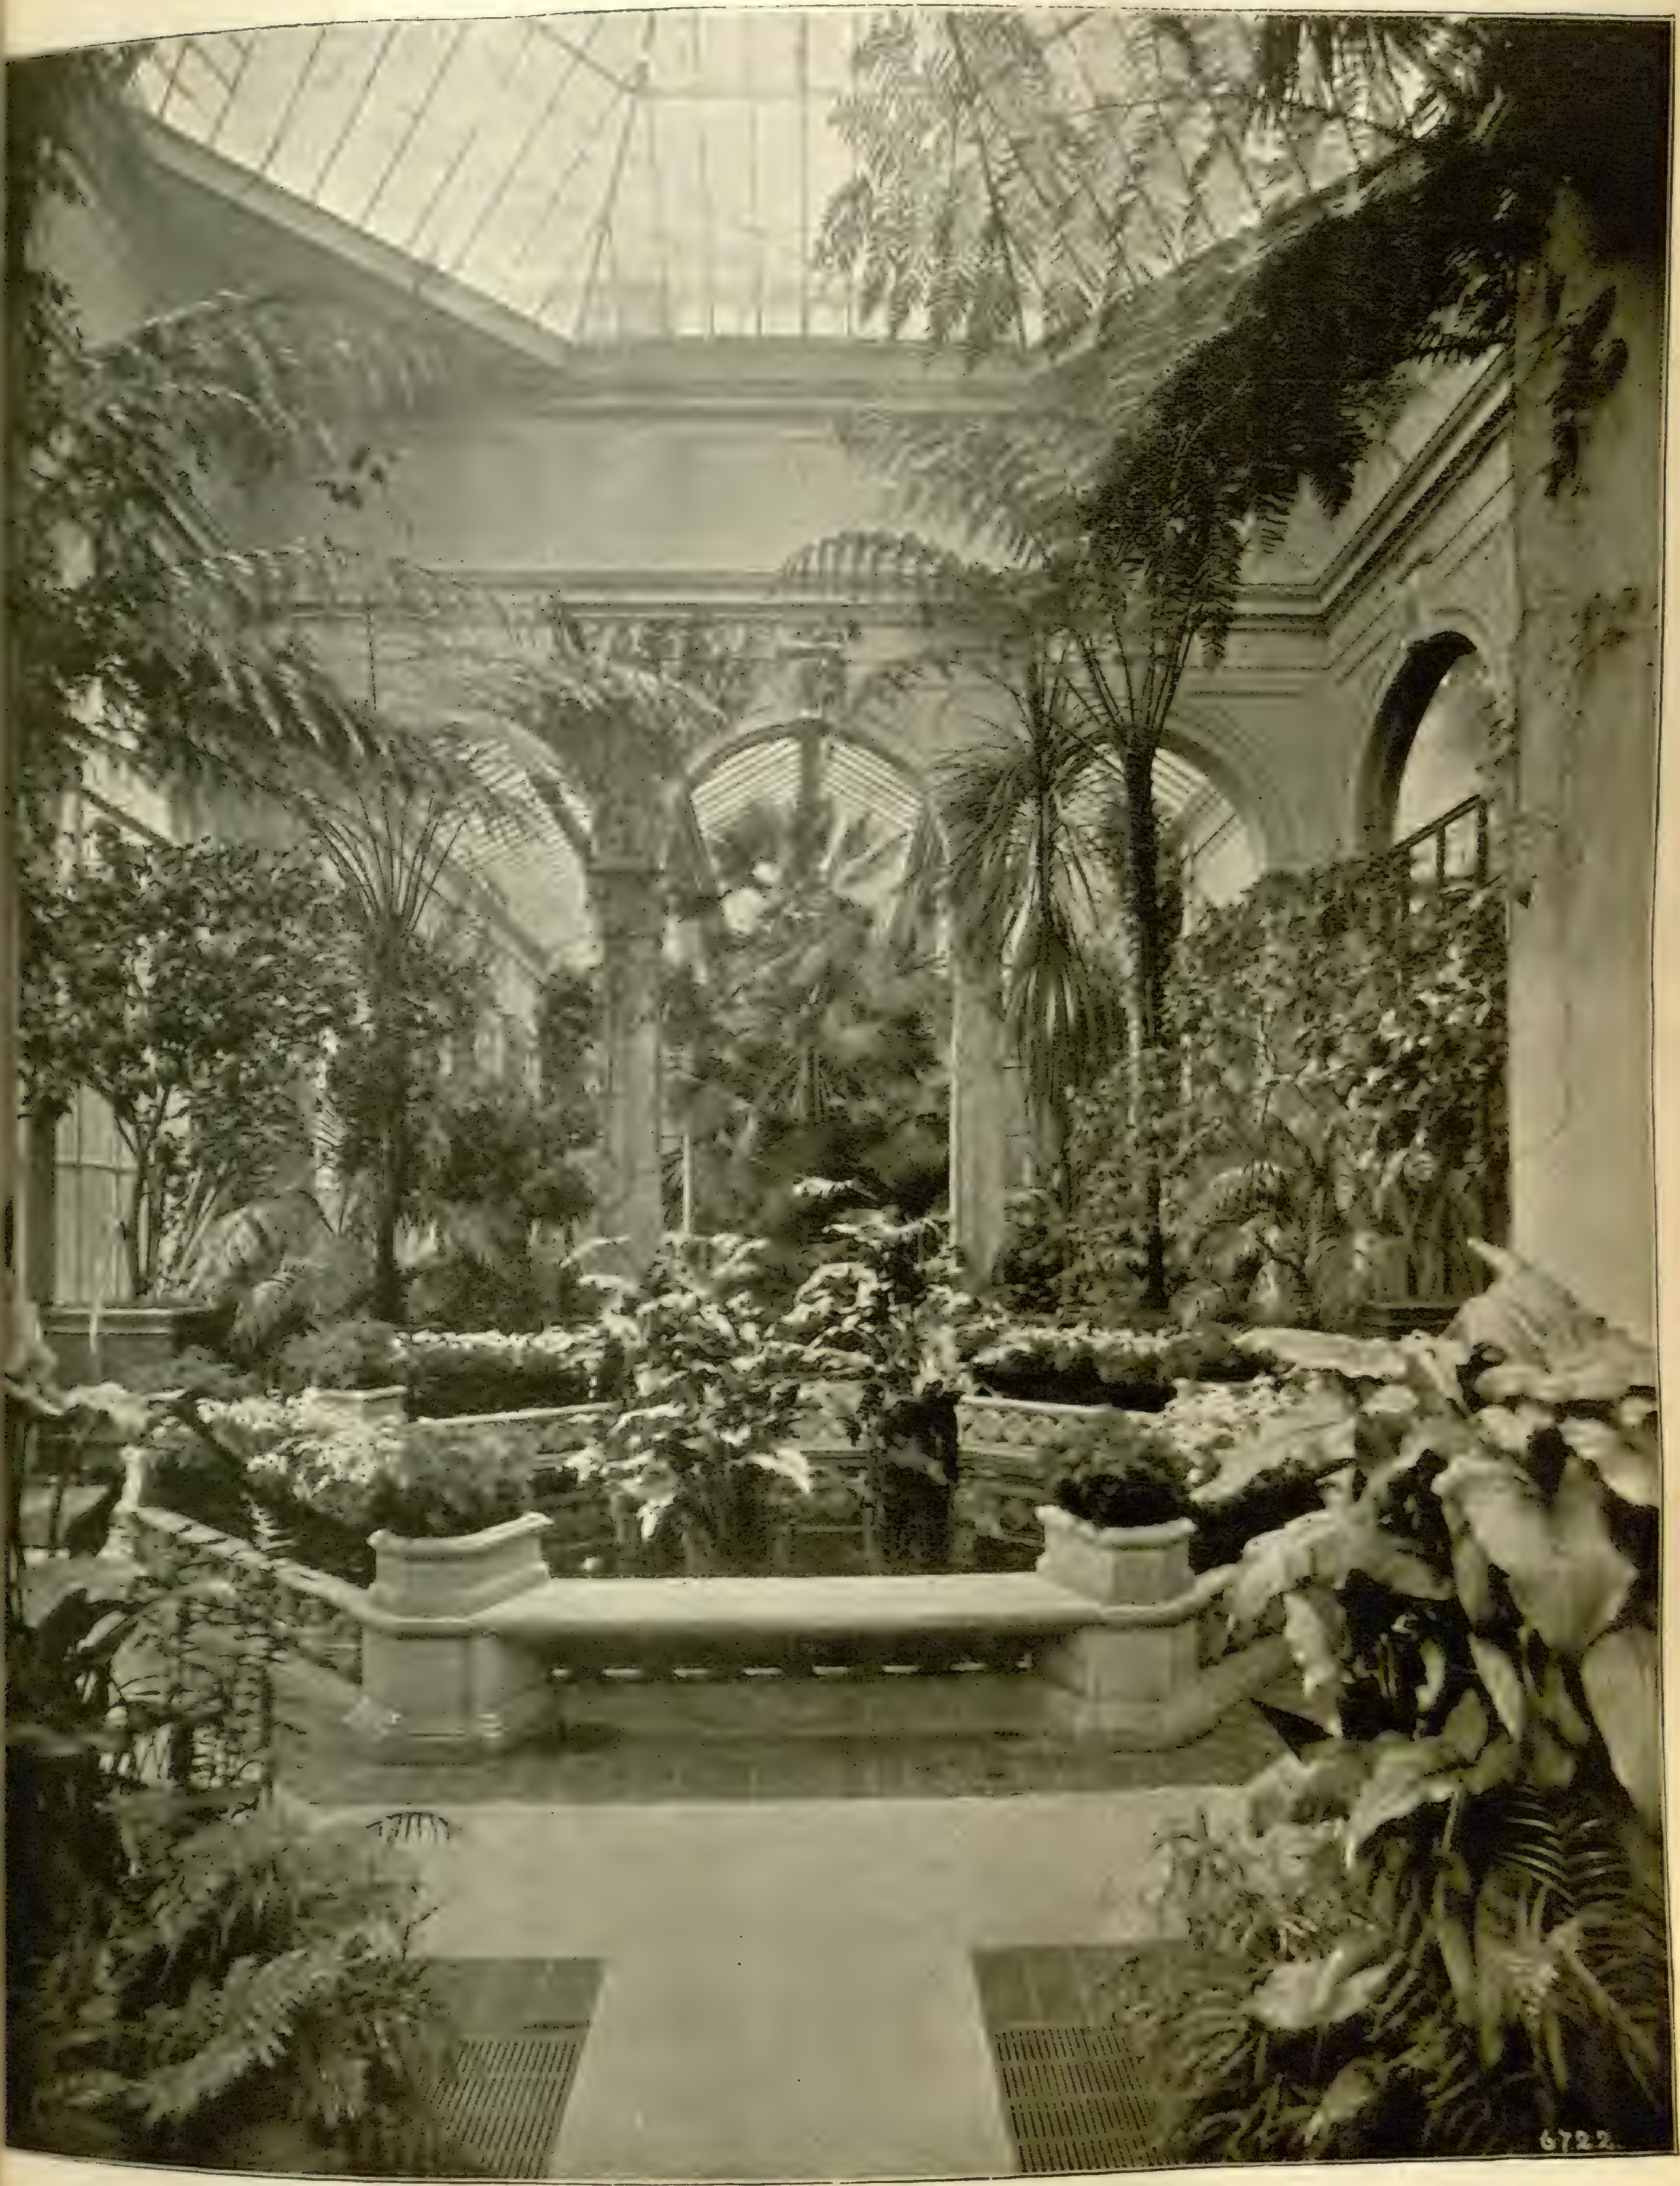
SUPPLEMENT TO THE GARDENERS' MAGAZINE, JUNE 4, 1898.



[From a photograph by Bedford, Lemaire, and Co.

INTERIOR OF GREAT CONSERVATORY.

The herbaceous borders at Castle Ashby bear the impress of skilful management, and it is interesting to observe that while there is no over-crowding of the plants, or of the growth of each individual, each specimen is of sufficient proportions to present an effective appearance. In this respect they differ materially from some borders that annually come under my notice, and they may be described as excellent examples of the results that may be obtained from following the advice so frequently given in these pages.

The arboretum is situate on the eastern side of the Italian garden, and contains many noble specimens, chiefly of conifers. Prominent among the deciduous trees is a magnificent example of the weeping beech, which at once attracts attention by reason of its great size and elegant contour, the long slender branches tumbling over each other like the spray of a fountain. Especially noteworthy also among the deciduous trees is the specimen of the double-flowered cherry, and in each recurring spring its—

> "Boughs above us spread
> The whitest shade was ever seen,
> And flicker, flicker, came and fled
> Sunspots between."

The effect produced by this cherry when garlanded by its myriads of snow-white blossoms is at all times good, but it is strikingly beautiful when the tree is, as in this instance, associated with the sombre-hued conifers. Remarkable for their height and development are the examples of Cedrus atlantica, Abies canadensis, A. Douglassi, Picea pinsapo, P. nobilis, Sequoia sempervirens, Wellingtonia gigantea, and Cryptomeria japonica, these being sixty feet or so in height. Conspicuous among the conifers of recent introduction are examples of the exquisitely beautiful Picea Parryana glauca, the silvery hue of these affording a pleasing contrast to the dull colouring of the majority of the firs and pines.

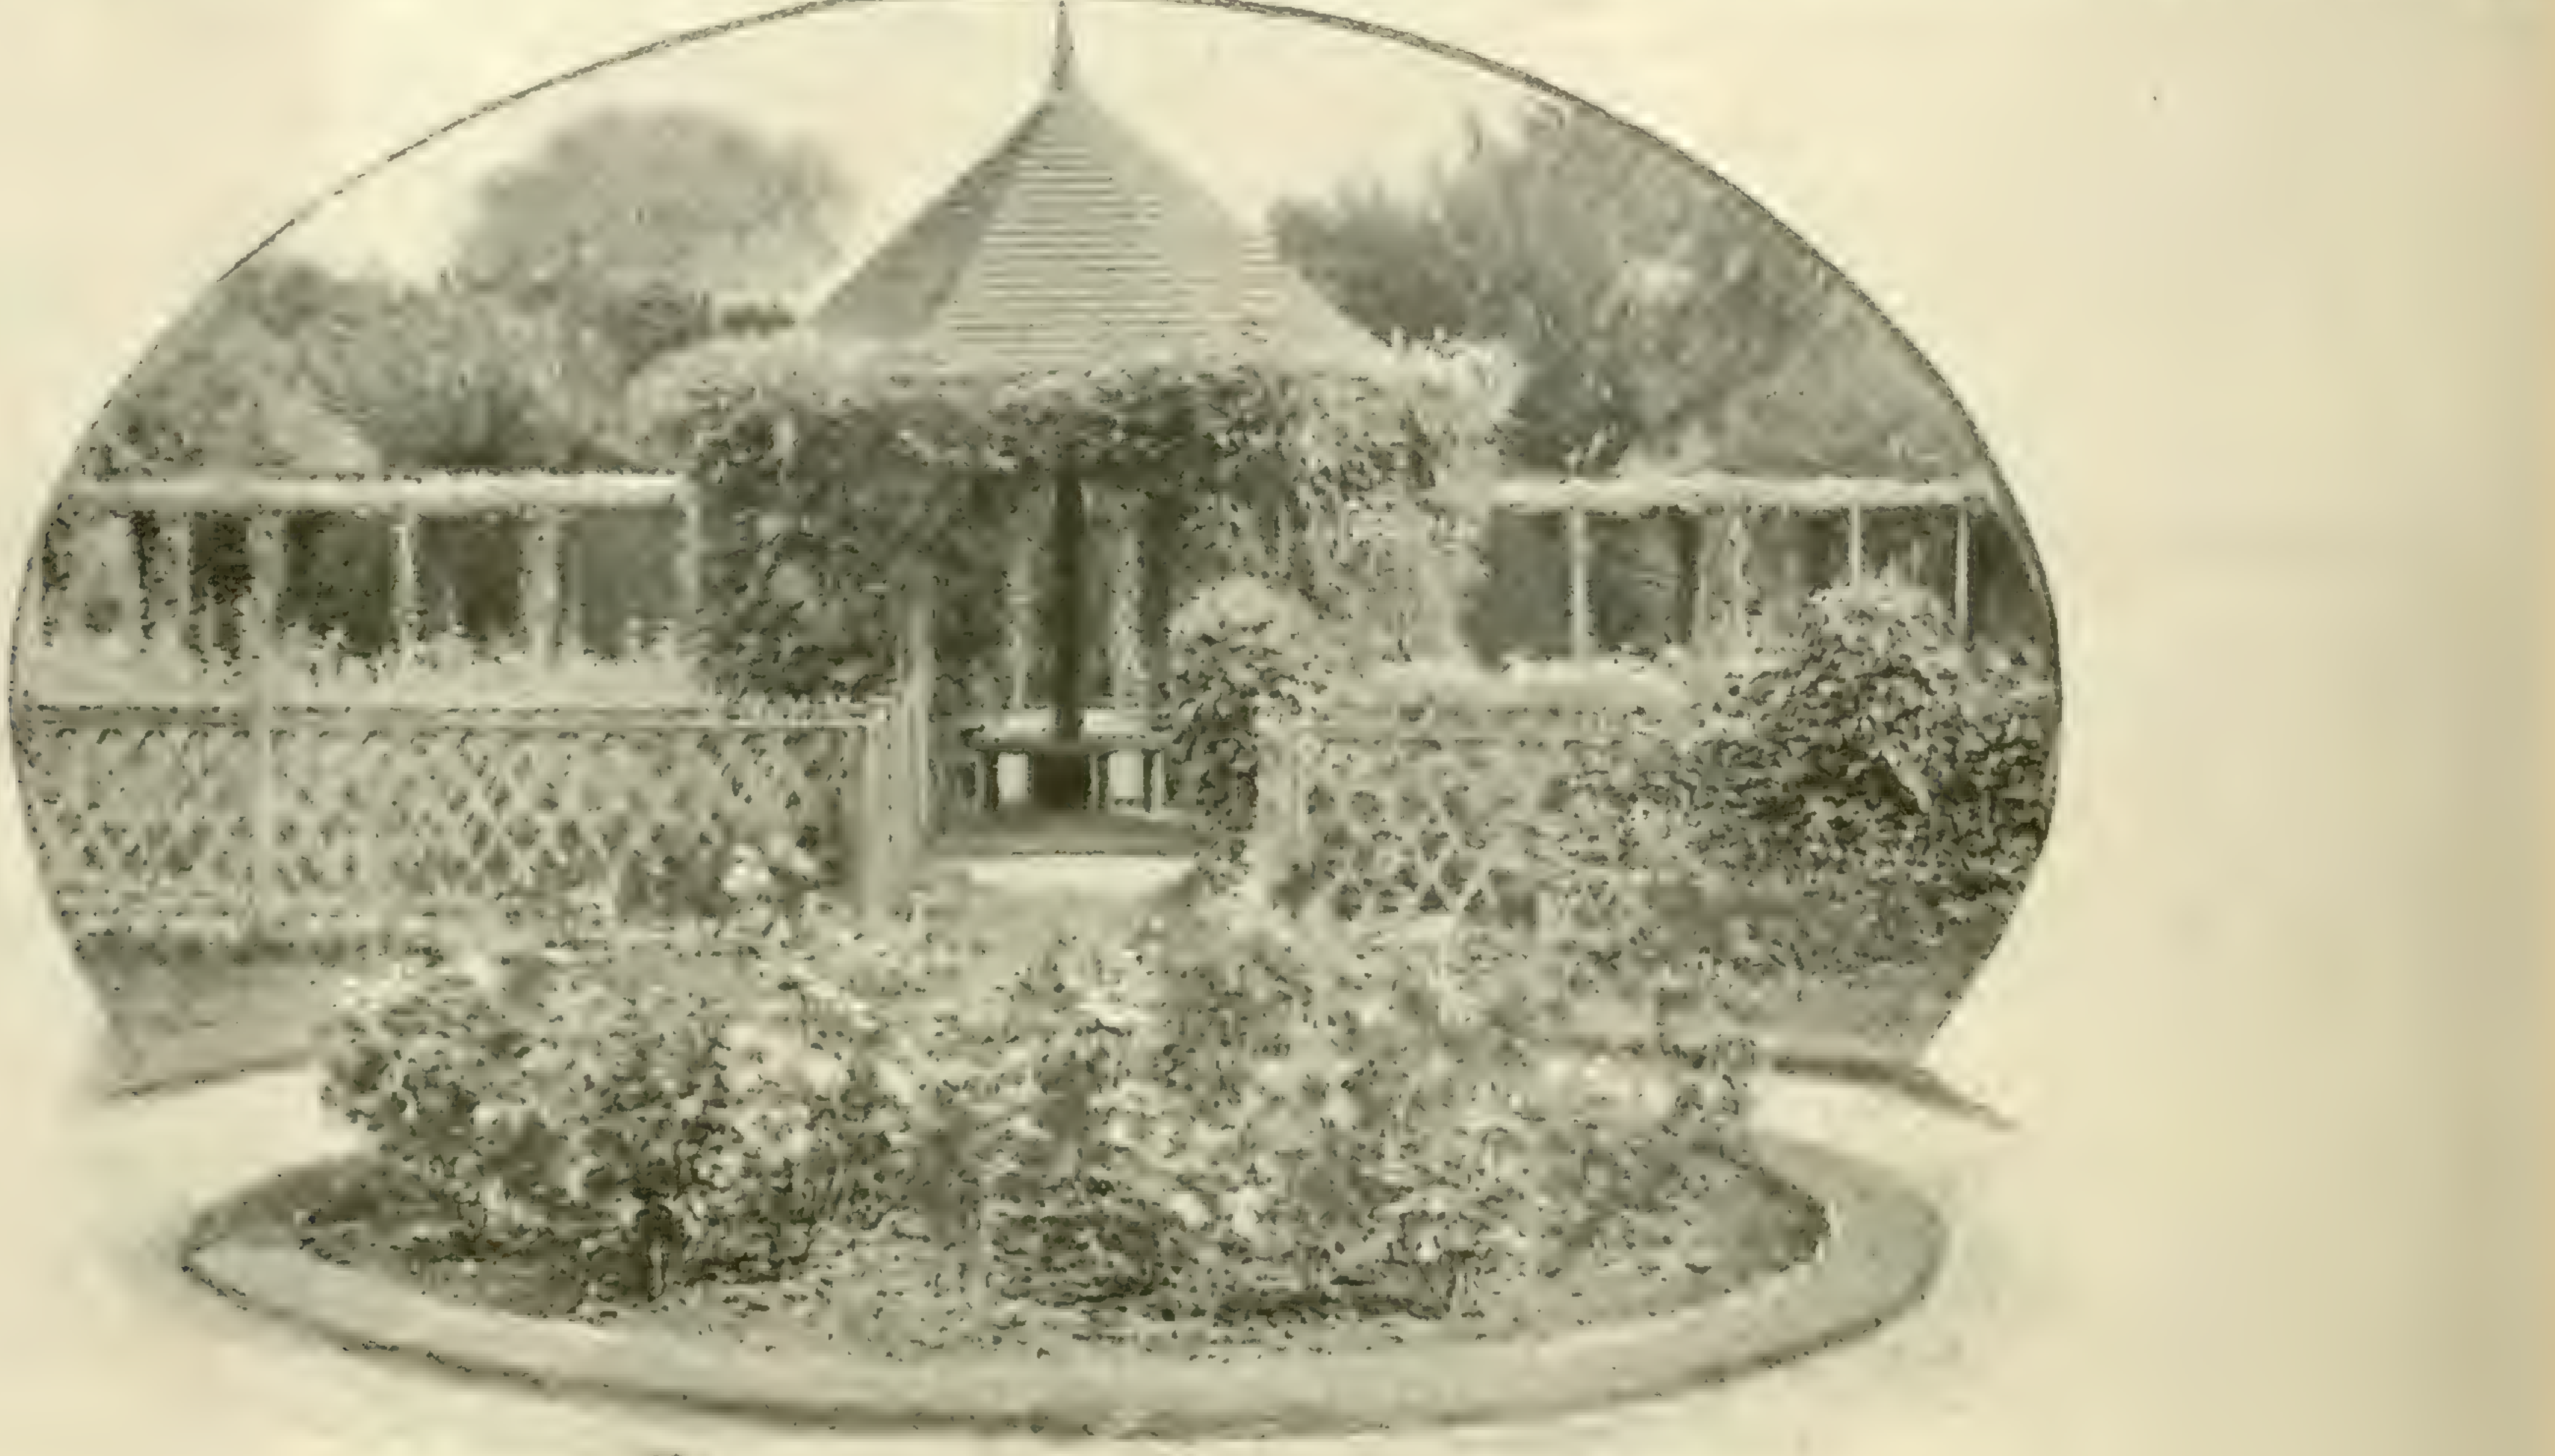
Crossing the stream there is a broad stretch of lawn sloping down to the water's edge for a considerable distance, and intersected by a walk, which is continued into the plantations, and connects with the walk leading to the terrace garden. On the lawn are numerous finely developed deciduous trees, and it may be truly said that—

> "Beneath their waving umbrage Flora spreads
> Her spotted couch, primrose and daffodil
> Profuse, with every simpler bud that blows
> On hill or dale."

Here the cultivation of flowers in the grass has been brought to a high degree of perfection by Mr. Hayes, and from the time the snowdrop makes its appearance until the poet's narciss has lost its charms, the turf is bespangled with flowers of varied hues; golden crocuses and daffodils, crimson polyanthuses, soft-tinted primroses, and some other subjects that are able to hold their own in a struggle for existence amongst the grass may each be numbered by the thousand, and the profusion of flowers, produce so beautiful a picture that the visitor during the spring season might well be excused if, when passing along the walk, he, with the poet, exclaimed,—

> "Hail happy lawns! Where'er we turn our eyes
> Fresh beauties bloom and opening wonders rise."

By following the stream for some distance, and making a detour through the ornamental plantation which commences near the church, the fine sheet of water that gives so much life to the landscape, and so materially enhances its charms when seen from the battlements of the mansion or the terrace, is reached. The lake has a large expanse, and is probably the work of Brown, for it possesses some of the peculiarities that characterise his style. Whether the lake is the work of Brown or not, it forms a charming feature, and it is a point of some importance to mention that in no part is the bank so crowded with trees as to cast a deep shadow on the water and give it the gloomy aspect characteristic of so many water scenes in the United Kingdom. Yet there is sufficient vegetation to give life and diversity to the margin, and to produce a variety of lights and shadows on the water. On turning from the broad features of the water scenery to the details of the lake, it is gratifying to find that the cultivation of water plants is here, as in some other great gardens, receiving increased attention. Hardy bamboos are being grouped in suitable positions on the banks of the lake, while its margin is fringed with the most beautiful of the semi-aquatics which form a large group of exceedingly interesting plants. On the glassy face of the lake float the finest of the water lilies, which have been greatly augmented in numbers and enhanced in beauty by the art of the hybridist. With the several hardy species well known to all who are interested in the water garden, are the finest of Marliac's hybrid Nymphæas, which grow with great luxuriance and bloom profusely; their large pleasingly coloured flowers in contrast with the snow-white chalices of the "stately river queen," attract so much attention from visitors during the summer months. It is satisfactory to place on record the fact that water gardening is being conducted on an adequate scale and with much success at Castle Ashby, for the gardens are visited annually by large numbers of all classes, and it is reasonable to assume that the object lessons given in this, as in other phases of gardening, cannot fail to prove of great value in extending a knowledge of the most beautiful kinds, the conditions under which they attain the highest degree of development, and the positions in which they appear to the greatest advantage.



ROSE GARDEN AND RUSTIC PAVILION.

Contiguous to the arboretum, and on the south side of the kitchen garden, is a broad expanse of grass, to which special attention has of late years been given with a view to its greater ornamentation. It was originally intended for an orchard, and a considerable proportion of the area was planted with bush trees, but the position is not considered the best possible for hardy fruits, and it is intended to form an orchard on a more suitable site and to plant the space with groups and specimens of ornamental trees and shrubs. Alongside the broad walk are rustic posts connected with chains, and over these may be seen—

> "Virgin's bower trailing airily,
> With others of the sisterhood."

The virgin's bower in this case comprises the finest of the large-flowered clematis, amongst which the popular C. Jackmanni is conspicuous, and the sisterhood includes several species of ampelopsis and lonicera, and the several subjects produce in combination a pleasing effect from early in spring until the autumn, when the ampelopsis take on their characteristic colouring. Along the southern side of the enclosure is a broad walk skirted by large beds filled with tea roses distinguished by their robust habit and freedom of flowering, and between the beds are specimens of the most beautiful of the Penzance briars, and these, having plenty of room for their development, spread out their strong shoots to the sun and air, and become in due season garlanded with flowers of exquisite beauty. The tea roses have evidently been placed under the conditions favourable to their wellbeing, and consequently they grow vigorously and bloom profusely, and add materially to the attractions of the grounds. Along the lower side of this lawn—

> "The copious stream
> With winding grace the stately current leads,
> The channel'd lawn its bounteous stream repays,
> With ever verdant banks and cooling shades
> And wandering paths that emulate its course."

Much might be written with reference to the varied and interesting plantations, woodlands, and other arboreal features of the park and pleasure grounds, but with regard to these, it must now suffice to [illegible] that they contain much that is of interest to those who take an interest in ornamental and timber trees.

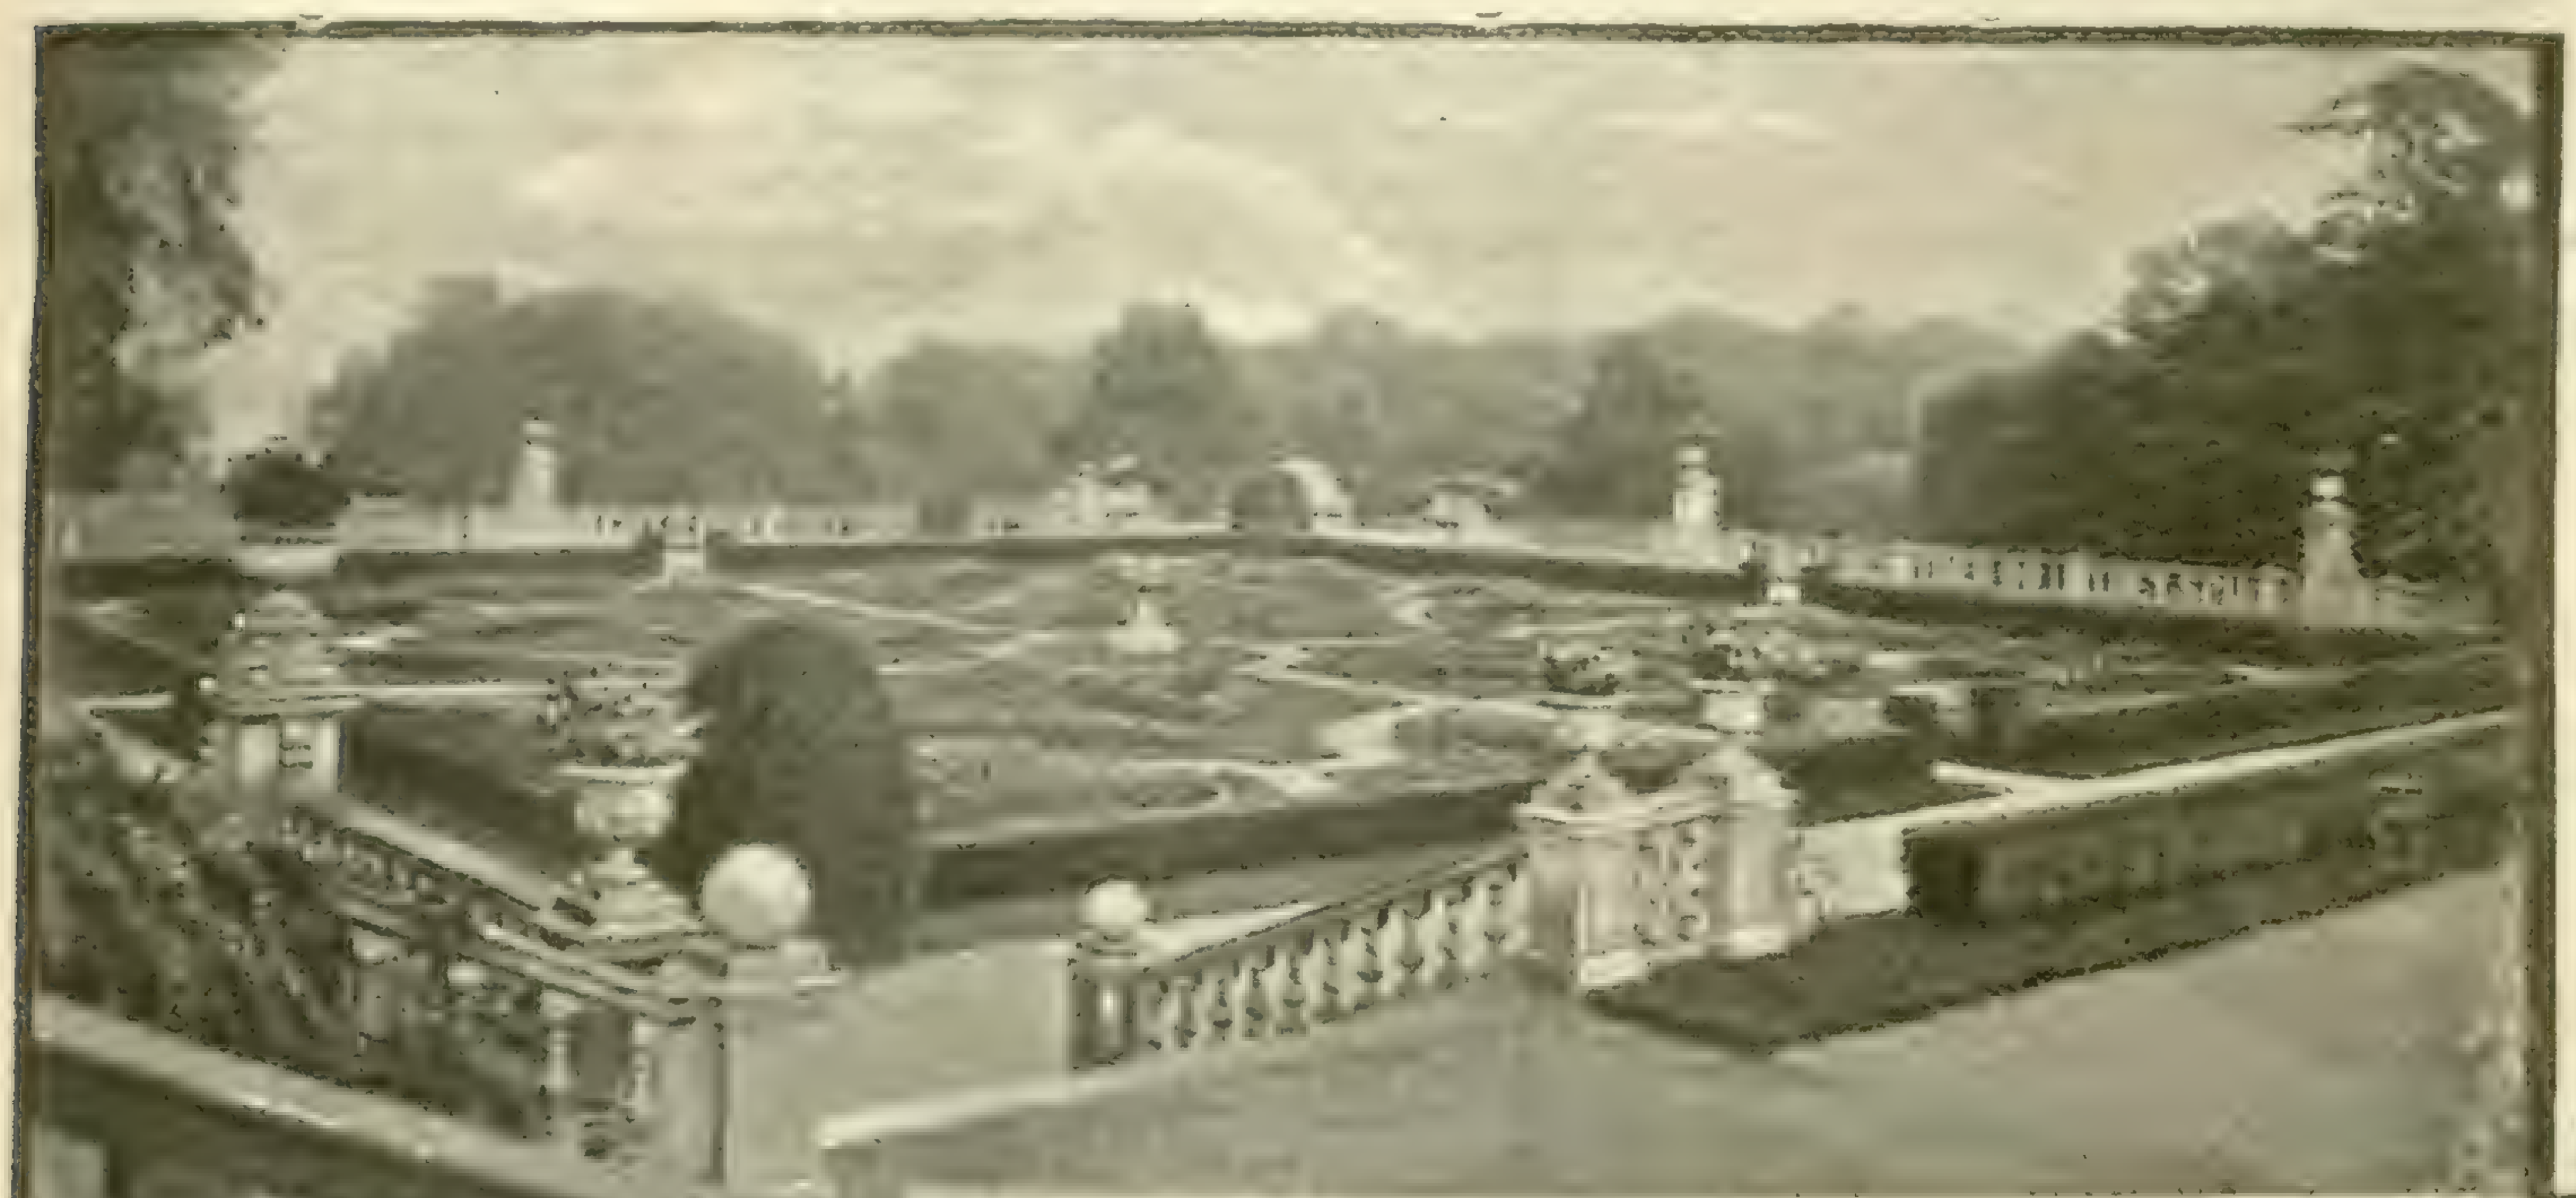
In connection with the arborescent features of Castle Ashby, it may be of interest to mention that the visitor should not fail to continue his journey to Yardley Chase, a fine open stretch of woodland, in which in bygone days the Plantagenets hunted and Cowper moralised. The Chase affords many pleasant walks through its green glades, but is of special interest as containing the remnant of the old oak immortalised by Cowper—who, it may safely be assumed, was an occasional visitor to this relic of the great forest that one time spread over a large portion of this part of Northamptonshire, for it is within a pleasant walk of Olney, long the residence of the poet. Absolute accuracy is not an attribute of the true poet, and we therefore do not expect it in Cowper's "Yardley Oak." Were it otherwise, it would be necessary to point out that Cowper indulged in a full play of poetic fancy when speaking of this tree as—

> "Survivor sole, and hardly such, of all
> That once lived here, thy brethren at thy birth."

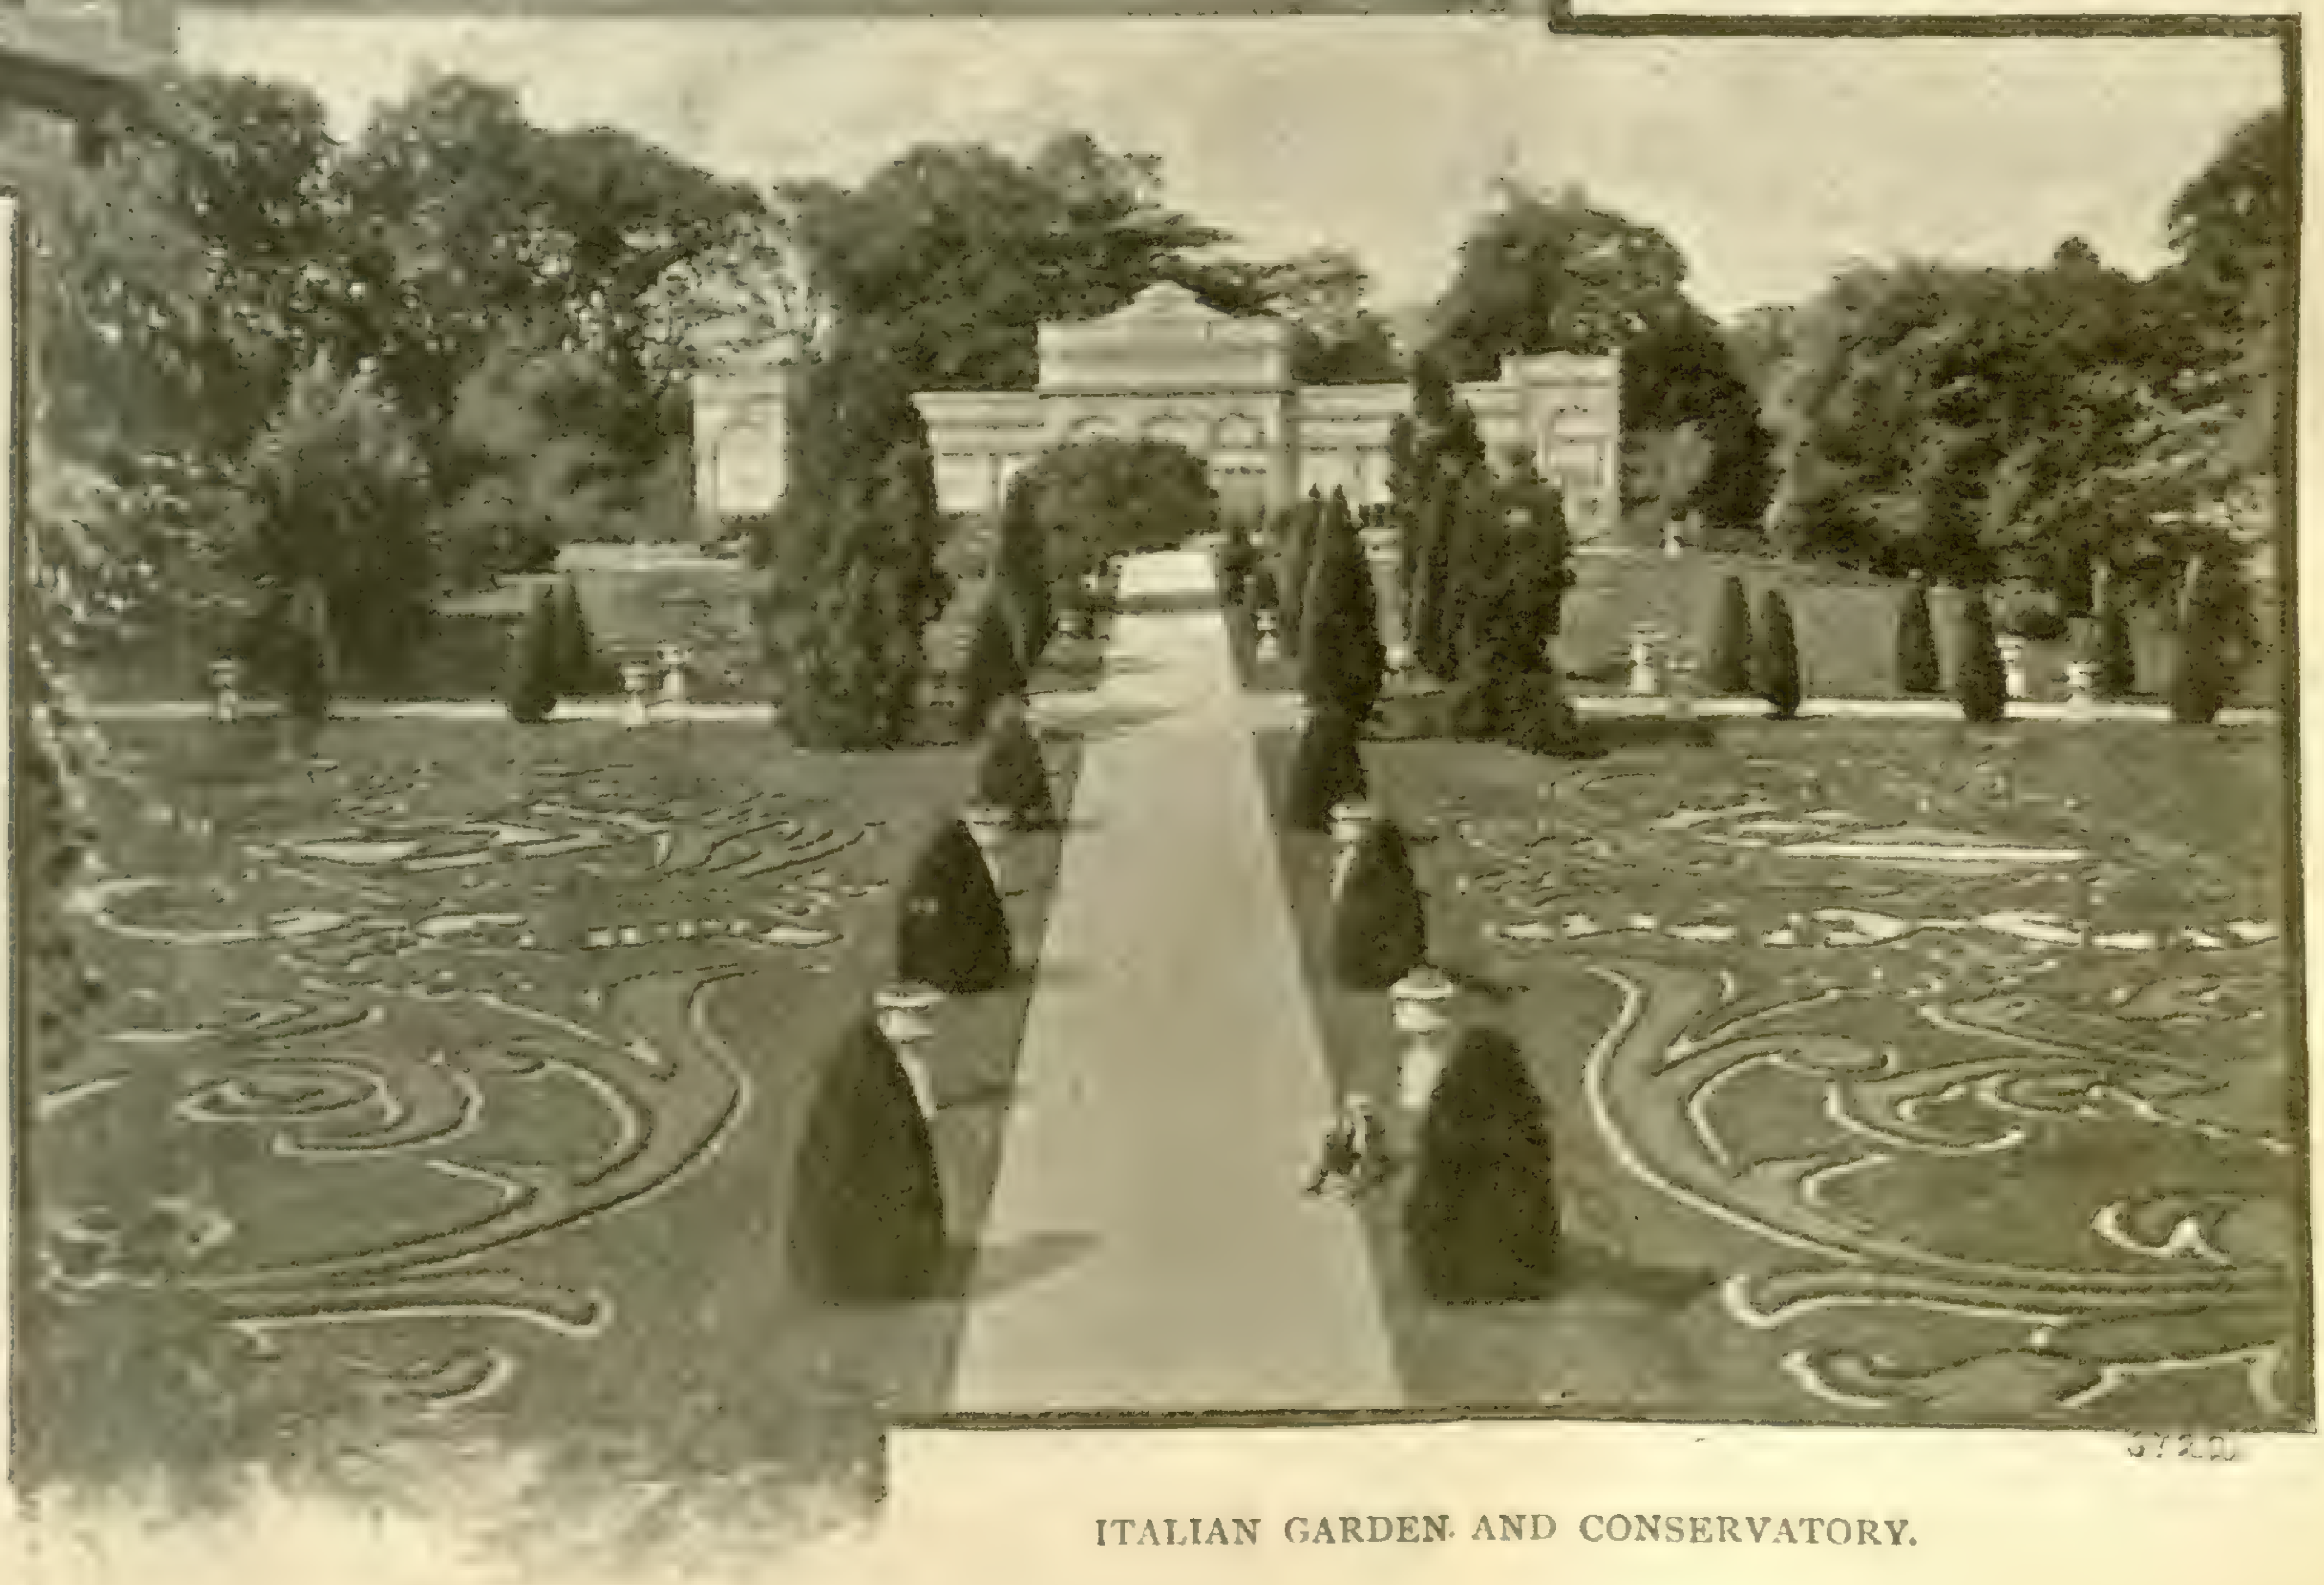
There are a trio of ancient oaks in the Chase, and the two known respectively as Gog and Magog, if not exactly the same age as "Cowper's" oak, may be properly regarded as contemporary with it, for they are of great age, and have long since passed into a state of picturesque decay. Of Cowper's tree but little beyond a mere shell with one or two arms remain, and in looking at its hollow, lichen-stained trunk, it is difficult to resist the temptation to moralize, and say, with Cowper,—

> "Time made thee what thou wast, king of the woods;
> And Time hath made thee what thou art—a cave
> For owls to roost in. Once thy spreading boughs
> O'erhung the champaign; and the numerous flocks
> That grazed it, stood beneath that ample cope
> Uncrowded, yet safe, sheltered from the storm
> No flocks frequent thee now. Thou hast outlived
> Thy popularity, and art become
> (Unless verse rescue thee awhile) a thing
> Forgotten as the foliage of thy youth,

As becomes a large establishment the structures for the cultivation of plants, fruits and flowers under glass are numerous, and form an important and eminently interesting feature. Chief among those devoted to ornamental plants is the conservatory, a spacious building of handsome elevation occupying a prominent position at the north end of the Italian garden, and so attractive within as to be a much-appreciated resort both of the friends of the noble owner and of visitors on the days when the gardens are open to the public. A glimpse is obtained of the conservatory through the archway; but its architectural features are best seen in the illustration of the Italian garden. Briefly described the lofty building consists of a central transept and side wings, and it has a handsome façade of stone similar to that obtained from the neighbourhood of Bath. The stonework is on the outerside covered to a considerable height with Austrian briars, which, as in the case of those trained to the walls of the mansion, bloom profusely and produce a glorious effect during the season of flowering. As will be seen from a glance at the full-page illustration of the interior there is a handsome fountain basin in the centre of the middle division, and that the low wall is divided into eight sections, four of which are provided with receptacles for plants. These are changed from time to time, according to the season of the year. During the winter and early in the spring they were filled with examples of Primula obconica, which were remarkable for the high quality of the strain they represented and the cultural skill that had been brought to bear upon them. When the photograph was taken the sections were occupied by white marguerites, and these in their turn made way in the course of the summer for zonal pelargoniums, or it may be tuberous begonias. The four groups of callas in the basin have occupied their present position for a long period, and they are evidently at home with their roots laving in the water, for they present at all times a luxuriance and produce an abundance of finely developed spathes. As a matter of course they have a large bank of soil in which to obtain anchorage, and this is probably partly renewed from time to time. Surrounding the fountain are huge orange, lemon, and citron trees in boxes, lofty tree ferns, chiefly cyatheas, Seaforthia elegans, and Dracæna australis, with an elegant undergrowth of ferns and flowering and ornamental-leaved plants of dwarf growth. A portion of the roof is draped with the elegant Tecoma jasminoides. For the most part, the plants employed in the ornamentation of the two wings are arranged in beds, of which there are three in each. The principal bed in each extends the whole length, with a broad walk on either side, and in these are planted the stately palms, tree ferns, New Zealand flax, and other objects that help to contribute to the permanent attractions of the structure. Conspicuous among the palms are finely-developed specimens of Corypha australis, Chamærops excelsa, Phœnix dactylifera, P. rupicola, and several kentias. Especially noteworthy also in the central beds are the specimens of Phormium tenax variegatum, which have leaves ranging from eight to ten feet in length, and are admirably coloured throughout. In the borders on the outer side of the walks are arranged the plants of scandent habit with which the roof and wall spaces are clothed, and here were several so remarkable for their development as to justify an expression of surprise by those possessing a wide knowledge of the vegetation of temperate regions. Streptosolon Jamesoni has climbed the wall to a height of twenty feet or so, clothing the masonry on its way, and then spread over the roof, and suspended in the air large clouds of its rich orange-coloured flowers. Many splendidly-developed specimens of this handsome species have come under my notice since its reintroduction, but in no case has its ornamental character been more strikingly exemplified than in this instance. Cantua dependens, Habrothamnus coccinea, Styrax officinalis, Ruscus androgynus, and Pittosporum tobira are also employed with good effect for clothing wall spaces, training up pillars, and draping the roof. Highly attractive also during the summer season are the specimens of Brugmansia Knighti and P. sanguinea, which have noble heads,



LOWER TERRACE GARDEN



ITALIAN GARDEN AND CONSERVATORY.

and produce during July and August enormous numbers of the large trumpet-like flowers. Additional brightness is imparted to the side divisions by the free use, as in the centre, of flowering plants according to the season.

To the right and left of the stately arch which is the subject of one of the illustrations, and forms the southern entrance to the Italian garden, are ranges of plant houses less ornate than is the great conservatory, but of handsome elevation and highly attractive by reason of the excellent condition of their occupants and the taste shown in the arrangement. On the eastern side of the archway one of the structures, with a length of nearly fifty feet and a width of eighteen feet, is devoted almost exclusively to Fortune's Yellow rose, and well does this beautiful tea-scented variety pay for the space and time devoted to it. There are three specimens, and these fill the whole of the root-space and form overhead a dense canopy of the richest green, and produce the richly-coloured flowers in remarkable profusion. Last year the crop comprised five thousand blooms, and that number will probably be exceeded this season, for early in March upwards of three thousand blooms had been cut. This fine old rose is seldom seen at the public exhibitions; but it is satisfactory to know that it is being more largely planted under glass for the production of cut flowers for decorative purposes. We have now many beautiful teas that are well adapted for culture under glass, but there is not one that, having regard to freedom of flowering and attractive colouring, can be said to surpass it. Of its value no better proof could be desired than is to be found in these great gardens. There are also some fine specimens of Luculia gratissima in the rose house, which bloom with great freedom, and the stone pillars along the front of the house between the sashes are clothed with the most elegant of the scented-leaved pelargoniums.

The structures on the opposite side of the archway are devoted to stove plants, and are artistically treated with a view to presenting the occupants in a more natural manner than is possible in structures provided with stages in accordance with the orthodox plan of arrangement. The general collection is planted in borders, of which there are three in each house, the principal one being, as a matter of course, along the centre. The back wall is covered with a dense growth of ferns of various kinds, chief among these being the davallias and nephrolepis, and it may be useful to mention that the general effect of the wall is considerably heightened, more especially during the spring months, by the bright red tints of Nephrolepis Bausei. The narrow wall spaces between the glass panels are clothed with ferns and ornamental leaved begonias, and suspended from the roof are numerous well-filled baskets of adiantums, davallias, and other ferns. In the beds are large specimens of Caladium esculentum, and fine masses of cannas, and to the pillars are trained Begonia fuchsioides and B. President Carnot, the huge clusters of flowers of the last-named being especially attractive. There are necessarily many houses devoted to the preparation of plants for the decoration of apartments and the conservatory, and for the production of cut flowers. To particularise these would require much space, and it will suffice to say that all classes of plants best suited for decoration are grown in immense numbers, and in a manner that reflects the highest possible credit upon the skill of Mr. Hayes, the able chief of the gardens. Crotons, of which Volutus, Œerstedi, and Laingi appear to be held in the highest estimation, are grown by the hundred, while of the richly coloured Acalypha Macafreena several hundred plants are propagated annually, so highly appreciated is it for dinner-table and other decorations. Contiguous to the rose garden is the show house, which has recently been rebuilt, and here may be found at all times a bright display of greenhouse plants grown for their flowers. In the structure are fine examples of Cassia corymbosa and Brugmansia suaveolens well deserving of mention, but of special interest are the examples of Abutilon vexillarium trained under the rafters. With the main stem trained to the rafter and the side growths allowed to hang down naturally, the plant presents, with its myriads of pendant crimson and yellow flowers, a surprisingly beautiful appearance.

Fruit houses are even more numerous than are those devoted to plant culture, and would justify even more space being devoted to them than is now possible. The first range to obtain attention contains seven houses built in accordance with the views which obtained among garden architects half a century or so ago, and therefore more lofty than is now considered desirable. In this range are excellent examples of fig and grape culture. The most popular of the figs is Brown Turkey, which is grown both planted out and in pots. The Black Hamburgh and Muscat houses have been replanted within the past two or three years, and the vines are making so satisfactory a growth as to suggest many years of usefulness. In another part of the gardens is a large span-roof mixed vinery, and in this Lady Downes, Alicante, Madresfield Court, Black Hamburgh produce heavy crops of finely-finished clusters annually. Six or seven houses are devoted to peaches, and these are so arranged as to ensure a continuous supply of fruit from early in the year until quite the end of the season for these luscious fruits, and the supply is not only continuous, but abundant and of high quality. The favourite peaches are Alexandra Noblesse, Royal George, Hales' Early, Raymacker, Early Alexander, Dymond, Goshawk, and Barrington; and the nectarines held in the highest estimation are Rivers' Early, Lord Napier, Stanwick Elruge, and Victoria. It was interesting to observe that all the houses contained early and late varieties, as it is found that when this is done there is less risk of overlapping or breaks in the supplies than when each structure is devoted to varieties ripening simultaneously. Large as is the number of houses devoted to the cultivation of fruits and ornamental plants, it is evident that they are no more than sufficient to meet the demands that are made upon the garden, for every foot of space that can be utilised in the fruit houses without interfering with the permanent occupants is occupied with strawberries, French beans, and ornamental plants, of which specially large stocks for bedding or other purposes are required. In the frame ground are forcing houses wellnigh innumerable, and in these the crops of cucumbers, melons, and tomatos were of exceptional merit. The walls of the frame ground are covered with tea and noisette roses, the two principal varieties being Vicomtesse de Vezins and William Allen Richardson, both of much value for giving liberal supplies of flowers for cutting.

Within the walls the area devoted at Castle Ashby to the cultivation of vegetables and bush fruits is upwards of five acres, but this is not the whole of the space devoted to these useful crops, as a second garden some acres in extent is utilised for the production of vegetables. The entrance on the northern side of the kitchen garden forms the termination of the broad promenade that runs through the conservatory and Italian gardens, and the department is consequently in direct communication with the ornamental grounds and plant houses. The kitchen garden is enclosed within lofty stone walls, surmounted by a broad coping formed with red tiles, which is picturesque, and no doubt useful in protecting the trees from adverse influence in spring. The area is divided into four equal portions by roads of sufficient width to admit of manure and other material being carted on to the quarters, which are again divided, for convenience of working into two or three parts by secondary walks. At the extreme or southern end of the garden is a large semi-circular space raised two feet or so above the general level, surrounded by a seat and divided into beds, filled with herbs. Gooseberries and currants are grown as multiple cordons, and the practice adopted is to plant two trees about two feet apart and to so arrange the branches of each as to form a circle. Grown in this manner these fruits are said to crop much more heavily than when grown in accordance with orthodox practices. Raspberries are trained to a wire trellis, and of the several varieties grown, Superlative is considered one of the best. The main walks are flanked by rows of pyramidal and bush trees of apples, pears, and plums, and the walls are covered with fan and horizontally trained fruit trees of various kinds, those of pears and plums predominating and yielding an ample return for the space occupied.

It so requently happens that the house provided for the head gardener, and the accommodation for the young men, are out of keeping with the mansion and its surroundings, that it gives me special satisfaction to mention the fact that at Castle Ashby, both gardener's house and bothy have been planned with due regard to appearance and comfort. An illustration is given of the residence of Mr. Hayes; and with reference to the bothy, it may be said that while of handsome elevation it is highly convenient, and so arranged as to ensure a maximum of comfort for the occupants.

Mr. Hayes, who is responsible for the management of these great gardens, has occupied his present position since the death of Mr. H. Birch, nearly five years; and although, comparatively speaking, young in years, has shown such remarkable ability in every department, as to fully justify the anticipation that the high reputation these gardens have so long enjoyed, will, under his direction, with the generous support of his noble employer, be fully maintained if not greatly enhanced.
